I am very desirous of inducing the students to draw. It is by the pencil that an architect learns as well as designs, and if it is possible to stimulate the use of the pencil to any extent by what passes in this class-room, it will be most satisfactory to me and serviceable to yourselves. I trust that the sketches which I made on the black-board will be always copied in your notebooks, and that you will make sketches from the diagrams hung up. I shall continue the practice which Professor Donaldson established of lending the diagrams to students, and I shall be delighted if they are much borrowed and much copied, and I shall have pleasure in offering prizes for the best sets of sketches illustrative of the lectures A and B, and shall hope to find that there is a keen competition.

But the most serious part of my task remains behind. Can I teach the students not merely to know something about buildings or parts of buildings, or to draw them, but to understand them;—feel their value as works of art or as specimens of construction, and penetrate through the outward and tangible aspect of a material thing to that inspiring something—that reason, or design, or contrivance, or historic import which gives to a congeries of bricks and stones and mortar a value which in some cases is literally beyond all price? Can I make you understand why the choir of Westminster is lovely, or what the secret principles are which hang the fretted roof of its Lady Chapel in mid-air? Can I enable you to study, and to some extent comprehend, ancient designs, and so take the first step towards yourselves becoming designers? I do not know, but it will be my endeavour to do something of this sort, and if I can see that even to a very small extent I have been successful in making you think for yourselves, I

shall be far more satisfied than if I find your minds crammed full of facts and dates, and matters which can be learned by rote, and which it is often possible to know without understanding them.

The method of lecturing established by Professor Hayer Lewis will be continued, at least through this session. It is a method more serviceable to the student than agreeable to the Professor; but I believe it affords a very good means of learning what is taught, and reduces to a minimum the risk of mistakes in your notes. The plan is this: The notes of a portion of the lecture will first be dictated slowly, sentence by sentence, and are to be written down by the class as I read them out, and then, after this is done, I shall go over and explain the portion of the subject which the notes cover. This ought to ensure correctness in your notes, and gives an opportunity for revising them to a certain extent; but I value it chiefly because it leaves the students free to listen with their eyes as well as their ears (and, believe me, the eyes help you to understand wonderfully what is said, without being distracted by the effort to follow the lecturer and fill the notebook at the same time.

I may perhaps now and then vary this plan for a single lecture. Occasionally, at any rate, it will be desirable for you to hear, and me to give you, a connected discourse not disturbed by the breaks to continuity which such a system entails. I shall be sometimes glad, especially when trying to show you the principles that underlie architectural rules or practice, to be as uninterrupted as possible, and you will probably be the better for having occasionally to give continuous attention. When this is done I will take care that an outline of the heads of the lecture is provided for each of you, so as to leave you free to follow me.

It has been the custom, and one which I hope to follow as an additional means of interesting and instructing the classes, to take the students to one or two of the great buildings of London and to some large builder's yard, when the opportunity will occur of seeing in actual fact some of the matters which form the subject of our lectures, and where, perhaps, the habit of examining buildings and works in progress may be encouraged, and the method of investigating ancient work learned.

A notice of the method pursued here would be incomplete were I to omit the examination and prizes. The examination, the results of which determine the prizes, takes place at the close of the session: it is entirely in writing or by sketches, the questions being printed, and the prizes are publicly presented at the College. An alteration has been made this session, by which the work of the entire year will be treated as one whole. Formerly it was divided into two portions, and the arrangements were such that only half the work done by a student was the subject of the final examination. An attempt to remedy this last year by holding two examinations was found inconvenient in practice, and this time the examinations at the close will cover the work of the whole session in each class. An examination, properly looked at, is an admirable feature in a course of instruction. It enables a student to recognise the progress that he has made, and compels him to make some use of what he has learned. I shall probably, therefore, introduce one additional examination during the session in each of the classes A and B, not to be counted towards the award of prizes, but solely for the purpose of aiding students. Let me add that it is most desirable that every person attending the class should attend the final examination, and do his best to obtain, if not a prize, at least a certificate. The prizes given include two silver medals given by Professor Donaldson, and bearing his name, together with valuable prizes of books. The certificates are given to as many students as obtain a certain proportion of marks out of the total possible; and it is fair here to point out to you that the best way of obtaining a good proportion of marks is not to write long answers, and to bring in irrelevant things which the student knows, but which form no part of the correct answers to the question—but to write accurate and clear replies which shall on the one hand answer every part of the questions, and on the other, shall not travel beyond the questions, and to illustrate them, wherever possible, by well-drawn sketches. Where an answer is given, wholly or partly, by a sketch, I always,

in marking the paper, first allot as many marks to it as would have been due to a correct reply in writing, and then add something more for draughtsmanship if the sketch shows any merit.

Thus far it has been my aim to show to you, gentlemen, what this college has been doing for years past, and what I, as its professor, propose to endeavour to do in the coming session for such of you as become students. I must not close without some remarks upon what you must do for yourselves, and upon the degree in which our work here may be an aid to you in that which occupies you during the greater part of your time.

I have already said that in an office you learn practice—in the classroom you learn principles. If this be so, it is not difficult for you to see that as you master principles here, you will find they enable you rapidly to get a firm hold upon practice elsewhere.

Take the most important branch of your work, in the office or out of it—your drawing. The arrangements of these classes do not, it is true, provide for instruction or, except just incidentally, for practice in drawing; but there is hardly a part of either the construction or the architectural treatment of a building which you will not draw far better when you know the reasons for its taking the shape it does. The simplest parts of your work, the working out of plans, will explain what I mean. The beginner is often in difficulties as to the thickness of brick walls. I hope, when he has been through the part of this course which refers to brickwork, that the sizes of bricks and the mode of combining them into walls, will be made clear to him for life. Another illustration may be taken from a more advanced sort of work. The elevation of a building ought to have—I think will have—more interest for a student who knows something about the features employed, than if he simply copy them unintelligently. For example, if the Orders occur, he who knows something of how and where they originated, what their earliest forms were, and where they were matured, will draw with more understanding and pleasure, and will, therefore, be sure to draw them better than one who only knows that he has gone through a rather irksome task in drawing them out after some typical example. The man who has some general acquaintance with the forms of architecture and its history, will be prepared to deal with whatever period or style he has to work at, as something not quite strange to him. The same thing is true of materials and construction. When, for example, you understand the reason of the shapes and relative sizes of the timbers in a roof, and why their joints are shaped as they are, and what purpose each part has to serve, you will feel more interest in drawing such roofs as you may have to put into plans, and you will undoubtedly draw them with fewer mistakes. When you have been told what are the main peculiarities of the leading building stones, or the sorts of timber most used, and when you know what marks indicate good quality, and what the reverse, you will not only find a walk round a building instructive, but may soon become able to make yourselves useful in aiding, to some extent, in the superintendence of buildings. At any rate, after having mastered some of the elementary principles of materials or of construction, you will be able to take in and assimilate the information which the accidents of practice bring within your reach.

As a general rule, I believe that a young man who has already spent some months or a year in an office is more likely to get benefit from these classes—especially from the Construction class—than one quite new to the subject. On the other hand, I believe, as I have stated, that to a youth just fresh from school or college, the opportunity of some systematic and scholastic teaching on subjects connected with his profession is of importance—so much so as to outweigh any disadvantage arising from his being new to the subject. A student so circumstanced should attend the Art class, and that only, in his first year, and should take the Construction class the year after. If, however, a student has been a year in an office (much more if he has been a longer time) it may be advantageous to him to attend both classes in the same year. This is, however, partly a question of the amount of time he can give to

the work at home which attendance here involves.

I hope it will be distinctly understood, and always borne in mind, that the student who wishes to get real benefit from these lectures must devote some time to them at home each week, besides attending his hour here. The notes should be carefully written out in ink—from the rough notes made in the room—and the sketches made from the black-board should be carefully and neatly copied into the permanent note-book. The books named should be consulted; but most and chiefly, everything connected with the subject of the lectures of which illustrations can be found should be drawn. The diagrams afford a mine of wealth of this sort, and the generous practice of lending them, under proper restrictions, to copy affords an opportunity of making the fullest use of them. Much information may be gained by copying, sketching, or reducing these diagrams; but the student who wishes to make the most of his opportunities should also draw or sketch such illustrations in other books, or such photographs, or such pieces of actual work as come under his notice, and are of a nature to elucidate the subjects being treated. I have had the pleasure to see excellent sets of illustrative sketches in previous sessions, and I repeat that I sincerely hope this may be the case in the present session.

Allow me to express my hope that most, if not all, students will attend the Art class. I believe it to be of the greatest possible importance, and that attendance at the Science class alone is a very incomplete and one-sided mode of education, even for an engineer or a surveyor, much less for an architect. It is hardly possible to convey to you how keenly a critical observer is sometimes made to feel the disgraceful want of knowledge which English architecture too often betrays. Features which are inaccurate are constantly to be met with in designs, otherwise so simple, that a very small amount of education would have insured correctness. Features that are incongruous are frequently put together, and spoil the effect of many a building which, had its author's cultivation only been such as his talents deserved, might have been a complete success. Of course, attendance in the Art class is no guarantee of correctness; but a very considerable amount of such information as no architect, no draughtsman, no civil engineer ever ought to be without, is put within the reach of the students of that class, and I can venture so far as to say that no young man of intelligence who has gone through the course and worked at it fairly and thoroughly, ought to be able—I think I may say would be able—to design such monstrous elevations and details as would be found, if we went to look for them, within a hundred miles of the centre of this great metropolis.

As to the Professional Practice course, it is not designed for beginners, and probably few students who have been less than three years in an office will be able to reap the full advantage of attending it; while, I hope that to many who are much more advanced these lectures may be serviceable. They have been attended during the short time that they have been given by architects in practice as well as by senior students, and, as already explained, they will be directed specially to the requirements of those who are beginning, or are hoping soon to begin, practice.

In conclusion, perhaps, I may be pardoned if, passing away from the subject which has occupied our attention, I say one or two parting words about work and study outside these walls; in fact, I feel as if I could hardly close without some allusion to your own studies. Many topics might be touched upon; but I will limit myself to a passing remark or two upon each of four: Drawing, Practical Work, Books, and the Study of Ancient Buildings.

Before anything else, it is of importance to you to draw—and to draw well. You ought to be able to represent, fairly well, anything you see. And if you wish to attain this power nothing is so useful as studying the human figure. The Slade school here is the best school for the purpose that I know; but those who cannot give the time in the day-time, may be able to draw at one of the schools of art where the antique is studied in the evening.

With your drawing instruments you ought to be able to work as easily as an ordinary draughtsman using the pencil alone. To laud

the tee-square and dividers thus readily requires long practice; but till this facility is completely attained, the instruments will always be a little in your way. Long before that time, however, you ought, so far, to master the use of them that all your ink lines shall be true and even, all your circles really round, and all your right lines really straight; and if this degree of steadiness has been perfectly mastered in a student's first twelve months, it is a not discreditable performance, and perfect command of the instruments will follow in time. Practice sketching things you see, especially portions of buildings; and, in short, strive to become, in every sense of the word, skilful, artistic, and rapid draughtsmen. Above all things, practise yourselves in designing. The power of originating architectural compositions may be latent in many of you; but effort is as much required to bring out that power as to make manifest any other latent capacity or gift. Design is fostered by study; but a man may be studious without a particle of inventive power, or may perhaps neglect invention for the attainment of knowledge, and by so doing impair his ultimate success as an architect. Practise designing therefore.

Next in importance to drawing comes practical work of any sort. The most useful of all is to go into a workshop and learn to make something belonging to a building. By the time he has become able to make a four-panel door, a youth can gain such an acquaintance with construction as will prevent his making half the mistakes which disfigure most working drawings turned out by young hands. But whatever piece of practice of any sort is within reach, examine it, and get a share in it. The commonest office work done intelligently may impart valuable knowledge. To trace drawings or copy specifications, if only the young clerk determines to understand all that goes under his hands, is a means of gaining all kinds of instruction, and a six roomed house, if only it be watched closely from day to day, would afford a fund of information as to materials and construction. Do not, therefore, neglect or despise the humblest opportunity of seeing or sharing in any sort of practical work which comes in your way.

The use of books has already been considered at some length. I should like to suggest that the student should not only by degrees form a library of the best books of reference (taking care to get the best), and that what he buys he should read; but that he should make use of the fine public libraries accessible in London, and in not a few of our great towns. There are a few good architectural books in the library of this college, free to students. There are some, I believe, at Sir John Soane's Museum; and the three great art libraries of the Royal Academy, the South Kensington Museum, and the Royal Institute of British Architects, supplemented by the Library of the British Museum and the loan library of the Architectural Association, furnish the London student with the means of consulting every book of reference that exists, and every illustrated treatise on our art, with little inconvenience, in some instances at absolutely no expense, and in other cases at a merely nominal fee. Do not, therefore, neglect the magnificent opportunities for making use of good books which exist within your reach.

Last, but by no means least, comes the study of ancient buildings. This is alone the source of inspiration and of accurate knowledge for the architect. Set it down in your minds that your best opportunities are those which give you time to measure or sketch some good example of English or foreign architecture, and that your training will remain incomplete unless one good long journey, or more than one shorter one, shall have enabled you to study examples on the Continent of Europe as well as English ones. It is not buying prints and photographs which puts knowledge into your minds; it is the process of patiently watching, examining, and, so to speak, absorbing the peculiarities of your subject while you draw it, that enables you really to know it; and, let me add, this is much more thoroughly accomplished by the process of making a set of geometrical drawings from the solid work than by representing it in a perspective, however cleverly and prettily that may be done.

If the variety and extent of study which is here hinted at—prolonged, as it ought to be, through a series of years, and, in fact, more or less kept up through life—

seem formidable, let me remind you, that the profession of an architect is not an easy one, and that it is only by unremitting, careful, and studious work that the student can fit himself for the discharge of its various duties and render himself equal to its responsibilities. But in almost every department of these studies there is much to interest and even to fascinate the mind. There is hardly any amusement undertaken for pure pleasure which is so enjoyable as a sketching tour through a district rich in works of architecture. There are few occupations where the anxieties and hard work inseparable from all the real business of life are lightened by so many occupations of a kind which it is a pleasure to engage in, and none, so far as I know, where the advantages of variety of employment are so fully enjoyed. A calling such as you will find architecture to be, if you heartily throw yourselves into it, demands that those who engage in it should fit themselves for it by sufficient training and assiduous study. It will be my part to attempt to offer to my students a portion of this training, and I trust that those of you who join my classes will come prepared to study with such assiduity as to command, as well as deserve, success.

SPECIFICATION OF IRONWORK.

IN the specification of ironwork it is very useful to know what are the market forms and qualities. By specifying for the brand and trade-mark of a well-known maker, the purchaser or engineer may be protected from imposition, though it is not seldom that with the utmost care he may suffer from the trickeries and fallacious marks known only to the trade. There are certain tests which only good wrought iron can stand, and these ought to be known. Bar-iron, for instance, may be notched and bent cold to show the fibre. B and BB bars should stand a tensile strain of 22 tons per square inch with the grain of the iron, or 18 tons crosswise thereto. Flat bars not exceeding $\frac{3}{4}$ in. thick may be bent with the grain to a radius of $2\frac{1}{2}$ times their thickness without fracture; they should also be able to stand punching and drifting without fracture. Engineers require certain tests; one of the best is to find the ductile quality by the amount of contraction of the area of section before tearing asunder under a tensile strain. Kirkaldy's experiments have shown that the contraction of area at fracture is an essential element in estimating quality, and is more reliable than the breaking strain. For both strength and ductility, the iron for structures should be specified not to break with a tensile stress less than a given amount, and that before breaking it ought to elongate not less than a certain proportion of its original length. The measurement for elongation is soon found, while the reduction of area at fracture is not so readily determined. The iron which shows the greatest tensile strength is generally the hardest, but has the least ductility or power of stretching; but both these qualities are necessary in certain members of a bridge. For plate-iron, the bending tests, when hot, are useful as rough tests. Plate-iron may be bent either hot or cold, with or across the grain, and the angle through which the plate should bend without cracking depends on the thickness and quality of the iron. According to the Admiralty tests BB plate-iron, grain lengthwise, $\frac{1}{2}$ in. thick and under, can bend 120° when hot, and from 15° to 70° cold, the last angle being for $\frac{3}{4}$ in. plate. Crosswise, with grain, the plate will bend, when hot, to 90° , and from 5° to 30° cold, according to the degrees of thickness from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. For B plate, the angle bent through is 90° hot, and from 10° to 55° cold, while crosswise of grain, the angle through which the iron can be bent is 60° when it is hot, and it will bend from 5° to 20° cold from $\frac{3}{4}$ in. to $\frac{1}{2}$ in. thick. The angle referred to is that through which the plate is bent from the horizontal. Rivets of good quality should double when cold without fracture, and their heads ought to be capable of being hammered down without cracking when hot. Again, the physical appearances of iron ought to be known. Wrought iron, when suddenly broken, presents a crystalline appearance—when gradually a fibrous one; but it has been shown that good iron may be either crystalline or fibrous, according as the stress which caused fracture was sudden or gradual. Bad iron is never fibrous, but no

criterion as to quality can be arrived at without knowing how the iron has been treated, and the strains have been applied.

Bars are round, square, or flat, and the ordinary sizes are $\frac{1}{2}$ in. to 3 in. diameter, or sizes increasing by 1-16 in. Flat bars are generally from one inch by $\frac{1}{4}$ in. to 6 in. by $\frac{1}{2}$ in., the width increasing by $\frac{1}{4}$ in.

Among the sections kept in stock are half-round, oval, convex, octagon, and hexagon. Such bars can be had up to 22 ft. in length without extra charge. Ordinary bars are sold at usual rates from $\frac{1}{2}$ in. to 3 in. wide; below these dimensions the rates increase 5s. to 10s. per ton for every 1-16 in. reduction. Above 3 in. the prices also increase. Bars of L or T-shape are rolled from $\frac{1}{2}$ in. to 8 in. wide. For sections thinner than $\frac{1}{2}$ in., 10s. to 20s. extra per ton is usually charged, and the same increase is incurred for sizes over 8 in. wide. In most of the large manufacturers' lists, however, sections of every useful size can be obtained at ordinary rates. Most of these forms of iron can be obtained in lengths up to 40 ft., above which a few shillings more per ton is charged for every 5 ft. of extra length. This length, of course, depends on the rolling-mills, which vary from 20 ft. to 40 ft. for L bars, and 20 ft. to 30 ft. for T bars. It is stated on good authority that the iron in L bars is of better and more uniform quality than that in T bars, as the pressure in rolling is more equally applied. Channel iron, used in lattice girder bridges, is made of several sizes, but the rolled iron joist or I-shaped girder is one of the most useful sections in construction, and is manufactured in a variety of forms, proportions, and sizes. It is rolled in depths of from 3 in. to 14 in., but every manufacturer publishes his own sections, with the weight per foot run and the distributed weight each section will bear. The uses of this favourite section are too well-known to need mention; it may be remarked that its employment for fireproof floors and large roofs on the Continent increases yearly. Small and narrow sections are the cheapest. Beyond 9 in. deep and 4 in. wide the price increases from £1 to £2 a ton. If wider flanges than 6 in. are required, the price is greater. For constructive purposes joists of more than 12 in. deep are better in riveted iron, though sections up to 20 in. deep are used on the Continent, and by riveting two sections together, either side by side or vertically, rolled joists of this section can be applied to almost any ordinary purpose. As regards length, the small sections are rolled up to 25 ft. without extra charge, and the larger sections up to 20 ft.; beyond these lengths the price often increases, and lengths up to 40 ft. are now commonly supplied at little additional cost. These joists are generally cut to the required length, hot as they leave the rolls; if cut to a length, cold, a sum of a few shillings per ton extra is charged. Architects who require to specify these forms of iron do well to find out the dimensions kept in stock by merchants before writing; these vary, but lists are generally obtainable giving sections with weights and every particular, which may save much useless trouble and calculation.

The memorial-stone of a Sunday school now in course of erection near the Upper Brook-street Free Church, Manchester, was laid on Saturday. The school has been designed to harmonise with the church, which is in the Early English style, and was built some 40 years ago, from the designs of the late Sir Charles Barry. The whole of the elevations are faced with stone, and a feature has been made of the octagonal staircase, which faces Upper Brook-street. The work is being carried out by Mr. Herd, of Ardwick, from the plans and under the superintendence of Mr. J. W. Beaumont, architect, of Manchester. The estimated cost of the school is about £2,200.

At the seventh half-annual meeting of the New-haven harbour company, held on Friday, a report was received from the engineer (Mr. F. D. Baister), stating that the capital expenditure for the improvement of the harbour, including purchase of property, now amounts to £198,716. The breakwater, which is intended to be 3,000 ft. in length, now extends 700 ft. seawards, and concrete blocks for the foundation have been deposited for a further length of 200 ft. The new eastern quay is nearly completed, and the two new eastern piers to harbour will be finished during the ensuing autumn. 118,000 tons of mud have also been dredged from the harbour during the half-year. Mr. Carey is the resident engineer of harbour works, and Mr. H. Jones, surveyor to the company.

ALBERT HALL MANIONS, SOUTH KENSINGTON.—RESIDENCE
FOR G. NODDER, ESQ., MILFORD MANOR ESTATE, SALIS-
BURY.—NEW MIXED SCHOOL, PENCOEED.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ALBERT-HALL MANIONS, KENSINGTON, W.

This building, which has lately been erected in Kensington Gore, is situated close to the Royal Albert Hall. Its scheme, being somewhat complicated, and therefore difficult to explain without diagrams, we publish herewith plans of two floors and a section, which will make clear the arrangements. On referring to the section, it will be observed that the front or north side is divided into seven stories, whilst the back portion has nine floors in about the same height. The object of this is to place the whole of the principal or reception-rooms so as to overlook Hyde Park, and by the lesser number of stories to obtain greater height, whilst the back of the building being occupied by bed and dressing rooms, kitchens, &c., a less height, such as 10ft. 6in. or 11ft., is for all practical purposes as good; and by this arrangement a considerable amount of accommodation is gained. The variety of levels which thus arise make the plans, unassisted by a section, difficult to understand. The portion already built, and shown in our perspective view, consists of three entirely separate blocks. In each block are eight large separate suites, and in the upper part eight smaller suites, which may easily be altered into four larger suites, if desired. Each of the larger suites is complete in itself, with front door opening from the principal stair, and back door from the service stair. Two lifts are provided: one for passengers, and one for coals, provisions, &c., situated close to the tradesmen's entrance. It will suffice to describe two floors, as all the others are very similar. The ground-floor consists of outer and inner entrance-halls, dining-room, and drawing-room, each 20ft. by 17ft.; three bedrooms and w.c. on same floor. A private stair leads up to three bedrooms, bath and linen room, w.c., &c., on entresol. In the basement, also reached by a private stair, is a kitchen and scullery, pantry, two bedrooms, larder, and coal-cellar. The rooms belonging to the ground-floor suites are marked in the plans and section by the letter A. The suites on the first floor have each outer and inner entrance-halls, a drawing-room, 20ft. by 17ft., and a dining-room, 21ft. by 17ft., two bedrooms, and a dressing-room on the same floor, and a private stair leading down to a kitchen, pantry, bed and dressing room. The rooms of this suite are marked B on plans and section. On the section the letter C shows the rooms of third floor, and D those of the fourth. Ample carriage and spare rooms are provided for all the suites in the basement. The whole of the work has been carried out by Mr. Thomas Hussey, of High-street, Kensington, from the designs of Mr. R. Norman Shaw, R.A.

RESIDENCE, MILFORD MANOR ESTATE, SALISBURY.
THE house illustrated upon the adjoining page has been recently built for Mr. George Nodder

upon the Milford Manor estate, which has been recently sold by the Ecclesiastical Commissioners. The building stands at the north end of the property, where it abuts upon the new road to Laverstock. The house is built of brick, faced with the Fisherton white bricks and Bath stone dressings. Messrs. Young and Sons, of Salisbury, were the contractors, their tender being £1,500, exclusive of the boundary-walls. The interior decorations have been tastefully executed by Mr. H. D. Martin, under the direction of the architects, Messrs. John Harding and Son, of Salisbury.

MIXED SCHOOL, PENCOEED.

THREE schools, which accommodate 170 children, were recently erected from the designs and under the supervision of Mr. Henry C. Harris, A.R.I.B.A., architect, Cardiff, by Mr. George James, builder, Bridgend, at a cost of £1,500, inclusive of furniture and boundary-walls. The materials used were red bricks and terra-cotta from the adjacent works of the Pencoeed Brick and Tile Company, for the walls, with small green slates for the roofs.

GEOLOGICAL MAPS.

FOR engineering purposes good maps are essential, and a map of a district with the physical features laid down is one of the first necessities. Hills, rivers, streams, geological boundaries, and heights above the sea-level ought to be shown, so that the line of any intended railway can be laid down in the most economical manner. Maps for this purpose are issued by the Ordnance Survey. One of these is drawn to a scale of 1 in. to a mile, and is large enough for a general indication or a preliminary survey; if greater accuracy and detail is necessary the 6 in. scale map may be used. The Geological Survey have also issued sheets of maps to the same scale, though some parts of the country are not yet published. The sheets to the larger scale represent about twenty-four square miles, and are about 18. to 68. persheet. In addition to these maps, geological sections are published to a general scale of 6 in. to the mile, traversing England and Wales, Scotland and Ireland in various directions. These are sold with descriptions in sheets, representing about 36 lineal miles, and numbered for reference. Contour lines are given on the large scale maps of the Ordnance. These lines, as may be imagined, represent all the points cut by a horizontal plane at certain heights. Contour lines convey in a very graphical manner to the eye, the physical conformation of a district—the hills and valleys are clearly indicated by the lines and their contour. The following principles ought to be remembered in using contour lines:—(1) The boundary lines of horizontal strata exactly coincide with the contours; the lines, in fact, may represent the boundaries; (2) The boundary lines of strata dipping towards a hill are less winding than the contours; (3) The boundary lines of strata dipping from a hill are more widening than the contours. From these principles it is easy to determine the boundary of strata, if the beds continue the same; but dips and "faults" interrupt a boundary line, and these require personal survey by the aid of borings and trial holes.

CHIPS.

In our account last week, on page 513, of the new sea defence works at Hythe, an error occurred. It should have been stated that the works were carried out from the designs of Sir John Coode, under the superintendence of Mr. H. D. Good, C.E., of Dymchurch. The constructor was Mr. H. B. James, C.E., of Westminster.

Mr. F. A. Fawkes, author of "Horticultural Buildings," has been retained to give a course of three lectures at the Crystal Palace School of Gardening, at 5 p.m., on Nov. 16th, 23rd, and 30th, to the students and the public, on the construction, fittings, and heating of greenhouses and other horticultural structures. These lectures will be illustrated by numerous diagrams, &c.

A bazaar has been held in Walworth-road Wesleyan Chapel, Camberwell-gate, in connection with the reopening of the building after renovation and improvement effected at a cost of £1,000. Of this work Mr. Charles Bell, of Old Broad-street, was the architect, and Mr. Goad, of Camberwell, the contractor.

AN ELEVATED RAILWAY FOR VIENNA.

A PROJECT is on foot for constructing a circular intra-urban railway for Vienna, which, wherever it may be possible, shall be carried above ground on iron columns, with such improvements in the method of construction as may have been suggested to the engineers by their experience of railways of this kind already in operation in New York and Berlin, and one of more recent construction in Rotterdam. The length of the circular railway as projected is about 8½ miles (English), but it is proposed to make six branches, which would give it a total length of about 28 miles. These branch lines, diverging in various directions, would connect with the circular line (and so with one another), the termini of the other railway systems, the Government arsenal and storehouses to the south-east, and a system of tramways which it is proposed to lay down to serve the rapidly-growing suburbs to the south-west of the city. To meet the objections of the Viennese to anything which might destroy the beauty of their city, great attention has been paid to the appearance of the stations, viaduct, and other works, by Mr. Joseph Fogerty, M.Inst.C.E., the engineer of the scheme, under whose direction the details of construction and designs for stations, &c., have been prepared. It is proposed to erect a large central station in the Franz Josef Park on the right bank of the Danau Canal and near the Bourse. The building, to be 750ft. by 250ft. in width, would be of an ornate character, and to compensate the people for the loss of some of the public park, it is proposed to use the space under the railway platforms and offices of the station for a fish, fruit, and flower market, while the extension of the station at each end used for sidings, &c., would be converted into a covered children's playground, or devoted to other public purposes. A device is suggested for lighting the space beneath the stations, by forming the vertical faces of the platforms of reflecting lenses. At this point, too, wharfage accommodation would be provided for the steamboat traffic. There would be two other large junction stations, and 16 smaller stations on the circular railway. The roadway of the elevated portion of the line would be of open or griciron pattern, formed of large balks of timber on which would be laid heavy steel rails. It is believed that by adopting this method of construction the noise from the passing trains would be reduced to the minimum. This part of the line would be carried at an average height of 16ft. to 18ft. from the ground on cast-iron columns of 11 in. diameter, placed in clusters of three. They would be bound together in the centre, and connected at the cap and base in such a way as to render the use of "lugs" unnecessary—a point to which attention was specially directed by the Tay-bridge catastrophe. These groups of columns would be 60 to 80ft. apart, the lattice-girders on which the roadway would be borne being surmounted by a light ornamental railing. The width of the elevated portion is designed to be 28ft. over all. The principal streets would be crossed by arched ornamental bridges. For 70,000 tons of the ironwork which would be required, the custom duties being practically prohibitory of its importation, a provisional contract has already been made with the Witkowitz Iron Company, of Austria, represented by Messrs. Rothschild and Guttman, of Vienna. The locomotives, weighing 25 tons, would be of the kind introduced by Messrs. Lamme and Franck—fireless and charged with steam from stationary boilers. The cost of carrying out the scheme is estimated at from four to five millions sterling.

A public meeting, convened by the local builders, was held at the assembly-rooms, Richmond, Surrey, last week, to consider the building by-laws now under the consideration of the Richmond Vestry for adoption. Mr. A. C. Wylie occupied the chair; and after a report had been read by Mr. W. P. Goulding, F.S.I., a resolution was passed requesting the vestry to have the proposed regulations revised by some competent authority before being submitted to the Local Government Board. At a special meeting of the vestry, which has since been held, it has been decided to make several alterations in the by-laws, in order to meet the objections raised to them by builders.

GLASGOW INSTITUTE OF ARCHITECTS.

THE fourteenth annual general meeting of the Glasgow Institute of Architects was held on Tuesday, Mr. John Honeyman, F.R.I.B.A., the president, in the chair.

Mr. William MacLean, writer, the secretary, read the annual report:—The New Municipal Buildings competition, referred to in last year's report, again occupied much of the attention of the Council. The Lord Provost requested the Council to formulate their suggestions for the guidance of the committee charged with framing the conditions for the new competition, and a reply was sent to his Lordship in the following terms:—"The Council of the Glasgow Institute of Architects having now given the subject most careful consideration, beg, in response to your Lordship's invitation, to offer the following suggestions: (1) The mode of conducting a competition most likely to induce architects in large practice to compete, and, therefore, most likely to obtain for the promoters a large number of meritorious designs, is this—To invite architects to submit sketch designs in the first instance, the drawings being limited to a plan of each floor, two sections, and two elevations, all drawn to the scale of $\frac{1}{16}$ in. to 10ft. No premiums to be offered, but the authors of the designs adjudged best, to the number of not less than six or more than ten, to be invited to prepare fully matured designs to a larger scale, illustrated by any kind and number of drawings they may please. Each competitor furnishing such designs to be paid a fee of, say, £200, and the author of the design ultimately selected as the best of these to be appointed architect of the new building. (2) In the event of the more usual course being adopted, we do not advise that the total amount of premiums offered should be greater than in the recent competition; but we recommend that the sum should be sub-divided to a greater extent, that the first premium should not exceed £400, and that there should be not fewer than five other premiums. (3) It is immaterial whether the wishes of the Corporation as to accommodation are communicated to the competitors by means of plans or by printed instructions, so long as the kind and extent of the accommodation desired is clearly defined; but it is of the greatest importance that competitors should be left absolutely free to arrange the accommodation in any way they may think best. 4. In the event of our first recommendation not being adopted, we are of opinion that competitors should be required to send in the following drawings—viz., a plan of each floor, two sections, four elevations, and as many additional drawings, not being perspectives, as competitors may think necessary to illustrate their designs; it being a condition that all these drawings must be to a scale of $\frac{1}{16}$ in. to 10ft. We consider it to be, on the whole, best that no perspectives be allowed. The way in which the drawings are to be finished should be distinctly stipulated, and any violation of the conditions in this respect, or in any other respect, should disqualify a competitor, who should have his drawings returned to him immediately on such violation being ascertained. So long as the instructions are perfectly explicit, it is of comparatively little consequence what style of drawing is prescribed; but we are disposed to recommend that the plans and sections should be tinted with sepia or China ink only, and that the elevations—including portions shown in elevation on section—should be drawn in line only with China ink, that they should be without shading of any kind, and that the windows and other openings should be darkened by a uniform wash of China ink, without shadows, but of such depth as each competitor may think best. 5. We think the Classic style of architecture most appropriate for the intended building. 6. We strongly recommend that the stipulation as to cost should be rigorously adhered to, and, therefore, earnestly advise—(1) That the Corporation should particularly specify everything which they intend the stipulated sum to cover; and (2) that before deciding upon what that sum should be, they should ascertain as nearly as possible what a building of the size contemplated must necessarily cost, and then allow in addition to that an ample margin for suitable architectural embellishment—nothing being more likely to lead to trouble and dissatisfaction than restricting the stipulated limit of expenditure unduly, while no greater mistake can be com-

mitted than to suppose that such undue restriction conduces to ultimate economy. 7. It is important that the conditions should be so framed as to leave no doubt as to the intention of the Corporation to appoint the successful competitor architect of the new buildings at the usual rate of remuneration. There may be good reasons why he should not be so employed, and, therefore, there must be some reservation to prevent the Corporation being actually bound to employ the author of the best design; but what is essential is that the profession should be satisfied that it is the *bona-fide* intention of the Corporation to employ any honourable and competent man who may be declared to be the successful competitor, as any doubt about this would prevent many men of good standing from competing. 8. We recommend that a professional adviser, or professional advisers, should be employed by the Corporation to assist them in the selection of designs. 9. With the view of preventing canvassing and the divulgence of mottoes, we think it advisable that the distribution among members of the Town Council and others of reduced drawings or photographs of competition designs, should be prohibited by express stipulation. In conclusion, it may be said that the success of your appeal to the profession, as indicated by the number and professional standing of the competitors, will be chiefly affected by the quantity of work required of them, the liberality of the terms offered, and especially the evidence of *bona-fide* interest in respect to the employment of the successful competitor and the provisions for securing fair-play; and the character of the result, satisfactory or otherwise, will depend (1) on the precision, definiteness, and practicability of the instructions and conditions; and (2) on the strict fidelity and impartiality with which, guided in all respects by these conditions, the judges act. On only two other points shall we now venture to offer an opinion:—(1) That it is exceedingly desirable and likely to be advantageous to the Corporation that abundance of time should be allowed for the preparation of the designs, and (2) that competitors should not be required to crowd too much upon the site. Assuring your Lordship of the willingness of the Institute to co-operate with your committee in any way you may consider practicable and expedient, in name and by authority of the Council of the Glasgow Institute of Architects (signed, JOHN HONEYMAN, President; WILLIAM MACLEAN, Secretary." It will be observed that those recommendations are in all important particulars identical with the recommendations which the Lord Provost obtained simultaneously from the Council of the Royal Institute of British Architects, and it is very gratifying to find that this expression of professional opinion has guided his Lordship's committee in framing the conditions of the present competition, which have given such general satisfaction. The proposed restoration of the west front of St. Alban's Abbey having been brought under the notice of the Institute by Mr. T. L. Watson, a remonstrance was sent to the Dean of St. Alban's in the following terms:—"That the Institute strongly disapprove of any unnecessary destruction of the Mediaeval portion of the west front of the Abbey, and protest against the proposed reconstruction according to the design illustrated in the BUILDING NEWS of 26th November last." It was resolved at the beginning of this year not in the mean time to invite competition for the Institute Gold Medal or President's Prize, as the competition has never been engaged in heartily by the assistants, whom it was intended to benefit and encourage. It is hoped that after the lapse of a year or two without competitions a greater number will avail themselves of the advantages thus offered. In the mean time, those who really desire to distinguish themselves in this way have an opportunity of competing for the prizes offered to members of the Glasgow Architectural Association, and for the prizes offered by the Royal Institute of British Architects, and they should receive every encouragement to engage in these competitions. The council having, on the invitation of the Leeds Architectural Association, considered the expediency of the obligatory examination of all candidates for admission to the Royal Institute of British Architects, recommend that members of the profession who have given proof of distinguished abilities, and who are otherwise eligible for admission to the Institute as Fellows, should

not be absolutely debarred from becoming members because at the outset of their career they neglected or failed to gain admission as Associates; and that therefore in the event of any rule being adopted making examination a necessary preliminary for admission in all grades, it would be expedient that full provision should be made for dealing with exceptional cases. The Master Masons' Association invited the advice of the Institute regarding proposed modifications of the existing rules and regulations for the measurement of mason-work in Glasgow and neighbourhood, which they propose adopting with the acquiescence of architects, measurers, and builders, and the secretary procured a copy of the proposed rules for each member of the Council. This important subject is at present engaging the attention of the Council, and their report will shortly be laid before a general meeting of the Institute. The Council desire to commend this subject to the earnest consideration of every member.

The President, in moving the adoption of the report, said that the proceedings of the Institute seemed to be becoming every year more interesting and important, and he thought he might venture to say that this year's report showed the usefulness of their association more clearly than any other which had preceded it, and amply justified their appeal to those architects—he was glad to say they were not numerous—who were eligible for admission and had not yet joined them. It was quite clear that as mere isolated individuals they could exert but little influence as architects when matters of public interest were under discussion; and they must all be sensible that friendly intercourse with other similar bodies—with their brethren in London, Edinburgh, Leeds, Paris, and Amsterdam—would be impossible without their union, and their recognition as one of the professional incorporations of the country. At the conclusion of the report, allusion was dimly made to matters which would occupy much of their attention during the session now commenced, and which could not be satisfactorily dealt with without a free interchange of ideas and co-operation. The municipal buildings competition need not, he hoped, take up more of their time—and in reference to it he would only pause in passing to allude to the courteous manner in which the Institute had been treated by Lord Provost Ure—and to express a hope that their next report would record the appointment of one of their number as architect of the new building—it could not be himself, he was very sorry to say. But year by year new topics required their consideration. That which seemed to be more immediately pressing was the question brought formally before them by the Master Masons' Association regarding the measurement of mason-work, and there were other questions connected with contracting demanding attention.

The reports were adopted.

Mr. John Baird moved that the Council of Management for the year consist of Messrs. Hugh Barclay, 136, Wellington-street; Campbell Douglas, 266, St. Vincent-street; John Gordon, 124, Bath-street; John Honeyman, 140, Bath-street; William Landless, 227, West George-street; D. McNaughton, 140, Bath-street; John Murdoch, 48, Newmarket street, Ayr; James Sellar, jun., 266, St. Vincent-street; James Thomson, 157, St. Vincent-street; Robert Turnbull, 123, Wellington-street; and J. L. Watson, 108, West Regent-street.

Mr. Alex. Skirving seconded, and the motion was agreed to.

A meeting of the newly-elected Council took place immediately after the general meeting. Mr. John Honeyman was re-elected president; Mr. James Sellar, jun., vice-president; Mr. John Burnet, 167, St. Vincent-street, auditor; Mr. William Landless, treasurer; Mr. William McLean (of William and C. J. McLean), writer, 196, St. Vincent-street, secretary.

THE NEW TOWN HALL AT HUDDERSFIELD.

THE new Town Hall at Huddersfield, which has been built at a cost of £40,000, was opened on Tuesday. The building has been erected from designs which were prepared by the late Mr. J. H. Abbey, during the time he was the borough surveyor. At the commencement of the work, Mr. Abbey secured the services of

Mr. Frederick Wild, architect, Bradford, to whom he entrusted the whole of the designing of the working details in connection with the building. After the death of Mr. Abbey, Mr. B. Stocks, architect, Huddersfield, was appointed by the Corporation to act in the capacity of consulting architect, along with Mr. Wild. The style is Classic, of the Corinthian order. The pile occupies a site bounded on one side by Corporation-street, on the other side by Peel-street, and at the south end by Princess-street, while at the north end are the Municipal Offices, with which there is direct communication. For a building of such importance the situation is most unfortunate, lacking prominence and surroundings in which its proportions could be displayed to proper advantage. The height from the ground line at the centre of the main entrance to the top of the balustrade is 77ft. The entrance itself is 17ft. in height by 9ft. in width. The portico has four Corinthian columns and pilasters, which support the entablature. The windows, of which there are two, one on each side of the entrance, have granite columns. On the main floor front are columns 27ft. in height, with carved Corinthian capitals and moulded bases. The windows are circular-headed, three in number, the principal one in the centre having an elaborately carved and sunk head; they have also moulded architraves, carved key-stones, granite columns with carved capitals and moulded bases. The whole is surmounted by a moulded architrave and frieze, and large moulded cornice with moulded medallions and dentils, with moulded and sunk balustrade. The centre of this front, to the whole height of the building, containing the principal window and entrance, projects some 5ft. from the rest of the front. The side elevations are in harmony with the front, though neither so elaborate nor richly ornamented. With regard to the interior, the basement will afford ample cellars, and be also available for the detention of prisoners. The court-room is 38ft. long, 37ft. broad, and 20ft. high from floor to ceiling, the public entrance being from Peel-street, and the magisterial and official entrance from Corporation-street. A suite of rooms for the use of the Huddersfield School Board is also provided on this floor. The entire first floor is devoted to the Assembly Hall and its adjuncts. It is approached by the public from Princess-street by a flight of steps which lead to a vestibule 37ft. wide by 23ft. deep, having cloakrooms right and left. A flight of a dozen wide stone steps leads to a landing, from which branch right and left two flights of handsome stone stairs which conduct to a second landing from which the main floor of the hall is reached. This floor is 78ft. 6in. long by 60ft. 6in. wide, with a height from floor to ceiling of 55ft.; the area is about 4,750ft.; the hall, exclusive of the orchestra and gallery, contains about 260,150 cubic feet of space. This area is calculated to provide sitting accommodation for 1,100 persons. A balcony extends around three sides of the hall, and at a still higher level, but thrown back from the hall itself, is a gallery capable of accommodating 500 people. The hall altogether will seat 2,250 persons. The space under the gallery is utilised as a refreshment-room. The orchestra is 37ft. wide and 25ft. in depth, with retiring-rooms for speakers and musicians on either hand. It contains the whole of the latest improvements in mechanical contrivances, one especial feature connected with it being a sliding platform, contrived so as to make the stage larger or smaller, whilst the seats are all removable in sections whereby the stage can be used for operatic performances on a plan designed by Mr. Wild. The ornamenting of the hall generally and the colouring has been done by Mr. B. Dixon, of Bradford, and the designer is Mr. Wild. The hall is lighted by means of three sunlights, together with two light brackets. The building is heated with hot water.

TRAPS.*

By P. J. DAVIES, H.M.A.S.P., &c.

PRACTICAL EXPERIMENTS WITH CLOSET-TRAPS.

THE large amount of attention lately devoted to closet-traps by men of all classes is no novelty, as I can trace nearly four hundred

writers on this subject, some of them signing themselves S.E. (Sanitary Engineers), while only a few are content with the more modest title of Practical Plumber. The opinions of these writers are so various that it is quite amusing to read their different ideas, more especially when some of their drawings are examined. The recent sanitary agitation has resulted in a series of experiments with a view of testing the actual value of closet-traps, and I purpose in this article to give a description of these experiments and their consequences, though nothing in them is new to me.

Within the last fortnight there has been erected a scaffold some 50ft. high, fitted with 45ft. of soil-pipes and closet-traps, for the especial purpose of experiments. It has been my good fortune, when attending to test the various traps, to have met with some of the best plumbers now in business, as also members of the National Health Society, and it affords me great pleasure to have the opportunity of informing my readers of the various effects of the experiments on the different traps. "Some of the self-yept" "Sanitary Engineers" and

"Practical Plumbers" will be astonished at the result of these soundly practical experiments.

A. Fig. 1, represents a full-sized Sharp's pattern basin, 14in. wide and 12in. deep, fixed over a full-sized Pullen's cast-lead O-trap: the height of the soil-pipe from the basin A to the foot of the pipe is 45ft. The bottom of the basin was plugged, the basin then filled with water, and in spite of all efforts, and however much water was applied, when the plug was suddenly removed, the trap could not be emptied of water nor the water-seal destroyed, even when the cap G was made airtight over the top of the soil-pipe. On the opposite side was fixed an S-trap, and although we endeavoured to unseat this trap by siphonage from the O-trap, it was found impossible, although the cap G was quite airtight (the reason was simply because the dip or water-seal in the S-trap was 2 1/2in. against 1in. in the O-trap), therefore the necessary air rather went through the O-trap without affecting its water-seal.

For the next experiment some 2 1/2in. sq. stones were placed inside the O-trap, three of which were washed away by one basin of water. Then one teaspoonful of ink was placed in the

trap, which required two basinsful of water to thoroughly cleanse it.

A house-flannel 2ft. 6in. by 2ft. was put into the dip of the O-trap, and was thoroughly washed away with half a basin of water, so that the action of the O-trap can be certified as follows:—

That it cannot be siphoned out; no momentum of water would destroy the water-seal; a full-sized house-flannel will pass through it with half a basin of water; three stones, 2 1/2in. sq., will pass out by the impetus given by one basin of water, and—it cannot ebb or wave out.

THE HELMET TRAP (H, Fig. 2).

This trap has a rounded bottom, and holds considerably less water than Pullen's large O-trap, or the above-mentioned.

It was filled with water, and on raising the plug in the bottom of the basin H, it was found impossible, by any means, to destroy the water-seal.

Four pieces of brick and stone, 2 1/2in. square, were all carried before the water down the soil-pipe.

The house-flannel, 2ft. 6in. by 2ft., as also an extra piece of rag, 3ft. by 13in., were completely cleared by quarter of a basin of water; the one teaspoonful of ink was washed completely away by half a basin of water, the inference necessarily being that the Helmet trap is self-cleansing; it cannot be unsealed by siphonage; it will not momentum out; it cannot ebb or wave out.

BEARD AND DENT'S S-TRAP.

B, Fig. 1, is a closet basin, exactly the shape and size of A, Fig. 1. The trap was first filled with water, the basin plugged, the cap G taken off the top of the soil-pipe, and the basin filled with water. Then the plug was raised, and in an instant the water rushing from the basin cleared nearly the whole of the water from the trap, leaving a gap of at least 1/2in. below the throat of the trap, thereby at once leaving the trap totally devoid of water-seal.

Now this action, as described above, is very easily explained, and is that, owing to the shape of the trap and its having so smooth a surface, it cannot resist the impetus of the water from the basin when the plug is raised. This is illustrated at J, Fig. 3, by which it may be seen that the momentum of the water is carried forward, and to a considerable depth below the throat of the trap, at times even as much as 3in.; but as soon as the water breaks or parts upon the top at K, the hinder part of the water falls back into the trap, but in not nearly sufficient quantity to refill the trap, and so re-establish the water-seal. It should be remembered that water, like a ball, will proceed unless checked by another equal quantity (in one shape or other), having equal weight and power; but this not existing in the S-trap, renders it useless for the purposes for which it is intended, proving at once that the S-trap is unsafe for valve-closets or any other closets where large quantities of water have to be thrown down at one time, and is especially unsafe for housemaids' sinks.

The trap was then tried with the cap G replaced on top of the soil-pipe, and the action was precisely the same, and we could not get any more out than before. The trap L siphoned out when B basin was discharged. B basin trap will siphon out when a basinful of water is discharged down the top of the soil-pipe and the basin A plugged.

This proves beyond question that the O-trap will not only supply air enough for its own proper working, but enough for other traps that have a greater water-seal. It can afford to help others without interfering with its own efficacy. The additional tests of the O-trap were, that on placing five stones 2 1/2in. square in the trap, they were washed right away by one basin of water. The house-flannel was washed out with water running full bore from a 1/2in. cock (rate 4 gals. per minute) and was also washed out with a quarter of a basin of water. The teaspoonful of ink was cleared quite away with one basinful of water.

THE ECLIPSE TRAP.

This trap is shown at N I, Fig. 2. The basin being filled with water, and, as in the other tests, the plug suddenly raised, the water rushed through and left the water-seal broken, 1/2in. below the dip, although plenty of air was given

* All rights reserved.

through the soil-pipe. This was an undeniable proof that the fault of the trap consisted in momentum of the water, and not in siphonage, showing that it has the same fault as Beard and Dent's ∞ -trap, and therefore should not be used for valve-closets.

When tested with the stones, one basin of water cleared away four stones 2½ in. square.

One teaspoonful of ink required two basins to clear it thoroughly away.

This trap will siphon out by discharging the top basin, and having the top of the soil-pipe made air-tight, and having the other traps also made air-tight, but not nearly so readily as a Beard and Dent's ∞ -trap.

When the flannel test was applied, a quarter of a basin of water was found to wash the flannel right away.

I trust these experiments will be sufficient to prove my assertions that the ∞ -trap is the only reliable trap for valve-closet work, or any closet or sink where large quantities of water have to be thrown down at once, and that the ∞ -trap is quite unreliable for these same purposes.

I have some other experiments in hand, which will be reported upon as my papers in this journal proceed.

For the satisfaction of sceptics, I may say that architects, sanitary engineers, practical plumbers, and builders of responsibility may, on presenting their cards to Messrs. Pullen and Son, 73, Penton-place, Kennington Park-road, S.E., view the apparatus and test it for themselves.

E. R. in last number, p. 492, third column, read "bell-trap" (instead of "bell") on top line; third line read "this trap, Fig. 106."

THE TECHNOLOGICAL EXAMINATIONS OF THE CITY AND GUILDS OF LONDON INSTITUTE.

WE have before us the programme of the examinations issued by the City and Guilds of London Institute, for the year 1881-82. It is a bulky quarto of over 60 pages of printed matter. The Institute, we may here mention, affords facilities for carrying out an examination in any of the subjects it has enumerated of a technical character wherever a class of instruction is formed. A local committee must be found to undertake the examination according to the rules laid down; any art or science school committee under the department, any school-board or local examination board connected with the Society of Arts, is eligible. The examinations are in two grades: 1st. Ordinary (or pass); 2nd. Honours, the former are chiefly for apprentices and journeymen, the second for firemen, managers, teachers of technology, though both grades are open to candidates. The other rules are of not sufficient general interest to quote here. We may, however, say there is no limit of age fixed and no fee required, and intending candidates are invited to apply to the secretary of nearest local committee or the special local secretary for all information. The examinations are to be conducted by printed papers. Among the 32 different subjects enumerated, we find besides the useful arts of bread-baking, brewing, sugar manufacture, &c., the following having more or less direct bearing on building, art, and engineering—viz: Iron and steel manufacture, oil colour and varnish manufacture, gas manufacture, paper, pottery and porcelain, glass, dyeing and bleaching, photography, electro-metallurgy and textile fabrics of several sorts, lace manufacture, weaving and pattern designing, electrical engineering, metal work, plumbers' work, wood working, mechanical engineering, &c. Certificates and prizes are to be given to successful candidates in each subject. In the honour grade a silver medal and £5, and a second prize of a bronze medal and £3, are offered, besides five prizes of varying value in the ordinary grade. The syllabus of subjects of examination gives some useful information. Machine construction and drawing, building construction, applied mechanics, light and heat, and inorganic chemistry are required for the full technological certificate in both grades, or at least two of the above subjects are necessary in most of the branches. Taking iron and steel manufacture, the following subjects are required. 1st, composition and characters of chief iron ores; preparation of raw ores for smelting; 2nd, construction and mode of working blast furnaces, &c.; 3rd, nature of fluxes requisite under

various conditions, utilisation of cinder; 4th, hot and cold blast, effects of variations in amount of fuel and flux and on the production of the iron made; 5th, characters of pig-iron from various ores; general effects of foreign elementary substances. Production of spiegeleisen and ferromanganese; general chemical and physical distinctions between pig-iron, wrought-iron, and steel; methods of casting iron and steel; foundry appliances, furnaces, crucibles, and moulds; malleable iron castings; chilled castings; conversion of pig-iron into malleable iron; refining; puddling, manufacture of bars, rods, rails, &c.; conversion of malleable iron into steel; conversion of pig-iron into steel; Bessemer, Siemens, and other processes; machinery and other appliances; hardening and tempering of steel; case-hardening; welding, &c.; preparation of tin and tern plates, galvanised iron sheets, &c. The pottery and porcelain manufactures include questions on the various kinds of pottery, earthenware, terra-cotta, majolica, vitreous stoneware, white and brown; English porcelain, &c.; the chemical properties of the materials; glazes and their properties; pottery colours; majolica colours; the degree of heat required by each material; also as regards glazes, colours, firing, and improvements in ovens.

In metal-plate work, the questions include the chemical properties of the several metals, alloys, solders, and soldering, cutting of metal plate in the construction of geometrical and compound forms, various tools used, making pipes, joining sheet-metal, seaming, riveting, zinc-laying, roofing. In plumber's work the examination has reference to the properties and qualities of lead, zinc, and tin, of iron, white and red lead, cements, &c., the action upon lead, zinc, and tin of air, of different qualities of water, acids, sewage gases, &c.; solders; plumber's tools; manufacture of metals into various forms; cast sheet-lead, milled sheet-lead, rolled zinc, galvanised iron, lead tubes, &c., gas-fittings, measurement of pressure of gas of a main or pipe; sanitary arrangements of dwellings, testing drains and soil-pipes, water-closets, screen boxes, waste-water preventers, closets, sinks, &c., water supply for houses, cisterns, filters, water meters, storing rainwater, &c.; roofing; varieties of traps, ∞ -traps, ∞ -traps, &c., ventilation of soil-pipes and drains, sizes of pipes, and fall required. Among the works of reference recommended are Buchan's "Plumbing," Eassie's "Healthy Houses," Dr. W. H. Corfield's "Laws of Health," Miller's "Chemistry," Vol. II. In each branch, the subjects required and works of reference are given.

The questions to be given are printed at the end of the programme, and will be found of service to intending candidates.

SLATE QUARRYING.

AT the usual meeting of the Liverpool Engineering Society on Wednesday week, a paper on "Slate Quarrying" was read by Mr. C. H. Darbishire, Assoc. M. Inst. C. E. The paper dealt chiefly with slate quarrying as carried on in the Nantlle Valley, and the several beds or veins of slate that are worked therein. The author commenced by alluding to the rock as having been formed of great deposits of mud in water, composed chiefly of silica and alumina, which have been subjected to immense pressure and volcanic convulsion. The split of the slate is attributed in a great measure to the effects of the great pressure. The paper further described the several means of opening quarries whether on the hill sides or on the flat, and alluded to the different lifting apparatuses in common use, advocating inclines instead of the old fashioned guide ropes and hauling chain. Attention was called to the system of bargains under which practically all roofing slates are made, as well as the duties undertaken by the rockmen and quarrymen respectively, and their tools. The ordinary sawing machinery was described, as well as the dressing machines in vogue, preference being given to the one invented by the late Mr. Greave. The explosives mentioned were powder, nitro-glycerine, dynamite and gun-cotton, all being more or less employed with the exception of nitro-glycerine, the use of which has now been almost entirely abandoned. In pure slate the common black powder only is burnt. The author concluded by pointing out that a quarry venture is not necessarily a success

because there happens to be some good splitting slate found therein, but he thought that if sufficient good rock is found few ventures are so safe, or so lasting.

OUR COMMONPLACE COLUMN.

PICT'S HOUSES.

PICT'S HOUSES are numerous in the north of Scotland. Sometimes they are excavations covered with boughs or turf, as found in Aberdeenshire, Caithness, &c. Many of these dwellings are found in groups, about 7 ft. or 8 ft. diameter, and are oval in plan. These subterranean dwellings are also called *weems* and earth-houses. A large number of them were found near Kildrummy Castle, 30 ft. long, and 8 ft. to 9 ft. wide, formed of stones 6 ft. long, and vaulted over in horizontal layers. A *weem* is described in Barry's "Old Statistical Accounts," xvii., 237; also in his "History of Orkney." See "Thomas's Account of the Celtic Antiquities of Orkney" in *Archæologia*, 1852; Maule's "History of the Picts"; Ferguson's "Rude Stone Monuments"; also BUILDING NEWS, 1870, p. 139.

PICTURE-GALLERY LIGHTING.

THE proper lighting of picture-galleries has long been a vexed question among architects, painters, and connoisseurs. Sir C. Eastlake, Papworth, Redgrave, Statham, and others have contributed reports, and written papers on the subject, and we refer the reader for information to the Report of the Commission on Lighting Picture Galleries by Gas, 1859, reported in this journal, Vol. V. 689, and the reports by the Select Committee on the New National Gallery, 1850, and to plans of the Sheepshank Gallery at South Kensington; the Dresden and Vienna galleries; those at the Louvre, Munich, Berlin, &c. Galleries are lighted either by side lights or by top lights, and for small pictures side lights placed tolerably high are sufficient. In larger galleries, top or skylights are more necessary, and are generally provided. There seems to be a consensus of opinion that side lights placed high and regulated by blinds from the bottom of the window are equal in all respects to top lights, and several of the best Continental picture galleries have side lights. We may mention as instances the galleries at Berlin by Schinkel, those at Vienna, the Louvre, &c. As artists adopt usually a side light, and paint under such a condition, it is thought, and reasonably so, that such lighting must be the best. Central skylights are, however, usual in all large galleries, and we may mention the galleries at Burlington House, the National Gallery, the Suffolk-street and Dudley Gallery, and especially the new Grosvenor Gallery, all in London, as affording types of this arrangement. The principal point to observe in designing a picture-gallery is to so arrange the top lights as to throw the light on the walls without causing glare. A rather novel method of accomplishing this was suggested some years ago in *Gazette des Architectes*, 1870, by a French architect (M. Jules Bourdais), which consisted in introducing light from the roof, so as to fall only on the wall surfaces to be covered by pictures. For this purpose a series of diaphragms or screens, more or less opaque, were used according to diminution of light required on the other parts. These screens are placed between the inner and outer roof-timbers, or between glass ceiling and roof-lights, and are made of gauze, calico, or paper on light frames. When circumstances permit, the angle of direction of rays and of the diaphragm should be between 50 and 70 degrees. In treating sections of galleries lighted on this principle, oblique lines are drawn at the most favourable angles for admission of light, and the glass panels in ceiling and roof are formed between these oblique lines. The Pinacothek, by Voit, is another ingenious way of admitting light. The cross section of the gallery of that building consists of a centre with a span roof of rather flat pitch, and on each side above the eaves rises a clerestory, with a lean-to from its top to an outer wall. By this arrangement the rays enter through the clerestory lights above the centre roof, and fall upon the outer wall where the pictures are hung. Reflection is the great object to be avoided in proper lighting, and the angle of admission and height of picture must be so arranged that the observer does not look at the

pictures in the direction of the reflected light. Buckingham Palace picture-gallery is well lighted, and the light is admitted through a raised lantern-light. Its dimensions are 180ft. by 36ft. Dulwich College has a good picture-gallery 144ft. long by 20ft. wide and 20ft. high. The Grosvenor Gallery, one of the largest and best in London, is 104ft. long by 35ft. wide, and the small gallery is 60ft. by 30ft. The longest new galleries in the National Gallery, by the late E. M. Barry, are 120ft. by 40ft., and 100ft. by 40ft. We refer to a list of the dimensions of other galleries given in "Arch. Dict.," and for particulars, to the BUILDING NEWS, where several recent examples are described and illustrated.

PIER, THICKNESS OF A

BRIDGE piers in the best examples vary in thickness from one-seventh to one-eighth of the span of arch. Neully-bridge piers are one-ninth the span. The mathematical principles of the subject will be found discussed in Mosely's "Mechanical Principles of Architecture and Engineering," Professor Rankine's "Applied Mechanics," Tarn's "Science of Building," and in Campin's "Treatise on Materials and Construction." The stability of a pier of masonry depends on its resistance to overthrow, measured by its weight multiplied into the distance from the outer edge at the base from the centre of gravity. But the stability of a pier to resist lateral pressure, as that of an arch, can be determined by graphical means, or the application of the parallelogram of forces. The resultant of thrust should for safety pass through the middle third of the base of pier or abutment to give a factor of safety 3. For cylindrical piers the rules are given in Campin's work; and the student will find articles on the subject in the BUILDING NEWS. The artistic treatment of piers is discussed in the BUILDING NEWS, 1869, p. 517.

PILE.

In pile-driving, the pile ought to be driven to such a depth as to insure resistance to the proportion of load it is likely to bear, allowing for stress caused by lateral pressure of wind and other causes. It has been stated on a good authority that if a pile 1ft. diameter does not advance more than 2-5ths of an inch under a series of ten blows from a monkey weighing 12 cwt., falling a clear height of 12ft., it will be able to bear with safety a permanent load of 25 tons. It must also be remembered, the energy of a heavy ram may be expended in crushing the pile instead of forcing it downwards. The size of pile, its material, and the nature of soil, are important elements which must determine the weight and fall of the ram. "A heavy ram and a moderate fall will do more effective work than the same aggregate force with a lighter ram and greater fall" (Matheson's Aid Book). The point of a pile should be exactly true with the centre line, or the pile is apt to go on one side.

PILLARS—STRENGTH OF IRON.

CAST iron is generally used, and the hollow pillar is lighter, stronger, and more easily cast than the solid form. The greatest care is necessary to keep the core concentric, so that the thickness may be the same all round. Calculations to ascertain the strength of iron pillars will be found in all works on construction, and Hodgkinson's experiments show the relative strengths of pillars of different sections. No rational theory of resistance to compression has been yet found, and the formulae we possess are deduced from experiment. The iron selected for pillars should have a high modulus of elasticity, for the greater it is the less is the deflection. In making calculations the thinnest part of the column must be taken. For cast iron cylindrical columns, solid or hollow, with flat ends, the formula is the following:—

$$W = \frac{36}{1 + \frac{r^2}{400}}$$

For rectangular columns with flat ends—

$$W = \frac{36}{1 + \frac{r^2}{500}}$$

In these formulae W = breaking load in tons per sectional square inch; r = length divided by least diameter. We also refer the reader to the paper in the "B. N.," 1869, p. 476, and to the columns of Intercommunication.

PIPES—IRON.

PIPES are generally of cast iron for water, gas, steam, &c. They are made with flanges or socket and faucet ends. The former are best for steam and high-pressure water, the latter for gas and ordinary water service. The core should be 'quite concentric, so as to have a uniform ring of metal. If the spigot end is slightly tapered and the socket end also bored to that shape, closeness of jointing is insured, and a smearing of white lead or Portland cement is all that is required to make a tight joint. Such jointing is, however, desirable only when the foundation is uniform and unyielding; in other soils the joints are liable to be fractured, and the caulking of wide socket-pipes is more safe. Turning for both spigot and flange pipes is preferable, as waste of water is saved. Among the modes of joining metal pipes is the flange joint, with a ring of vulcanised indiarubber screwed up between: it makes a good hot water or steam-tight joint. For faucet pipes, iron cement is the best material; the cement is forced between the joints with a caulking chisel and hammer. A very tight joint is made by turning the flanges of pipes quite flat and making a groove in each for a ring of wire, which is then screwed tightly between. Pipes of iron are generally tested by hydraulic pressure equal to a column of water 250ft. high. The thickness of a cylindrical pipe exposed to internal pressure, according to one formula, should be $x = \frac{p r}{c}$ p being

pressure persquare inch; r = radius of internal diameter; c = cohesive strength of the metal per square inch. Another rule, Hawkley's, makes the thickness of the cast-iron pipes equal to one fifth the square root of diameter (Burnell). Another authority states a pressure equal to a column of water 300ft. high (130lb. to the sq. in.) is generally adopted and sufficient for cast-iron pipes. A vertical position for casting is now recommended for pipes over 3in. in diameter. The socket is cast downwards to allow uniformity of metal. Cast-iron pipes are made 9ft. long when the diameter does not exceed 12in., beyond this and up to 48in. a length of 12ft. is usual. Socket-pipes cost, for all diameters above 3in., £3 to £4 per ton above the current price of pig-iron, the price of pig ranging from £2 10s. to £3 per ton. If the sockets and spigots are turned, 7s. to 15s. per ton extra is required. Rain-water pipes are as thin as can be cast; they have socket joints, and are sold by measure of length. Pipes for high temperature system (Perkins's) are usually 1in. in diameter, about 2in. inside and 1½ in. or nearly 2in. outside. They are proved to about 3,000lb. per square inch. See Fairbairn in the "Resist. of Iron Tubes," Hurst; BUILDING NEWS, 1871; Matheson's "Aid Book."

The following is a clause that has been introduced for testing pipes in specifications for waterworks:—"The pipes, after being jointed and for a while uncovered, shall be from time to time tested in such lengths not exceeding 180yds., and at such pressures not exceeding the actual working pressure due to the head of water by more than 50 per cent., as the engineer may consider advisable." One mode of testing is to apply the pressure until it reaches the limit specified, then to carefully inspect each pipe in the trench at the sockets and joints. If a joint sweats, the caulking tool should be used while the pressure is on. When the defect occurs in the pipe itself, the pressure is withdrawn, the water run off, the joint cut out, and a new one inserted with a collar joint.

At a meeting of the lands committee of the Yarmouth town council, on Tuesday, it was resolved to recommend that body to subscribe £30,000 towards the proposed dock, near the entrance to the harbour. The area will be about 10½ acres, and the cost, exclusive of land compensation, sidings, and warehouses, £70,000. The docks will be 1,100ft. long and 400ft. wide, with a depth at high-water of 21ft., and 18ft. at low-water. The length of quays will be about 4,000ft.

Mr. G. E. Chapman, surveyor and inspector of nuisances to the Newhaven local board, last week sent in his resignation of the latter office, on the ground that his duties as a surveyor were sufficiently onerous to occupy his time and attention. The board resolved not to accept the resignation of one office without that of the other, as they considered one man could discharge both.

Building Intelligence.

HANLEY.—On Monday the foundation-stone was laid of the New Tabernacle Church Buildings, Hanley. These buildings are being carried out from the designs and under the superintendence of Messrs. William Sugden and Son, architects, of Leek, whose plans were selected unanimously by the committee at the close of last year in a competition limited to Messrs. Sugden, Mr. J. O. Sulman, F.R.I.B.A., London, and Mr. Ellison, of Liverpool. Messrs. Sugden submitted a Classic design, with tower and dome, and two designs in English Perpendicular Gothic, one of the latter being the one which is being followed in execution. All the intricate stonework of the front is to be executed in red Hollington stone, except some of the more exposed parts, where the adamantine Roche stone from the Leek district is being used. The walls of this front are faced externally with specially made local thin red bricks, and the roofs are covered with brown Broseley tiling. The tracery of the side windows will be chiefly of red terra-cotta, of similar character to the stone tracery of the front. The following is a summary of the accommodation provided: Chapel, with north and south transepts and galleries on three sides, containing 1,000 sittings; extreme length, including rostrum apse, 81ft., width 48ft. width across transepts 69ft., height in centre 42ft. Lecture-room, containing 200 sittings, length 43ft., width 29ft., height 23ft.; organ-chambers both to chapel and to lecture-room; tower and entrance porches, and two main staircases, one descending to the school-floor; and narthex 24ft. long and 8ft. wide, with double swing glass doors; entrance-porch to lecture-room and for girls' approach to school; a boys' porch and two porches to classrooms; minor staircase, behind rostrum apse, for the minister and choir; minister's vestry 16ft. by 12ft., with lavatory, &c.; deacons' vestry, 20ft. by 12ft.; large schoolroom, 55ft. long, 41ft. wide, 28ft. high, with clerestory; library, 21ft. long by 17ft.; infants' schoolroom, equal to about 33ft. by 16ft.; mothers' meeting-room, 20ft. by 17ft.; eight boys' classrooms, each 12ft. by 10½ft.; five girls' classroom, each about 13ft. by 9½ft.; one young women's classroom, 25ft. by 13ft., and two smaller ones; young men's classrooms, tea-room, scullery, heating apparatus vault, lavatories, separate for boys and girls, ample corridors, &c. The contractor for the erection of the buildings is Mr. Samuel Warburton, of Harpurhey, Manchester.

HUDDERSFIELD.—On Thursday week a new chapel, which has been erected at Partown, Huddersfield, for the Wesleyan Methodists, was opened. The building, which is dedicated to the Holy Trinity, was designed by and has been erected under the superintendence of Mr. Arthur Smith, architect, Queen-street, Huddersfield, his plans and designs having been selected from a number of others in open competition. The style is Early English, and the edifice is built of pitch-faced wall stones, from Elland Edge, with Crosland Hill ashlar dressings. At the rear there is the minister's and stewards' vestries, each 14ft. long and 12ft. wide; and a classroom 19ft. long and 14ft. wide. The chapel will accommodate 750 persons. The following are the contractors:—Masons, Messrs. S. and G. Brook, Bradley; joiner, Mr. David Light, Leeds-road; plumber, Mr. George Slater, King-street; plasterer and slater, Mr. W. E. Jowett, Huddersfield; painter, Mr. Thomas Robinson, Ramsden-street; ironwork, Mr. James Brook, New-street; and heating apparatus, Messrs. W. and S. Thornton. The total estimated cost, including extras, is £5,000.

LAWRYOLYN.—Christ Church, Lawrytyglyn, S. Wales, was opened on Thursday week. The church consists of nave 43ft. by 20ft., chancel 17ft. by 20ft., with vestry at S.E. corner 10ft. by 9ft.; and porch 7ft. 6in. by 7ft. 6in., with tower over N.E. corner. It is built of local grey stone, with Cefn freestone dressings to the angles, windows, and coping. The roof is open-timbered, and covered with Machynlleth slates; the seats are of pitch-pine varnished. The aisle and chancel are laid with ornamental encaustic tiles. The tower is of three stages—porch, ringing-chamber, and belfry: the last being surmounted with open oak tracery framing, with ornamental weather louvres, capped with gilded vane. The

style is Late Decorated Gothic. The architects are Messrs. Jones and Parke, of Newtown; the builder is Mr. E. Williams, of Newtown.

LONDON.—The City Press office, and printing establishment of Messrs. W. H. and L. Collingridge, has recently been rebuilt upon the site of the premises destroyed by fire last year. The style is Jacobean, the ground-floor portion being executed in red and grey polished granite; the upper stories are in red Corsehill stone, having circular bays over each entrance, the whole being finished with a Mansard roof, and ornamental cresting, with dormers springing from the top cornice, also in Corsehill stone. The whole of the casement-lights are in wainscot, fitted with Smith and Stevens' "Janus" sill bars and watertight fastenings. The late Mr. John Collier was the architect, but owing to his decease during the progress of the works, they were completed under the supervision of Mr. Chas. W. Merrin, his chief assistant, by whom the front was designed and the details of the building worked out. Mr. Crabb was the contractor. The parquet floor was laid by Mr. J. F. Ebner.

SALISBURY DIOCESAN CHURCH BUILDING ASSOCIATION.—A meeting of the general committee of this association was held in the Board-room, in the Close, on Tuesday week. An application was received and considered from the Rev. A. C. Burnard, Rector of Beer Hackett, in the archdeaconry of Dorset, asking whether his inability to complete the tower of the church in that parish would affect the grant of £50 made by the society towards the works which are being carried out. The committee resolved to deduct £5 from the grant, and to pay this sum when the tower is actually completed. In the case of Chicksgrove Tisbury, in the archdeaconry of Sarum, a certificate was handed in that the school-chapel there had been finished, and an order was made for the payment of the grant promised. An application was next considered for a grant towards the restoration of the parish church of Manningford Bruce, in the archdeaconry of Wilts, at an estimated cost of £1,500, the church, when completed, to seat 100 persons, all free, and a grant of £40 was voted. The remaining case was North Tidworth, in the archdeaconry of Sarum, the application being for a grant to take down and rebuild the present dilapidated church at an outlay of £1,350, only £784 of which has at present been raised. The church, when built, is to afford free accommodation for 130 persons, and a grant of £50 was promised.

SPALDING.—In March 1879, over 60 sets of competitive designs were received by the trustees of the Johnson Hospital, Spalding, when the one selected was that of Mr. G. G. Hoskins, F.R.I.B.A., of Darlington, (who has been so successful in other hospital works, already mentioned in our columns), shortly after which, the work was placed in the hands of Mr. James Bulling, of Ollerton, near Newark, and has been carried out under the supervision of Mr. Wallis, clerk of the works. On the 12th inst., the Hospital was formally opened by the Bishop of Lincoln. The aim of the architect was evidently, so far as externals were concerned, to present a building which, whilst in material construction corresponding with St. Peter's Church, to which it is adjacent, should at the same time bear upon the face of it evidence of its own all-important purpose; and, as to the interior, airiness, thorough ventilation, convenient ingress and egress, good lighting, and a favourable arrangement of aspects have all been carefully studied, and effected with the greatest possible success. The bricks used are of the same character and quality as those employed in St. Peter's Church; the eaves, cornice, and other work of a like description, are formed of purpose-made bricks; the sills, copings, and other dressings are of Ancaster stone, and the entrance steps of Park Spring stone. All the external walls are hollow. The front of the building faces to the eastward, and on passing into the main entrance the first room that presents itself to our right on the ground-floor is the operating-room. Next in order in the front of the building is the surgeons' sitting-room, from which only the main corridor has to be crossed in order to reach the consulting-room, and adjoining which is the surgery. Next in order comes the dispensary. The dispensary waiting-room is at the extreme north of the building, whilst to reach the dispensing-room and pass out, the

patients need but to pass along the main corridor, delay a moment at a hatchway provided for the purpose, and then make their exit by a door in the east wall. Along the main corridor to the south, we have porter's room, conveniently situated near to the main entrance. Next to this is the matron's sitting-room. To the west of these rooms, crossing the main corridor, is the convalescent and dining-room. Then comes the waiting-room for prospective in-patients, and at the extreme south the board-room. To the west of the main entrance there is also a complete set of kitchen offices. Ascending the main staircase, we find that all the wards are arranged on the first floor, occupying the extremenorth and south respectively. Provision is made for twenty patients—ten males and ten females. Adjoining all the wards are the nurses' rooms. In addition to these wards for general patients, a small room at either end of the building has been provided for isolated cases, or for the accommodation of patients who may require either exceptional quiet or unusual attention. Detached from the main building and approached by a covered way from the kitchen offices, are the laundry (with drying closet attached), wash-house, coal-house, tool-house, ash-pit, &c., underneath which is provided cellage, and within convenient distance of which are also placed a soft-water tank, the mortuary, and other minor offices.

STOKE NEWINGTON.—On Friday last the corner stone was laid of the enlargement of St. Faith's Church, Stoke Newington. This church, designed by the late Mr. Burges, is built in the Early English, 13th-century style, and was consecrated by the Bishop of London in 1873. At that time, however, only the tribune, choir, and part of the nave were erected, and the death of its chief promoter, Mr. Robert Brett, of Stoke Newington, in 1874, prevented any practical effort for its completion until the present time. The tribune and choir form a chancel of noble proportions, capable of accommodating 300 persons, and the south clerestory contains an excellent organ by Hill and Sons, completed in 1880. On the death of Mr. Burges, in the present year, Mr. James Brooks, of Stoke Newington, was appointed to carry out the original design and finish the church by adding the un-built portion of the nave, Mr. Brooks having offered his professional services gratuitously.

TRANMERE.—On Tuesday the new church of St. Luke, Lower Tranmere, was consecrated. The cost of the building will be £6,000 in all. The church consists of nave, chancel, and side aisles, with clerestory. It is designed in the Late Gothic or Perpendicular period, simply treated. Advantage has been taken of the great fall of the land by placing the vestries underneath the east end, the choir vestry being large enough to seat over 100 persons. The church will accommodate 720 persons. There are four entrances, that at the south-west corner having a porch. At the west end of the nave is erected a substantial half-timber bell-cote. The whole of the exterior is local stone, and a portion of the interior is faced with Runcorn stone. The benches are of pitch-pine, also the altar-rail and table, the pulpit and font being of stone. The builders' work has been carried out by Mr. Alexander Bleakley, of Birkenhead. The whole has been designed and carried out under the superintendence of Mr. G. E. Grayson, 31, James-street, Liverpool.

WICKWAR.—The restoration of the church of St. Thomas, Wickwar, which has been in progress during the last sixteen months, is now nearly completed. The church is a stone building in the Early English style. In 1829 it was new roofed, new pewed, and fresh paved at an expense of £700. The chancel was restored in 1856, and an organ was erected. The task of preparing plans for the restoration was entrusted to Mr. W. L. Bernard, architect, of Bristol, and there were two contractors to carry out the undertaking—Mr. Lovell, of Wickwar, who did the masonry, and Mr. Roach, of Charfield, the carpentry. It was found necessary to have a new north wall, and the other walls have been repaired and neatly pointed outside. The embattled tower at the west end, in which are hung six bells, has been also repaired. The wall on the south side of the chancel was taken down and rebuilt.

WIGGINTON.—On the 7th inst. the reopening of St. Bartholomew's Church took place after

restoration. The church will now accommodate 200 persons. The date of the church is about 1370. In restoration two old windows were opened out, one in the south side of the chancel and another in the south side of the western chapel, the latter having been filled with stained glass by Mr. Bell, of London, the subject being St. Bartholomew. The chancel arch has been enlarged, and is acoustically and otherwise a great gain. The organ also has been enlarged, and removed to the chancel, an arch having been opened out into the vestry, so as to form an organ chamber. The roofs of the chancel, nave, and vestry are all new, the timbers being too decayed to admit of restoration, and raised to the original pitch; that, however, of the western chapel has been simply restored. The total cost was £900. The architect is Mr. Withers, Adam-street, Adelphi, London, who is also architect for the Northchurch parish-church restoration, and the builder is Mr. Fincher, of Tring; Mr. Lingard, of Berkhamstead, being the mason engaged.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

LEEDS ARCHITECTURAL SOCIETY.—The following is the syllabus of papers for the session 1881-1882:—Nov. 10, president's address and annual report; Nov. 24, "Terra-cotta and Faience as Materials for Constructive and Decorative Application," by Mr. James Holroyd; Dec. —, distribution of prizes (date to be announced hereafter); Jan. 12, "Lighting by Electricity," by Mr. H. P. Holt, A.I.C.E.; Jan. 26, "The Bedford Park Estate, Turnham Green," by Mr. W. H. Thorp, Grad. R.I.B.A.; Feb. 9, "Church Restoration: What to Do and What to Avoid," by Mr. C. Hodgson Fowler, F.S.A., F.R.I.B.A., of Durham; Feb. 23, "A Real and Ideal Architect," by Mr. J. W. Connon, F.R.I.B.A.; March 9, "Polychromatic Decoration of Gothic Buildings," by Mr. G. A. Audsley, F.R.I.B.A., of Liverpool. Nomination of Officers: March 20, "Dutch Architecture," by Mr. R. Phené Spiers, F.R.I.B.A., lecturer on architecture at the Royal Academy, London. Election of officers: April 6, members' soirée.

COMPETITIONS.

BATTERSEA BATHS AND WASHHOUSES.—Competitive designs were received in the month of May last from six architects who had been selected by the Commissioners, and we are now informed that the latter have availed themselves of the services of Mr. Ebenezer Saunders, member of the Metropolitan Board of Works, who will report as to the merits of the respective designs.

BOLTON.—At a meeting of the Bolton sanitary committee, on Monday, the report of the Hospital sub-committee was read as follows: The sub-committee stated that in response to the advertisements for designs for the borough hospital eleven sets were received, bearing respectively the following mottoes or devices: "As you like it," "Bolton," Borough Arms (device), "Desideratum," "Health," "Octagon," "Progress," Red Cross (device), "Sanitas," "Viola," and "Well considered." Prior to the sub-committee's decision the designs of "Viola" were withdrawn, and after careful consideration of the respective merits of the other designs, the sub-committee came to the conclusion to recommend that, subject to the conditions of the competition, the first prize be awarded to "Desideratum," and the second prize to Borough Arms (device). The envelopes containing the names of the authors of the designs marked respectively "Desideratum" and Borough Arms, were opened, and it appeared therefrom that Mr. Marshall Robinson, 19, Acresfield, was the author of "Desideratum," and Mr. T. Haselden the author of the Borough Arms design. It was resolved that the author of "Desideratum" be requested to furnish the committee with proof that his design can be carried out for £4,000. The author of the first design wins the premium of £25, and that of the second the premium of £15 offered by the Corporation.

"OWEN JONES" PRIZES, 1881.—This competition was instituted in 1878 by the Council of the Society of Arts, as trustees of the sum of £400, presented to them by the Owen Jones

Memorial Committee, being the balance of the subscriptions to that fund, upon trust to expend the interest thereof in prizes to "Students of the school of art who, in annual competition, produce the best designs for household furniture, carpets, wall-papers, and hangings, damask, chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded on the results of the annual competition of the Science and Art Department. Six prizes were offered for competition in the present year, each prize consisting of a bound copy of Owen Jones's "Principles of Design" and a bronze medal. The following is a list of the successful candidates:—(1) Gideon Fidler, School of Art, Salisbury, design for carpet; (2) John Lamb, School of Art, Kidderminster, design for carpet; (3) Thomas Dutton, School of Art, Nottingham, design for lace; (4) Rose Phillips, School of Art, Northampton, design for wall-paper; (5) Robert Harris, School of Art, Salisbury, design for chintz; (6) W. J. Cluow, School of Art, Macclesfield.

CHIPS.

Indian-ink drawings that are to be coloured or washed over with tints should have a little bicarbonate of potash added to the ink. After the drawing has been exposed to light for an hour or so, the lines can be gone over without washing them up.

The parish-church of Holsworthy, Cornwall, is to be rebuilt. The church has been in process of reconstruction for some time, and an anonymous donor having offered £200 towards the restoration of the nave, the vicar and wardens have determined to appeal for additional funds, so as to complete the whole building. The cost is estimated at £2,000, and Mr. Wiffen is the architect.

The memorial-stone of new board schools for the Warley Union District was laid by the chairman on Oct. 3rd. The schools consist of boys, girls, and infant department with the necessary classrooms, lavatories, residence, outbuildings, playgrounds, &c. Mr. R. F. Mathews, of Paradise-street, Birmingham, is the architect, and Messrs. Stockton and Son, of Oldbury, have the contract, £1,831, for the whole of the works.

New schools are about to be erected in the Bearwood-road, Smethwick, from the designs of Messrs. J. P. Sharp and Co., Birmingham, architects to the Harborne School Board.

A meeting was held at Haverfordwest last week to consider the desirability of restoring St. Mary's, the chief and finest church in Pembrokeshire, when it was decided to take steps to procure subscriptions with that object.

Serious and repeated complaints having been made as to the quality of the water supplied to the city of Ely, the Local Government Board have instructed their inspector, Mr. S. J. Smith, to hold a local inquiry into the matter on Friday, the 28th inst.

New corn-stores have been erected at Oldbury for Mr. H. T. Nock. The contract for the works, £1,450, has been executed by Messrs. Stockton and Son, contractors, of Oldbury. Mr. W. Withers, of New-street, Birmingham, was the architect.

The local board of Brentford, at their meeting on Tuesday week, adopted the plans of Messrs. Gotto and Beasley, civil engineers, of Westminster, for the drainage of the district, subject to certain modifications suggested by Captain Gilton and the approval of the Local Government Board. The estimated cost of the scheme is £18,000, but this will be considerably increased by the proposed alterations.

Messrs. Robert Boyle and Son have recently applied their complete system of ventilation and sanitation to the Brompton Oratory, South Kensington, which has proved highly successful, the Rev. Fathers having presented Messrs. Boyle with a valuable testimonial to that effect. The new extensions to the Devonshire Hospital, Buxton, opened last week by His Grace the Duke of Devonshire, are also fitted throughout with Messrs. Boyle's air-pump ventilators, which are at present being applied for the ventilation of Lambeth Infirmary.

Messrs. Chambers, Munery, and Co., of 41, Bishopsgate-street Without, are introducing some remarkably cheap and well-designed office-fenders (made also as curb for tiled hearths) worth the attention of our readers.

A new vicarage has just been completed for St. Michael's Church, Trivale. The architects were Messrs. Davis and Middleton, of Birmingham and Dudley, and the contract for the works, amounting to £1,337, has been carried out by Messrs. Stockton and Son, Oldbury.

"To a practical man with a taste for mechanics, and the bumps of conscientiousness fairly well developed, we can give no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *Engineering*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mousetrap, to the latest method of calculating the phases of Orion!—The *Brighton*. Price Two-pence of all newsmen, or post free 2½d.—St. Tavisstock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31 TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. FASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All *Situation advertisements must be prepaid.*

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.
Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete Vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—C. E. J.—M. and Co.—J. D. M.—G. and Co.—J. P. M.—F. C. Co.—B. A. B.—C. D. and Co.—E. G. O.—J. L. A.—H. F. H.—W. H. S. and S. D.—J. A. and Son.—T. H. Co.—C. D. and Co.—B. P. H. Co.—T. S.—J. C. B.—W. F.—H. L. S.

J. A. SAUNDERS, Folkestone. (The only mode of obtaining Prof. Roger Smith's lectures at University College is by attending the courses, as the College authorities do not allow class lectures to be published.)

MEDICAL SEALS.—ERRATA.—In our issue of last week the numbering of figures on the plate was transposed. For "1" read "5," for "2" read "1," for "3" read "6," for "5" read "3," for "6" read "8," for "8" read "2." In the letter press on p. 486, col. 3, line 13, for "Renulf" read "Kenulf"; p. 486, col. 3, line 14, for "is the finest" read "is of the finest"; p. 487, col. 1, line 24, for "Wariogay" read "Worm-gay"; p. 487, col. 2, lines 6 and 7, for "Figs. 2 and 3" read "Figs. 5 and 6."

Correspondence.

"FREE PROFESSIONAL SERVICES."

To the Editor of the BUILDING NEWS.

SIR,—The letter of Mr. J. L. Robinson, in your issue of this week, with your editorial note,* that we should be allowed to correct the paragraph referred to, has rather taken me by surprise.

As senior of our firm, I beg to state that the reason we have offered our services gratuitously is that it is a national movement, which has met not only with universal approval, but has drawn forth large subscriptions from all classes of the community.

We are not alone in thus helping a good cause. An eminent firm of solicitors in this city have done the same, and I do not for a moment believe the rules of the Institute would forbid any architect making such an offer.—I am, &c.,
H. P. N. DEANE, F.R.I.B.A.

* The postscript referred to was not an "Editorial note."—Ed. "B.N."

SIR,—We have a saying, at this side of St. George's Channel, "that if you put an Irishman on a spit, you could get another to roast him." I hope you won't think that I am turning the spit, in referring to what seems to be a case of "kettle and pot," appearing under the above heading in your last issue, and "Our Office Table" in the number for the 16th ult., as I suppose it is the same Mr. John L. Robinson who figures in both.

In one, it is stated that "he had prepared plans for a new Town-hall in Cork, but the mayor said the designs would cost nothing, as he sent them unsolicited and free of charge," but you charitably add that he received an official vote of thanks for his very admirable sketch. In the other case he incloses a statement that Messrs. Deane and Sons wrote to the Committee of the National Exhibition of 1882, intimating their willingness to give their gratuitous professional services to the Committee, which were accepted with thanks.

The difference between the two cases appears pretty much like, "twee-dle-dum," and "twee-dle-dee," unless it lies in *submitting plans and offering services*, or that they were rejected in one case and accepted in the other, in both "with thanks"; or perhaps being a Fellow of the R.I.B.A. makes the custom of architects offering their gratuitous services more honoured in the breach than in the observance.

As Mr. Robinson thinks it fair to give the firm he refers to an opportunity of correcting errors, and is ready with his pen, as to others, perhaps he would set himself right in the matter, or in the words of the once-popular song, "Correct those failings in himself that he condemns so in another."

Limerick, Oct. 15, 1881.

M. M.

SIR,—Your correspondent, Mr. Robinson, should not fret about the doings of the firm whose name he gives. Offering "gratuitous services" is merely a bid for popularity, and a means of keeping before the public, for the services of Messrs. Deane and Sons will not be required by the Committee of the Irish Exhibition. Mr. Edward Guinness has given the use of the existing building free for twelve months—a fact of which Deane and Sons were aware. If any alterations are required, doubtless Mr. Guinness will have them made under the supervision of his own architect. A piece of practice on the part of the same firm, which seems to have escaped Mr. Robinson's notice, was the sending in (without being asked by the authorities to do so) a set of plans some time ago, for the new art buildings to be erected here, and for which a competition is now open. There is nothing like having a good eye to business.—I am, &c.,
Dublin, Oct. 17, 1881. SIMPLE SIMON.

SIR,—Mr. Robinson writes with real Irish emphasis. Boycotting will be, I expect, his next suggestion! Why should not the gentlemen he refers to give their services? They have as much right to do so as others to charge five per cent. I expect there are very few gentlemen in the profession who have not at some time or in some way given their services. Friend R. surely disquieteth himself in vain. No great harm will ever be done in this way; the practice will assuredly be very circumscribed.—I am, &c.,
M.

THE "SATURDAY REVIEW" AND FREEMASONRY.

SIR,—I have read both the article on page 439, and the letter of "Knight Templar," on page 503; but although the latter proves the writer has a warm heart to the "Order," the historical knowledge he shows is scarcely so creditable to him. If he had read much about the history of Freemasonry he would have known that many students of history have asserted that what has been known for the last century and a half as Freemasonry, "was invented and established in, or about, 1717." The fact that Freemasons adopted old masonic signs, tools, and emblems is no proof that Freemasonry itself is old, and I hardly think Woodford and Whytehead are the most reliable Freemasonic writers. W. J. Hughan in England, Findel in Germany, and D. Murray Lyon in Scotland, are all authors of higher repute; the latter is the Grand Secretary for Scotland, and both he and Hughan—an Officer in the Grand Lodge of England—coincide in

asserting that there was no Freemasonic system of three degrees in existence until about 1717, nor any Grand Master until the same year. Then a good while after that—viz., towards the end of last century, Masonic Knights Templars, and other high-sounding degrees sprang up. The adoption of a similarity in nomenclature does not involve historical or hereditary relationship. VERITAS.

FOREIGN TRAVELLING STUDENTS.

SIR,—Although foreign travel is so universally recognised as an essential part in the education of an architect, there does not appear to be any regular route laid down, and every one contemplating an architectural tour is left pretty much to his own devices to find out in which towns the various buildings best suited to his purpose are to be found.

I think it would not be a very difficult matter for some competent persons to make out such a route, and if a little extra trouble were taken, a list might be made of places and buildings that would be of the utmost value not only to those who (1) intend to travel, but also to those who, (2) being unable to go abroad, study at home, in that it would give a definite idea at a glance of the history of architecture. The list that we need is one something like the following, arranged under such headings as:

Country	Town.	Building.	Date of Comm.	Date of Compl.	Style.
					Earliest example in Greece.
Greece.	Corinth.	Temple.	655, B.C.	581, B.C.	of Doric in Greece.

And commencing thus, going on through Italy, France and England, down to the time of the Revolution. The list to contain only those buildings in which each successive step (as nearly as it can be done) in the history of architecture can be traced. With regard to the secondary object proposed, it might be well to go back a great deal further in dates, but it would not be necessary as far as travellers are concerned.

The BUILDING NEWS, being a journal which most students of architecture take in, would be a fitting place for the publication of such a list, if anyone could be prevailed upon to compile one for us, and if you could afford the space for it in your columns.—I am, &c.,

R. W. B.

HOUSE DRAINAGE AND SEWER AND GULLY VENTILATION.

SIR,—From the letter of Mr. Buchan on this subject, page 508, he has evidently misunderstood some of my remarks upon sewer ventilation. I did not suggest the use of the rain-water pipes as a means of ventilation. I think if Mr. B. will read my letter again, he will see it was quite the reverse: "The sewage drains would be the only ones having a direct communication with the street sewer." I should not advocate the use of rain-water pipes as a means of ventilation for the same reasons as stated by Mr. Buchan.

As a rule, however, rain-water pipes on the front side are generally connected direct with the street sewer, without being intercepted by a gully-trap, or any regard being shown as to the inlet from the caves gutter being adjacent to bedroom windows.

In reference to the escape of sewer-gas from the street gullies after a continuance of hot dry weather; although the surface area of the gully exposed to the atmosphere might be reduced, and the depth of the water-seal increased, evaporation would still go on, and the contents which remain would be mere sludge.

I think a system which would dispense with the necessity of a trap in the street gully is the best method to adopt. I am, &c.,

Juta, Oct. 18, 1881.

W. B.

MR. P. J. DAVIES ON WATER-TRAPS AND SIPHONS.

SIR,—In reference to the traps, Figs. 93 and 94, on p. 421, I should like to ask Mr. Davies if he can point to any published drawing prior to A.D. 1875, showing these in the same way as he has drawn them, especially at the turn-down point B in each? Or is this the improvement that he refers to on page 421? I have imagined that I was the first to definitely point out, in 1875, the improved effect produced in the well of a trap by causing the water to fall over a sharp edge in place of over a rounded edge; but if any other party published that before me, then *Palmarum qui meruit ferat*—but upon satisfactory evidence.

In regard to the quotation from Pliny, given by Mr. Davies on p. 421, it, of itself, hardly shows reference to the use of water siphon-traps to keep back the air on the outer side of the trap from getting into the pipe on the inner side of the trap. It simply shows that Pliny knew that water would rise to its level even through a pipe with ups and downs in it. I would infer, however, that he must also have known that to enable it to do so in a close or air-tight pipe, the air requires to be let off at the higher part of the bend before the water can flow onwards, unless where the pressure is so great as to force the air before it.

Coming, next, to p. 456, may I ask why Fig. 100 is shown "upside down"? Does that mean that the way it is drawn is not really the way in which it has been applied, and that it is "shown upside down" to make it more like Fig. 101? Fig. 100, as drawn, and Fig. 101 have this advantage over Fig. 99, that if the water runs out of the trap from any cause the ball still acts, or tends to act, as a barrier to the passage inwards of the air beyond the trap; whereas, in Fig. 99, should there get a hole, by frost or otherwise, in the trap to let out the water, then the foul air blows directly into the house, the ball B, in Fig. 99, being quite useless in such a case, and the same may be said of the Bower trap, Fig. 102.

Further on, p. 492—Jenning's ball-trap, Fig. 103, which Mr. Davies says "is simply perfection," and "requires no criticism as to merits or demerits," is, in my opinion, quite open to criticism, and, although a very ingenious and clever trap, is open to the imperfection of being apparently all right, when in reality it may be useless. It has the same fault as pointed out above with Figs. 99 and 102, viz., that the ball is only a mere supplementary addition to the water, and not independent of it. Should a hole get into the metal of the part where the water lies, as during frost, then the water may run off and the foul air blow freely in; B then being only a dummy, or sham sentinel. Then, again, should a sand-hole exist in the inside metal above the ball, and the sand by-and-by get washed out or corrosion occur, then the trap becomes useless, so that altogether for safety Fig. 103 is much inferior to Fig. 101, although so much neater-looking than the latter.

W. P. BUCHAN.

Intercommunication.

QUESTIONS.

[6729.]—**Dairy and Poultry Farm Buildings.**—Can any reader recommend a good book with designs for, or a description of, such structures? Also for pigeries.—P. PLAYFAIR.

[6730.]—**Asbestos.**—I wish to warm a room by means of asbestos fuel. Will any of your readers kindly inform me if I must use an atmospheric burner, or will an ordinary burner be suitable? Also, what is the probable cost per hour?—A. SUESCABBA.

[6731.]—**Old Crosses in West of Cornwall.**—Is there any authentic list of existing granite crosses in this interesting part of England? I met with many curious examples during a hasty visit to the neighbourhood this summer.—H. DUNSFIELD.

[6732.]—**Down-Draught in Chimneys.**—I have lately entered a new house, and find every chimney acts as a conductor of air into the rooms, strong down-draughts. Can any of your readers give me advice as to the best way of remedying this great evil?—W. B.

[6733.]—**South Africa.**—I am a joiner, and am anxious to emigrate to South Africa. Are there not some labour agencies who send out mechanics? Some reader will, perhaps, give information in "Intercommunication."—JACK PLASE.

[6734.]—**Rain-Water.**—I have somewhere seen an invention described by which the rain-water, as it runs off the roof after a shower, is discharged into a waste pipe, but by an automatic balancing arrangement the water, as soon as clear, is diverted to another pipe, so that it may be conducted to a rain water tank. Can any contributor give me particulars of the foregoing, and where it may be obtained?—B. S.

[6735.]—**Rain-Water.**—The following circumstance has come under my notice, viz., a rain-water tank has been recently constructed in some premises in the South of England of 9in. brickwork in cement, finished with 3in. cement plastering, coated with Russian tallow. It is about 15ft. deep, and 6ft. diameter, covered with dome and ordinary manhole (originally intended for cesspool). Has an overflow pipe. Rain-water is conveyed from slated roofs by means of ordinary cast-iron eaves, gutters, and down pipes, and stoneware drainpipes jointed with clay and cement. Very little if any surface water is admitted. The water is drawn from tank by means of ordinary iron lift-pump and iron pipe. The water used for culinary purposes is supplied by a company, and is obtained from the chalk, and is very hard. The rain-water, instead of being soft as usual, is as hard as the water supplied by the company. What can be the reason?—J. E.

[6736.]—**Calculating Deals.**—Will some reader of the BUILDING NEWS kindly inform me the most practical and correct way of reducing deals, battens, &c., into standards by fully illustrating the same, so that I may thoroughly understand the rule? What is the meaning of the following:—210.21 × 7 white battens at containing 3:1.2646. 1+1 the 1 of a standard? What is the meaning of 26 2/3?—SAM THOMAS.

[6737.]—**Pull on Casting.**—A casting, A B C, as shown in the diagram, working on a cone at A, and

loaded with 20lb. at C. What would be the horizontal pull at B, the weight of the casting not being taken into consideration?—SEVENAX.

REPLIES.

[6653.]—**Variation of Compass.**—"L. L. U.," on p. 511, took rather a rough way of determining the variation. You cannot do it accurately unless sufficiently acquainted with astronomy to determine in what part of its orbit the Polar star is at the time of observation, because, although practically stationary for general purposes, it really has a 2° or 3° orbit, which of course affects any angle of variation that may be obtained. I took the variation by theodolite some years ago in Bengal when on survey duty, and made it, if I remember rightly, 3° 8' when the correct amount was about 2° 47'. In Morayshire, in 1863, it was 23° 30' West, which may help "L. L. U." in obtaining the present amount there.—P. PLAYFAIR.

[6657.]—**Chimney Shaft.**—Hugh McLachlan is, of course, correct in saying, on p. 511, that drawings would have to be submitted to the district surveyor. One knows that. What is inquired for is the data upon or by which the surveyor is supposed to check designs.—P. PLAYFAIR.

[6694.]—**Deductions in Brickwork.**—What does "Young Surveyor" mean by "quoins having copings"? Does he intend copings of gables, &c., when of stones cut with horizontal beds and vertical sides for bedding on to the brickwork, to be so understood, if not, would he please explain? The following extract from the system recommended by the Manchester Society of Architects may help him, published in BUILDING NEWS, April 10, 1874. "To obviate any misunderstanding as to so-called trade usages, with regard to other materials, as stone, &c., built in, it is proposed to measure the nett quantity of brickwork to be executed; deducting entirely all labour and materials in openings having more than 100 square feet 'face' measure, and deducting materials only (leaving 'hollows' for labour) on the following:—All other openings than the above, the shape they are actually executed, provided they are openings in the walls and built above with the same materials. All cills, strings, cornices, &c., and other masonry or dressings built in, and being more than six inches high. The 'hollows' thereon being assumed to pay for the labour in providing proper bed therefore, filling up thereto, and pointing up." The above is from the trade of "Brick setter," the last clause appears to be what is required. I do not understand the term "hollows," perhaps it is of local use only.—H. McLACHLAN.

[6692.]—**Statics and Dynamics.**—The work recommended by the Royal Institute of British Architects to students for their examinations is Todhunter's "Mechanics for Beginners." I have no acquaintance with it, but the name of the author is a sure guarantee of the quality of the work, and it is to be hoped for those who are not versed in mathematics that it does not prove many of the theories thereby. I have studied what I know of the subject from Cassell's "Popular Educator" and Tomlinson's "Elementary Mechanics" (Weale's Series), the latter is a little antiquated, but its truths are still the same; in both these the subject is treated in a simple manner, arithmetic only being used in the theory of mathematics. If "W. S." knows hardly anything of physics he would do well to read Balfour Stewart's Shilling Primer on "Physics" published by Macmillan and Co. For a more advanced work I would recommend buying some work published by the last-named publishers, and the intending student would do well to glance through it before purchasing to see whether it is above his level or not. The best works often use algebra and trigonometry in their explanations, as with Rankine's and Parkinson's.—H. McLACHLAN.

[6692.]—**Statics and Dynamics.**—A very good treatise, and one I can recommend to a beginner, is Baker's "Elementary Statics and Dynamics," published in Lockwood's series, about 18. 6d. A more advanced treatise is Twiss's "Practical Mechanics."—G. H. G.

[6693.]—**House Surveying.**—My experience in surveying has led me to think the surveyor who is instructed to examine house property and old buildings, cannot go too well equipped with such things as spirit-levels and plumb lines. Such tests are not usual unless a very elaborate survey has to be made upon the condition of a building, but they are very necessary. No practical surveyor should be without the two former of these instruments mentioned, and a gimlet is almost as necessary to test the condition of timbers. A mere superficial examination of joists, rafters, and plate is often very misleading, as the interior may be perfectly rotten, and a few thrusts with a pointed pen-knife will not give so good an idea of the soundness of a large scantling as a gimlet-hole. There is nothing *infra dig.* for an architect or surveyor to carry with him the necessary instruments for his professional avocations, no more than for a surgeon or physician to carry a case of probes or lancets or a stetho-

scope in his pocket. In surveys for sanitary purposes, as in the examination of drainage and ventilation, a set of tools and instruments for measuring the velocity of flow and the currents of air in shafts become necessary. I know of no books on the subject.—G. H. G.

[6993].—**House Surveying.**—I expect surveying for dilapidations is referred to, I know of no work as required. A spirit-level is useful to test the levels of floors, &c., and a plumb line to test the upright of walls and chimney-stacks. The eye is generally sufficient for the purpose, but the named instruments show exactly the degree of settlement. I expect the "gimlet at the end of a walking stick" was used to find whether there was any dry rot, but if that existed strongly the stick alone would have been quite sufficient. When within reach a penknife is sufficient if the blade be pushed into the wood; dry rot is often hidden by an outer shell about one-eighth of an inch thick or less.—H. McLACHLAN.

[6995].—**Plastering.**—Cracks arise sometimes from settlement and sometimes from shrinkage in the laths. The lime is also at fault if not properly slaked, and the stuff is best kept.—G. H. G.

[6995].—**Plastering.**—Probably from the "rendering" coat not being sufficiently keyed to the laths, or not beaten well between them to form a key on the upper side. Theoretically I should say the "rent laths" are much better, for their inequalities and knot holes are first-rate for the purpose of keying, which is of more importance than an equal thickness of stuff, even though the latter will cause some cracking from unequal shrinkage. It is really impossible to have plaster-work without cracks; these will always be caused by shrinkage on the drying out of the water, and though these may be filled up, the elasticity of a wooden floor is sure again to cause others. The different causes mentioned in question will all occasion cracks to a greater or lesser degree.—HUGH McLACHLAN.

[6996].—**Cement Work.**—I should think that the rendering coat had become too dry before the finishing one was laid over it. To remedy some knock off all unsound work, back and notch well into rendering coat, and well wet same by sprinkling with a plasterer's brush before laying on the finish. Cracks will be likely to appear at junction of old and new work after drying, if so these can be stopped afterwards.—HUGH McLACHLAN.

[6998].—**Factor of Safety.**—It would be well if querists would study the elements of building before entering into the "intercommunication" column of the BUILDING NEWS, it would save themselves and others much trouble; for if they mean to study the subject, the elements must be learnt, and the sooner it is done from observation and books the better; it will also at times save them from unpleasant remarks. I intend to give over answering questions when the information desired can be learnt from nearly every person acquainted with the subject, therefore in future answers on such questions are not to be expected from me. All materials break under pressures or strains if these are increased or produced to a sufficient extent. These pressures and strains are chiefly:—compression, tension, cross breaking which subjects the piece submitted thereto to both compression and tension at the same time in its separate parts, torsion and shearing. Compression is simply crushing and tension is pulling asunder; the other three will be found I believe in all cases to be these two united in different manners. Torsion is the strain caused by twisting, and shearing is a breaking asunder caused by one part of the material being forced in one direction and another part being forced in an opposite direction, making, as it were, the one part to slide over the other. Experiments have been tried on various materials to see what pressures and strains would destroy them, the pieces being made of similar sections and the pressure or strain measured in lbs. or tons, generally reduced to a mean on sections of one inch square; the mean results for similar materials of similar and same sized sections are called constants, and it is from these that the breaking weights and desired dimensions are calculated. Before the breaking point is reached, fracture is generally noticed to commence, and this is called the point of fracture. It is also found that in bodies submitted to cross strains and torsion that a small part in each is under no strain, this part in each is called the neutral line. Further from the experiments it has been found that the breaking weights vary considerably, this of course arises from defects in the materials operated upon, for instance, knots and shakes in timber, air bubbles and sand holes in iron and veins and cracks in stone and brick, also other inequalities. Now it being well known that no piece of any material can be perfect and also that a large number of the defects in the materials can not be discovered, it is necessary to allow a large margin for safety; and as the point of rupture is only a fraction by measure of the breaking weight, say one-half or one third, and still more that the limit of elasticity is even less, for if a body is subjected to a strain beyond its limit of elasticity it will not recover the same perfectly and therefore for future use is not so strong, for these reasons it is necessary to use only a small fraction of the breaking weight as the extreme load or strain to which the piece should be submitted, and this fraction is called the *factor of safety*. It varies with the material and also with the kind of strain and by different authors is variously given the same being the case regarding *compression*. The factor of safety under a tensile strain for wrought iron is taken as one-fourth, for a cross strain as one-sixth and for a compressive strain as one-tenth; for other materials which are not so well understood and more uneven in texture, one-tenth is generally taken. I might have added that the *limit of elasticity* is that point reached when any body is bent and cannot recover exactly its former position. "M." and others equally ignorant should read B. Stewart's Primer on "Physics" referred to in my answer No. 6992.—H. McLACHLAN.

[6999].—**Oil in Boards.**—What I believe to be the best remedy is very simple. Lay brown paper over the parts injured and then apply a hot iron, this will draw out the oil, which will then be absorbed by the paper. I expect that these parts will always appear darker than those uninjured.—H. McLACHLAN.

[6999].—**Books.**—Send to R. T. Batsford, Holborn, London, W.C., for catalogue of architectural books.—H. McLACHLAN.

[6991].—**Books.**—"Subscriber" may consult Scott Burn's works on "Farm Architecture. For specifications, the best work is Donaldson's "Handbook of Specifications," and a smaller treatise, containing a good model specification, is Wrightwick's "Hints to Young Architects," edited by G. H. Guillaume. A good provincial pricebook was noticed last week in the BUILDING NEWS, compiled by R. Beckett. For surveying and levelling I recommend Simm's and Baker's treatises. All these books may be obtained of Messrs. Lockwood and Co., Stationers' Hall-court.—G. H. G.

[6992].—**Lunatic Asylums.**—I believe no work has been published on this subject. "Esquire" would however learn much by studying a paper read at the Architectural Association on "Hospitals for the Insane" and reported in full. Dr. Oppert also refers to them in his work on hospitals.—H. McLACHLAN.

[6995].—**Brick Architecture.**—The introduction of Dobson's "Bricks and Tiles" (Weale's Series), gives a short list of old buildings. Mr. Tavenor Perry's paper "on the Mediaeval Brickwork of Pomerania" read at the Royal Institute of British Architects, Nov. 17, 1873, and James Brown's "Brick Ornament and its Application" advertised on the front page of the BUILDING NEWS. "S. F. C." will see many of the best examples in London, in the Temple, Lincoln's Inn, and pretty generally through the West Central District and Chelsea. Nearly all the seventeenth and eighteenth century buildings within twenty miles of London when not of stone may be inspected. Rotterdam, Amsterdam, Bruges, and other towns of the Netherlands are rich in this respect. The best new work is also to be found as a rule in the neighbourhood of the best old work.—HUGH McLACHLAN.

[6997].—**Softening Putty.**—In answer to "A Subscriber," I find in Mr. Fawke's book on "Horticultural Buildings," published by Batsford, p. 103, the following:—"When ordinary putty becomes very hard it may be softened for the purpose of easy removal by keeping it moist for a short time with caustic potash or soda, or if the putty be painted, with nitric or muriatic acid, it will be softened in about an hour." Instructions are also given in the same book on page 102 for making putty, which will not be liable to get hard, crack, and allow water and frost to get in.—N. G. T.

[6998].—**Plumbers' Solder and Smudge.**—"A Young Plumber" may get some hints as to these upon pages 19 and 20 of Buchanan's "Plumbing," No. 191 of Weale's Series.—AS OLD PLUMBER.

[6999].—**Rainfall, Sewage, &c.**—Latham's work on "Sanitary Engineering and the Statistics," published by Mr. Simons, will give all that is needed. These subjects will also be found fully treated in the back volumes of the BUILDING NEWS.—G. H. G.

[6993].—**Shoring.**—I know of no work treating of underpinning and shoring, except in a very casual manner. The dangers likely to occur from want of shoring are generally apparent enough to those who have charge of a building. With respect to the principles of shoring, they are simple, and an acquaintance with the elements of mechanics is all that is required. The forms of shores are well known, and will be found in Hurst's edition of "Tredgold's Carpentry" (Spoe and Co.). It would be useless to lay down any principles without knowing the exact case "W. G. M." has in view. One general principle of some importance is to relieve by upright posts and crosspieces or needles any weight which is acting injuriously in any direction, and then to give the lateral support. Thus, if a house wall leans it is desirable to relieve the loads on the upper floors by propping between the floors, removing the load as far as possible, and after this has been done to place the raking struts. The chief danger of underpinning arises from defective bond and bad mortar. If the wall is at all shaky or "rotten," it is not safe to underpin more than 2 or 3 feet at a time, and this should not be done without relieving the wall of any weight that it may have to sustain at this part, and every care ought to be used to find out if the wall carries the weight of any other structure than its own load.—G. H. G.

[6994].—**Gas-Tar and Shingle Paths.**—Remove all soft soil and fill in 6 or 8 in. deep with stones, broken bricks, &c., which would pass through a 2½ to 3 in. ring. After levelling and consolidating, put a layer of smaller stones about 3 in. thick, which would pass through a 1 in. or 1½ in. ring level, and then cover with layer of levelled gravel. Heat the gas tar, and to boiling condition ladle it out on the gravel. Old waterpots without the rose will be handy. Dust over upon the distributed tar fine gravel. When sufficiently set, and as soon as possible, roll with heavy garden roller. In hot weather some work done in this manner was rolled a day or two after being laid, but the whole did not set firmly for two or three weeks; then it was satisfactory. I should think fine granite chips, Derbyshire spar or crushed shells would form a better appearance if sprinkled on the hot tar instead of gravel.—F. T.

[6997].—**Mounting Drawings.**—One method I have frequently adopted has answered well. It is as follows:—The stretcher being naked, i.e., no calico strained on it, apply the selvage edge of the calico to the edge (not front nor back), and nail it on with tacks about 2 in. apart, then the opposite side, stretching the calico very tightly, with tacks about 6 in. apart, then one of the other sides, not stretching so tightly as for the last, with tacks about 6 in. apart, and then the opposite side, stretching very tightly. Fill in the tacking on the three sides, making the tacks about 2 in. apart, stretching the calico very tightly before driving each tack. Cut off the superfluous calico when it is ready for mounting the drawing. Paste on strips of coloured paper, covering the tacks. Cut the drawing to leave a margin on stretcher of the width desired. Lay the drawing face downwards, and cover the back with paste rubbed on with the hands, carefully covering every part, avoiding lumps and an uneven thickness of paste. Pay special attention to the edges. Damp the calico with a moist sponge. Place two corners of one side of drawing on the stretcher, another person holding the opposite corners well up. Place a large sheet of clean paper over the side just attached, and gently and quickly press down the sheet, the assistant yielding to the pressure. Each person rub down on the piece of clean paper with a scale or set square, and work out the superfluous

paste at the edges. Clean off with damp sponge. Starch some prefer to paste.—F. T.

[6993].—**Separate Cistern to W.C.**—It seems to me that "O." has not sufficiently stated his case. To keep the service pipe "charged" he must have a stool cock at the bottom. If within the district served by the New River Company, the w.c. will have to be fitted with a waste preventer. For a stool cock to be regulated by waste preventer fixed at the top of the "charged pipe," it would necessitate a complication liable to get out of order in a short time. If waste preventer was fixed in connection with the stool cock at the bottom of the pipe, judging from those that I have seen from their beautiful and delicate construction, it would cease to act with the least particle of grit, and I don't believe this would pass the company. The water in the cistern feeding w.c. with a "charged pipe" is subject to the minimum of contamination, but "O." must bear in mind that an open sink and a w.c. pan are not on a par for comparison, as he imagines.—N. D. F.

[6993].—**Separate Cistern to W.C.**—The objection to a w.c. being flushed direct from a storage tank arises from the fact that, even with a valve under w.c. seat, the flush pipe is liable at any time to become a vent pipe, but when a service box or valve in cistern is used, the danger is greatly increased, because there is at all times a direct communication between the w.c. pan and the tank, up which the foul gases are constantly passing and being absorbed in the drinking water. If any one doubt this he may easily convince himself by holding his nose over such a pipe while the w.c. below is being used.—DANIEL EMBAGE.

[6995].—**Girder.**—If "H. D." refers to any of the one thousand and one books on strains, he will find correct diagrams showing tension and compression.—P. PLAYFAIR.

LEGAL INTELLIGENCE.

IN RE JOSEPH WOODHOUSE.—Before Mr. Registrar Ilazlitt.—The debtor, carrying on the business of a builder at Tottenham and Kingsland, presented his petition for liquidation a few weeks since, estimating his debts at about £15,000, and assets £12,000. The meeting of creditors having been recently held and adjourned, Mr. Doria applied on Monday for a further injunction restraining several actions. His honour granted the application.

STAINED GLASS.

WARMINSTER.—A stained-glass window, the work of Mr. Charles Evans, of Fleet-street, London, has lately been erected in the Chapel of St. Boniface Mission, Warminster. The subject represented is the "Crucifixion"; the figures of St. John and the B. V. Mary are introduced at either side, the whole being surmounted with an ornamental canopy and base.

NORWICH.—In connection with the restoration of St. Peter Mancroft Church, a window in the south-east portion of chancel has been filled with stained glass by Messrs. Clayton and Bell. The cost was £400, and the work is a memorial of the late Mr. Robert Seaman. It contains full length representations of SS. Peter, John, Paul, and Barnabas, and there are also the following scenes:—In the centre "The Call of Peter," "The Charge to Peter," "The Stoning of Stephen," "The Martyr of Antioch," and "Paul Preaching at Athens." On the right-hand side is Barnabas introducing Saul to the Apostles, and the "Healing of the Cripple at Lystra." On the left-hand side are the Apostle John leading the Virgin Mary home from Calvary, and the same apostle at Patmos. Beneath the window is an inscription.

CHIPS.

The church of St. Emanuel, Lockwood, Huddersfield, has just undergone considerable improvements, including the erection of a very handsomely-carved memorial oak pulpit, in the Decorated style, with the top of open tracery work, filled in with brass grilles. An ornamental reredos is also among the work, which has been executed by the firm of Messrs. Jones and Willis, of Birmingham and London.

Hereford Cathedral school was founded by Bishop Gilbert, in the year 1331. This, the 500th anniversary, has been appropriately celebrated by commencing the erection of a school library in memory of the founder. In addition to the library, two new classrooms are being added; and arrangements are being made for isolating boys in case of illness. The works are being carried out from the designs of Mr. Kempson, F.R.I.B.A., and the contractor engaged is Mr. Callis, of Hereford. The works will all be completed before speech-day comes round again.

The Chiswick improvement commissioners inspected on Thursday se'night the additional tanks and precipitating works at the pumping station, which have just been carried out under the superintendence and from the plans of Mr. H. O. Smith, C.E., their surveyor. The tanks are four in number, measure 94ft. by 40ft., and are constructed in concrete, with brick facings. The contractor was Mr. Harry Smith, and his foreman, Mr. Standen.

Our Office Table.

THE report of the select committee appointed to consider the working of the Artisans' and Labourers' Dwellings Improvement Act, 1875, and the amending Act of 1879, has been issued. It states that, owing to the lateness of the session, all the witnesses were not examined, and the report therefore recommends that the Committee should be reappointed early next session. It is, however, suggested that, with the view of lessening the expense of carrying out the Act of 1875, the confirming authority might well consent to the basement and ground-floor of any building being let as shops or workshops, and that in considering the amount of accommodation to be provided for the working classes displaced by any scheme, the confirming authority would be justified in giving a liberal interpretation to the relaxing power in the 4th section of the amending Act, and might take into account, as in part fulfilment of the obligation to provide equally-convenient accommodation, any suitable existing facilities of transport, to a reasonable distance and at reasonable prices, by water, tramways, or workmen's trains.

RAPHAEL MONTI died in London on Sunday, aged 63. A native of Milan, he studied sculpture under his father, Gaetano Monti, and at an early age won the Gold Medal of the Imperial Academy in that city by a group of "Alexander taming Bucephalus." His next considerable work, "Ajax defending the body of Patroclus," was exhibited before he was grown up. Between 1838 and 1842 he resided at Vienna, and between 1842 and 1847 was occupied with several groups designed to add to the attractions of Milan. In the last-mentioned year he came to England, where his "veiled statue," executed at the instance of the Duke of Devonshire, elicited high praise. Returning soon afterwards to Milan, he gave in his adherence to the popular party, and in 1848, as one of the chiefs of the National Guard, was sent on a mission to the camp of Charles Albert. The war over, he again came to England, and from that time devoted himself to his art.

AN Educational and General Art Exhibition is to be opened at Stirling early in the ensuing year. It is proposed to obtain and exhibit works from Art Students and Art Schools both in England and Scotland; and from promises which have already been received, it is expected that the present exhibition will afford an interesting and instructive illustration of the progress of Art-Education throughout the country. It is intended to add a general exhibition of original works of art by professional and amateur artists. The exhibits will include (1) Paintings in oil and water-colour, (2) paintings on china, terra-cotta, or other pottery ware, and (3) studies in black and white—including original architectural designs. The exhibition will be opened in the galleries of the Smith Institute as soon after the 1st January, 1882, as arrangements will permit. Intending contributors are requested to communicate with the manager before Thursday, the 22nd December, 1881. All works sent, through the agents, for the exhibition must be delivered to them as follows:—London agent, Mr. James Bourlet, 17, Nassau-street, Middlesex Hospital, London, till about the 15th December; Messrs. Doig, McKechnie, and Davies, Edinburgh, till about the 19th December; Mr. Geo. Davidson, Glasgow, till about the 19th December.

BOROUGH surveyors and sanitary officials serve too many masters to grow bumptious, or many might feel taken down an inch or two after reading the following anecdote of the late Mr. A. W. Morant, engineer to the borough of Leeds, contributed by Mr. J. T. Bottle to a memoir just printed for private circulation by Mr. Wyatt Papworth, while Mr. Morant lived at Great Yarmouth. An aggressive-looking female, with a plethoric umbrella, came one day stumping into the surveyor's office at the Town Hall, and fixing on Morant her glittering eye, she asked, in the most uncompromising tones, "Are you the man what belongs to the gutters?" A bright smile arose on his face, and the patient way in which he entered into the small sanitary grievance, addressed to him in a tone which might have been considered insulting to a scavenger, was never forgotten by the listener. When the visitor had departed Mr. Bottle and his friend

had a hearty laugh, and Morant exclaimed, "If ever I feel bumptious with respect to my official position (which he certainly never did), I shall try and recollect that, after all, I am, in the view of the public, only 'the man that belongs to the gutters.'"

THE new session of the Royal Institute of British Architects will be opened on Monday fortnight, the 7th of November, by an address from the president, Mr. G. E. Street, R.A., and the meetings will be held fortnightly after that date, the first for the reading of papers being arranged to take place on the 21st prox. It is announced that no applications (under the old rules) for the associateship of the R.I.B.A. will be received after the 31st December next.

THE opening conversazione of the Architectural Association will be held on Friday in next week, the 28th inst., at the Conduit-street Galleries, when an address will be delivered by the new president, Mr. Aston Webb. The following is a list of the gentlemen who have consented to read papers, with the titles and dates of delivery, so far as they have been definitely fixed:—Nov. 23, "The new Examination, and what it involves," Professor T. Roger Smith; Dec. 9, "Barnacles," Mr. Cele A. Adams; "Physical Science in relation to Architecture," Mr. J. Slater; "Specifications," Mr. Ewan Christian; "Some Thoughts on Principles of Design in Church Architecture," Mr. B. E. Ferrey (who has recently reversed his initials); "Sundry Working Drawings," Mr. J. P. Seddon; "Ideal Dwelling Houses," Mr. E. Ingress Bell; "The Influence of Ritual on Church Architecture," Mr. E. Eldon Deane; papers by Messrs. G. Aitchison, A.R.A., and John Hebb; "Architectural Inconsistencies," Mr. P. E. Masey.

THE Prince and Princess of Wales on Tuesday opened the new East Dock at Swansea, which has been constructed at a cost of about £300,000. The new dock nearly doubles the dock accommodation of the port, and was commenced in 1879. The harbour now consists of a South Dock, 13 acres, with a half-tide basin of five acres, communicating with each other by a lock 300ft. long, furnished with three pairs of gates 60ft. wide, and having entrance-gates 70ft. in width. The North Dock covers 14 acres, with a half-tide basin of 2½ acres, connected with the dock by a lock 100ft. long and 65ft. wide, having at its seaward-end entrance-gates 60ft. wide, and at its northern end smaller locks communicating with the Swansea Canal and the upper part of the river Tawe. The North and South Docks have 23ft. of water over the sill at ordinary spring tides, but the new East Dock have a far greater depth, besides being in various ways better adapted for large vessels. The area of water that will be enclosed in the new dock is 23 acres, which will give a length of 2,320ft., a breadth varying from 500ft. to 340ft., and a depth of 36ft. The outer sill of the dock will have on it 32ft. of water at ordinary spring tides. The work has been designed and carried out from plans by Mr. James Abernethy, President of the Institution of Civil Engineers, and the contractor was Mr. Walker, of London.

CANDIDATES FOR THE GODWIN

BURSARY (value £40), open to all members of the profession of British Architects, are required to send in their applications and testimonials on or before 30th JANUARY, 1882, not later than 4 p.m., to the undersigned, in accordance with the Schedule of Regulations (copies of which may be obtained at the office of the Institute). Carriage and all expenses must be paid by the Candidate.

J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM B. WHITE, Secretary.
Royal Institute of British Architects, 9, Conduit-street,
Banover-square, London, W.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY.—St. Paul's Ecclesiological Society. "Roman Antiquities Discovered in Warwick-lane, E.C." By W. J. Adams. 7.30 p.m.
FRIDAY.—Architectural Association. Opening conversazione. 8 p.m.

A new church is about to be built close to the Brentford abutment of Kew-bridge, from the plans and designs of Mr. A. W. Blomfield M.A., of London.

The prizes were presented to the successful students in the Merthyr science and art schools on Thursday week, by Mr. C. H. James, M.P., who congratulated the meeting on the favourable character of the report, and the good work carried on in the school.

Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Only in Packets labelled—JAMES EPPS & CO., Homoeopathic Chemists, London."—*Mak* 'rs of Epps's Chocolate Essence for afternoon use.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, BILIOUSNESS, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the M-sker, 113, Holborn Hill. Use no substitute. See Medical Testimony.

Holloway's Ointment and Pills.—All ulcerations, sores, abscesses, bad legs, and skin diseases are best treated by these medicaments. The ointment eradicates all noxious taints, and makes every symptom assume a milder form, and this desirable result is made doubly certain by the purifying, regulating, and alterative powers of the Pills.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to **CHARLES TRASK**, Norton-sub-Hamdon, Ilminster, Somerset. —[Advrt.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates. General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country. —[Advrt.]

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.
PICTOR & SONS, BOX, WILTS.
(See trade advt. on p. XXV.) Advrt.

TENDERS.

*Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ALLOA, N.B.—For construction of the Alloa and Forth Bridge Railway:—
Watt and Wilson, Glasgow (accepted).

ARBRATH—For the erection of a manse at Arbroath, for the Abbey Church Congregation. Messrs. J. MacLaren and Son, Dundee, architects:—

Mason's work:—			
Alexander, Arbroath	£579	9 6
Mitchell, Arbroath	553	0 0
Caldor Bros., Arbroath	548	10 0
M'Laren and Nairn, Arbroath	548	0 0
Fife, Arbroath	526	0 0
Ram-ay and Gordon	499	0 0
Anderson, Arbroath (accepted)	496	10 0
Joiner's work:—			
Dathie, Arbroath	331	0 0
Scott, Arbroath	306	0 0
Watt, Carnoustie	304	4 9
Farquhar, Arbroath (accepted)	298	10 0
Gasfitter's and plumber's work:—			
Dyer, Arbroath	91	10 0
Tyne, Arbroath	88	12 9
Rayne, Arbroath	88	0 0
Burnett and Fletcher, Arbroath	84	10 0
Brown, Dundee	83	10 0
Burness, Arbroath	82	19 5
Farquharson, Dundee (accepted)	78	0 0
Plasterer's work:—			
Campbell, Arbroath (accepted)	50	0 0
Gibson, Broughty Ferry	46	0 0
Slater's work:—			
Mit-hell, Arbroath	34	15 0
Burnet, Arbroath (accepted)	33	13 0
Gauld and Laburn, Dundee	30	19 0
Blinds:—			
Westwood, Sons and Miller, Dundee*	...	11	7 6
Bells:—			
Westwood, Sons and Miller, Dundee*	...	8	11 6
*Accepted.			

ASHOVER.—For the erection of a new school at Ashover Upper-end, for the Ashover Charity Trustees. Mr. W. Bramham, Clay Cross, Derbyshire, architect. Quantities by the architect:—

Askew, W. B. Matlock	£586	13 0
Adams, R. Middleton	544	0 0
Mellor and Askew, Littlemoor	540	17 0
Hopkinson, Reed, Milltown	509	16 9
Walker, J. and Sons, Wirksworth	499	18 0
Beardlow, T. J., Ashover (accepted)	492	17 9
Redwood & Wass, Sutton-in-Ashfield	397	0 0

BAMBER BANGOR.—For erection of a police-station, court-house, and out-buildings, for the Walton-le-Dale District at Bamber Bridge, near Preston. Mr. T. Nevett, Winckley-street, Preston, architect:—
Walmesley, J., Preston (accepted).

BATH.—For erection of a boys' school in rear of Dove-
place, Walcot, Bath, for the School Board. Mr. C. B.
Olive, 39, Great James-street, Bedford-row, W.C.,
architect:—

Hatherly, W. and T., Bristol	£1,857	0	0
Bladwell, Bath	1,795	0	0
Birch, Bath	1,710	0	0
Cross, Bath	1,680	0	0
Hayward and Wooster, Bath	1,627	0	0
Hewlett, Bathurst	1,490	0	0
Morris and Son, Bath	1,488	0	0
Mould, C. and W., Bath	1,470	0	0
Mann, R.	1,467	0	0
Emery, Bath	1,460	0	0
Morgan and Lovell, Bath	1,460	0	0
Chancellor, Tiverton	1,450	15	0
Long, T., Bath	1,389	0	0
Gay, E., Bath (accepted)	1,321	0	0

BRIGHTON.—For alterations and additions at No. 39,
Middle-street, Brighton, for Mr. C. C. T. Mr. S. Den-
man, architect:—

Cheesman	£80	0	0
Parsons	82	10	0
Newham	802	0	0
Patching	790	0	0
Dean	770	0	0
Garrett	755	0	0
Wright (accepted)	594	0	0

BRIGHTON.—For construction, &c., of the new roof
(containing 3,500 tons of iron), for the Brighton
station:—

Patent Shaft and Axletree Co., Wednesbury (accepted).
BROMLEY, KENT.—For erection of Plaistow Vicarage,
Bromley, for the Rev. W. Hodgson. Mr. W. R. Millett,
architect:—

Arnold	£3,139	0	0
Grubb	2,908	0	0
Mitchell	2,800	0	0
Crossley	2,845	0	0
Scrivener	2,763	0	0
Payne	2,667	0	0
Balding (accepted)	2,575	0	0

BROMLEY, KENT.—For house connections with main
sewer:—

Lansbury, T., Bromley (accepted).
[Other tenders received from Peill and Sons, Bromley;
Hill, Brothers, Beckenham; Woodham Brothers,
Penge; J. W. Neave, Lewisham; G. Stephenson, Dart-
ford.]

BUCKINGHAM.—For repairing the workhouse boundary-
walls:—

Smith, G., Buckingham (accepted) ... £8 17 0

CHELTENHAM.—For building a villa residence in the
Queen's-road, Cheltenham. Mr. Place, Regent-street
Chambers, Cheltenham, architect:—

Clarke, T., builder, &c., Grosvenor-street, Cheltenham
(accepted).

CLAPHAM, S.W.—For alterations, &c., to 113, 120, and
122, High-street, Clapham. Mr. Johnson, architect.
Quantities by Messrs. Northcroft, Son, and Neigh-
bour:—

Tafman and Potheringham	£2,650	0	0
Lawrie Brothers	1,990	0	0
Hall	1,928	0	0
Earl and Son	1,893	0	0
Hobson	1,873	0	0
McLachlan and Sons	1,813	0	0
Maxwell	1,745	0	0
Mills	1,700	0	0
Sawyer	1,677	0	0
Lane and Son	1,634	0	0
Thorne	1,549	0	0

COCKERMOUTH, CUMBERLAND.—For alterations and ad-
ditions to premises in Main-street, Cockermouth:—

Joiners:—			
Crone, T., Cockermouth	£83	10	0
Moore and Swain, Cockermouth	55	0	0
Dent, H., Cockermouth (two late)	55	0	0
Robinson, P., Cockermouth	51	10	0

Joiner and carpenter:—
Reay, T., Cockermouth (accepted) ... 53 13 6

Builders:—			
Bolton, J., Cockermouth	56	0	0
Althouson, J., Cockermouth	25	0	0

Mason's work:—
Gidson, J. and W., Cockermouth* ... 35 10 0
*Accepted.

CROYDON.—For making-up and repair of various
roads, for the local board of health:—

Cornwall-road, Theobald's-road, Westfield-road, Vic-
tory-place, Back-road, and Child's lane:—
Lake (accepted).

Lawrence-road and Canby-road:—
Etheridge (accepted).

Hastings-road:—
Streeter (accepted).

Nicholson-road:—
Lundridge (accepted).

DUBLIN.—For heating the infirmary portion of the
workhouse at Abbeygrove, also the dining-hall and chapel,
with hot-water, for the Dublin Board of Guardians:—

Boss and Murray, Dublin	£169	0	0
McGuire and Co., Dublin	156	11	0
Gibbs, R. R., Liverpool	150	0	0
Power and Son, Kilkenny (accepted)	148	0	0
Dobbs, R., Abbeygrove	145	0	0
Brooks, Thomas and Co., Dublin	102	13	6

ELV.—For scavenging the city, for the local board of
health:—

Lupton ... £300 year.
Rickwood ... 200
[Neither tender accepted, the board having decided to
have work carried out under their surveyor.]

GREATWORTH.—For repairing and other works at St.
Peter's Church, Greatworth, near Banbury. Mr. H. H.
Gough, F.R.I.B.A., architect:—
Cottrill, Culworth (accepted) ... £312 9 0

GLASGOW.—For pile-driving and other work required
to strengthen a portion of the General Terminus Quay
wall in Glasgow Harbour, about 855ft. long, for the
Clyde Navigation Trustees. Mr. G. Keith, general
manager:—

Morrison and Mason, Glasgow (accepted).

[Other tenders received from D. Maxwell, Glasgow;
J. and T. Maxwell, Pollokshields; J. Bain, Boness;
Glen and Dobbs, Kilsyth; Muir and Girdwood, Mother-
well; J. Buchanan, Glasgow; A. Coghill and Co., Glas-
gow; A. Edie, Glasgow.]

GREAT MARLOW.—For erecting a new school and class-
room at Sir Wm. Borlase's school. Mr. C. Carter,
architect:—

Corby, A.	£450	0	0
Carter, R. G.	420	0	0
Carter, J. S. (accepted)	416	0	0

(The two rooms will afford accommodation for from 90
to 100 boys.)

HALIFAX.—For erection of two dwelling-houses in
Lindwell, near Greetland, Halifax:—

Accepted tenders.
Mason:—Taylor, G., Lindwell, Greetland.
Joiner:—Taylor, J., Lindwell, Greetland.
Plasterer:—Wadsworth, T., Lindwell, Greetland.

HOLDEN.—For the construction of new sewers in John-
street, Little James-street, and St. John-street, within
the Holborn district. Mr. Lewis H. Isaacs, Assoc. Inst.
C.E., surveyor:—

Wilkes and Co.	£1,794	0	0
Crockett	1,586	0	0
Marshall	1,577	0	0
Mowlem, J. and Co.	1,450	0	0
Pord and Everett	1,422	0	0
Neave and Son	1,394	0	0
Killingback (accepted)	1,350	0	0

HOMERTON, E.—For painting, &c., at Homerton Works
house, for the Hackney Union. Messrs. Lee and Smith,
architects:—

Jolley and Callen	£2,839	0	0
Pope	2,510	0	0
Goldman	2,522	0	0
Martin and Goddard	1,906	0	0
Shurmer	1,853	0	0
Everhard	1,829	0	0
Barber, Son, and Co.	1,820	0	0
Gentry	1,765	0	0
Roberts	1,634	0	0
Flaxman	1,490	0	0
Wells and Co.	1,297	0	0
How	1,296	0	0
Burman	1,242	0	0
Barker and Co.	1,239	0	0
Williams	1,195	0	0
Stevenson, S.	1,137	0	0
Macarty	815	0	0

HONTOX.—For alterations and additions at No. 148,
Hoxton-street, for Mr. R. Hillier. Mr. Edward Brown,
18, Finsbury-street, Spitalfields, architect:—

Marr, R.	£119	0	0
Skipper, G.	369	0	0
Salt, S.	360	0	0

HUDDESFIELD.—For proposed new chancel, vestries,
&c., to St. Mark's Church, Longwood, Huddersfield.
Quantities supplied by the architect, Mr. J. W. Cockings,
New-street, Huddersfield:—

Mason:—			
Hill, J.	£640	0	0
Grubham, B. and N.	620	0	0
Schoff-11 Bros.*	614	0	0
Bates, S.	580	0	0
Ephraim, D.	579	0	0
Royston and Sons	572	10	0

Joiner:—			
Christie, J.	132	10	0
Garmory, S.	132	0	0
Batey, J.	125	0	0
Balmforth, I.	122	10	0
Wool Bros.	118	10	0
Shaw, W. H.	112	0	0
Walker, J.	99	10	0

Plumber:—			
Brook and North	48	12	0
Mellor and Crowther	47	0	0
Garton, G.	45	15	0

Plasterer:—			
Tunncliffe and Sons	47	10	0
Jowett, W. E.	43	3	0
Morton and Sons	40	10	0
Bottomley, E.	35	0	0

Painter:—			
Stuttard, J. H.	16	0	0
Bottomley, E.	15	0	0
Earnshaw Bros.**	15	0	0
Holroyd, W. and P.	13	10	0
Preston, J.	13	0	0

Stainer:—			
Jowett, W. E.	50	8	0
Pycock and Son	50	0	0
Goodwin and Sons	46	0	0
Alison, T.	38	17	6

* Accepted at £594; + at £110 10s; + £15 15s;
+ plastering, £22; + concrete, £13; ** £15; +, £38
17s. 6d.

HUDDESFIELD.—For erection of a washhouse and
laundry and alterations to present kitchen, at the Deans-
house Workhouse, for the Huddersfield Guardians.
Messrs. J. Kirk and Sons, Huddersfield, architects:—

Masons:—			
Moorhouse and Pogson, Meltham.			
Joiners:—			
Kaye, J., and Son, Holey More.			
Plasterer:—			
Quarmby, J., Holmthorpe.			
Slaters:—			
Pycock, W., and Sons, Leeds.			

ISLINGTON, W.—For building a masonry at Dockwell
Hospital, for the Heston and Isleworth local board:—
Daneels, of Hounslow (accepted) ... £31 10 0

KENSINGTON.—For two houses, South Kensington.
Messrs. George and Peo, architects. Quantities by
Messrs. Stonor and Sons:—

Simpson	£15,540	0	0
Williams and Son	15,125	0	0
Colls and Sons	14,558	0	0
Brass	14,371	0	0
Ashby Brothers	14,147	0	0
McLachlan and Sons	13,940	0	0
Manley	13,050	0	0
Stevens	12,768	0	0

LANDPORT (HANTS).—For extension of Conway-street
Board School, Landport, for the Portsmouth School
Board. Mr. G. Rake, Ordnance-row, Portsea, archi-
tect:—

Bevis, Portsmouth	£2,357	4	6
Burbridge, G., Southampton	2,139	0	0
Light, Landport	2,117	0	0
Lewis, W. D., Southampton	2,096	11	6
Earwaker, R., Southampton	2,066	0	0
Cooper, T. C., Portsmouth	2,010	0	0
Quick, T. W., Southampton	1,975	0	0
Evans, Southampton	1,953	0	0
Crook, J., Southampton	1,897	0	0
Beech, G., Southampton	1,777	0	0
White, F., Landport (accepted)	1,754	0	0

LEIGH (NEAR WORCESTER).—For execution of drainage
works within the Leigh Special Drainage District. Mr.
E. Pritchard, C.E., engineer:—

G. Law, Kidderminster, (accepted), according to sche-
dule of prices.

LIMPHOE, NORFOLK.—For building tower to St. Bar-
tholomew's Church, Limphoe. Mr. Arthur S. Hewitt,
A.R.I.B.A., 8, Regent-street, Yarmouth, architect:—
Hawes, G. C., Norwich (accepted).

LLANRO.—For proposed new shop at Llanrug, Carna-
von, North Wales, for Mr. G. Roberts. Mr. J. P. Mun-
ford, architect:—

Williams, J.	£2,180	0	0
Price, P.	2,160	0	0
Williams, G.	2,158	0	0
Edwards, H.	2,140	0	0
Williams, G. H. (accepted)	2,100	0	0
Roberts, J.	1,903	0	0
Owen, W.	1,745	0	0

LONDON.—For two houses, Harrington-road, for Mr.
W. Cassell, Esq. Messrs. Ernest, George, and Peto, ar-
chitects. Quantities supplied by Messrs. Stonor and
Sons:—

Simpson and Son	£15,540	0	0
Williams and Son	15,125	0	0
Colls and Son	14,558	0	0
Brass	14,371	0	0
Ashby Bros.	14,147	0	0
McLachlan	13,940	0	0
Manley	13,050	0	0
Stevens and Bastow, Bristol	12,768	0	0

LOXLEY.—For three shops adjoining the Greyhound,
Lea Bridge-road. Mr. Cotton, architect:—

Handley	£2,483	0	0
Hewlett	2,378	0	0
Tomms	2,285	0	0
Shurmer	2,187	0	0
Hayworth	2,039	0	0
Jackson and Todd	1,819	0	0
Edwards	1,480	0	0
Young, W.	1,198	0	0

LOXLEY.—For extension of premises, West Ferry-road.
Mr. Eve, architect:—

Borke	£1,873	0	0
Nightingale	1,772	0	0
Crabb	1,764	0	0
Morter	1,759	0	0
Niblett	1,750	0	0
Hall, Biddall, and Co.	1,719	0	0
Abraham	1,697	0	0
Macey and Son	1,616	0	0
Lawrence	1,579	0	0
Harris and Warlop	1,574	0	0
Crisp and Toulton	1,517	0	0
Shurmer	1,485	0	0
Salt	1,472	0	0

LOXLEY, W.—For sundry works at No. 7, Great Port-
land-street. Mr. R. Reid, architect:—

Ebbs and Sons	£288	10	0
Hatfield and Son	258	0	0
Foxley	218	0	0

LOXLEY (NOTTS).—For erection of lecture hall,
classrooms, &c., at Long Eaton. Mr. A. H. Goddall,
Market-street, Nottingham, architect:—

Cooper, Nottingham	£1,271	0	0
Wheatley & Mauls, Nottingham	1,165	0	0
Fullalove, Long Eaton	1,147	0	0
Starr, Beeston	1,147	0	0
Youngman, Long Eaton	1,097	0	0
Morrison, Nottingham	1,067	0	0
Budd, Beeston	1,021	0	0
Clepham, Norwell (accepted)	1,018	0	0

NEW CHILWELL, NOTTS.—For 1,248 yards of 9in. pipe
sewers at New Chilwell, near Nottingham for the
Shardlow Sanitary Authority. Mr. Joseph Bullock, sur-
veyor:—

Cope, J., Nidley	£216	0	0
Thombs, W., Steinon	197	0	0
Tomlinson, J. and G., Derby	177	0	0
Knight, J., Loughton	177	0	0
Hughes, H., Lower Gormal	157	10	0
Beardsley and Pounder, Ilkerton	145	15	7
Todd, G. F., Derby (accepted)	137	18	4
Parsons, G., M. nfield	130	0	0
Hawley, T., Ilkerton	125	0	0

THE BUILDING NEWS.

LONDON, FRIDAY, OCTOBER 28, 1881.

FORMS OF CONTRACT.

WE have, on a former occasion, spoken of some of the legal requirements of contracts, and we now mean to refer to a few of the clauses which generally appear in the conditions prefixed to specifications. These are usually of a rather vague kind, and not much relied upon; though if contractors fully understood and realised the full meaning of some of the clauses to which they put their signatures, they would be more circumspect and cautious before undertaking work. There is generally a clause at the commencement of these conditions which states that the drawings and specification must be taken together according to their true intent and meaning, and it has been decided in several instances that the omission of certain necessities from the specification was not sufficient to entitle the builder to charge them as extras, they being implied in the general terms. If, for instance, the flooring of a room be omitted, or not particularly described in the specification, yet the same may be reasonably and obviously inferred from that document and the drawings. How far, however, a Court will hold a contractor to provide certain things which are not so obviously inferred from either one or the other of these documents, it is hard to say, and it is therefore necessary to add the sentence "that in case of any discrepancy between the drawings and the specification, the architect is to decide which is to be followed." It is very common for a contractor to turn round and say that a thing is not specified, and that he must be allowed an "extra" for performing it, but few who do so can realise fully the meaning of the clause we have cited. Another clause usually found in conditions relates to the supply of copies of the drawings and specification. It runs usually in this form: "Complete copies of the drawings and specifications, signed by the architect, are to be furnished by him, or by the measuring surveyor, to the contractors for their own use, and the same, or copies thereof, are to be kept on the buildings in charge of a competent foreman, who is to be constantly kept on the ground by the contractor, and to whom instructions can be given by the architect." In important works this clause is fully carried into effect; the architect supplies tracings of all drawings and details, or they are supplied by the surveyor who takes out the quantities, who goes over and examines the figured dimensions, carefully checking them with those he has used for the measurement of the work. In smaller contracts the labour generally falls on the architect, and it is very necessary to make this set of tracings correct copies of the contract drawings. We have occasionally seen very rough tracings in the hands of contractors, in which sectional parts, mouldings, and other details were slurred over in a very ship-shod fashion, as if anything would suffice; in some cases it is evident these rough tracings have been prepared by the contractor himself or the clerk of works in great haste. In some contracts it is customary to insert a clause to the effect that figured dimensions are to be taken in preference to those shown by scale, and it is very common to find discrepancies, which have escaped the notice of architect, builder, and quantity surveyor, becoming serious causes of disagreement and unpleasantness. In many otherwise good forms of contracts, no reference is made

to errors in figuring or scale, and the result is that the builder claims for additional brickwork, flooring, and other items; hence these discrepancies are discovered in setting out the building on the ground, and entail often extras for excavation and concrete, besides walling. Increased depth of footings as they occur should be booked by the clerk of works, and the additional depth marked on the plans. A great deal of after-trouble might be saved by anticipating these contingencies and providing a clause to meet them in the contract, thus a set form of clauses, useful as they must always be, seem to call for modification in nearly every case.

One of the most important provisions is that referring to alterations and variations in the work, and the clauses which are generally inserted to meet these are worded in various ways. As the form that has been settled between the Council of the R.I.B.A. and the Committee of the London Builders' Society may be taken as a well-discussed clause, we quote it here. It runs: "No extra work is to be executed except upon the express order of the architect, to be shown by any instruction or subsequent approval in writing, or by any drawing, plan, or account signed or initialed by him. Provided always that if the architect shall require the contractors to execute any works as a variation which he may decline to order as an extra, the contractors may reserve the question of their right to be paid for the same until the final settlement of accounts. No charge for day-work is to be allowed as such, unless the authority for the work shall expressly direct it to be done as day-work, or unless the work cannot from its character be reasonably valued by measurement. All vouchers for day-work are to be delivered to the architect within 14 days following the week in which the work may have been executed. Any variation made in carrying out the works is not to vitiate the contract, but unless a price or schedule of prices be previously agreed on, the value of all variations is to be ascertained by measurement or otherwise. All omitted works are to be deducted at prices not exceeding those contained in the estimate on which the contract was based, and all additional works are to be valued at fair measure and value prices, the value so ascertained to be added to or deducted from the amount of the contract." These terms fairly meet all the general requirements of architects and contractors. They give the contractor power to reserve any question touching a variation without causing interruption of the work, and the subject of day-work is clearly laid down. In cases where a schedule of prices is not accepted or a price is not agreed on, any addition is to be arrived at by measurement and valuation. Omitted work is to be valued at the prices of the contractors' estimate. Occasionally modifications may be introduced to meet exceptional cases, but the above terms include most of those kinds of deviations which occur in practice. It is only reasonable that an architect or his employer may be able to vary within certain limits without necessarily incurring expense, yet in the larger part of contract agreements the terms are so equivocally expressed, that a variation is looked upon as an extra.

It is unnecessary to quote in full other clauses, such as that giving the architect power to remove from the premises all materials not in accordance with the specification, and alternative power to employ other persons to remove the same; also to pull down or substitute work or materials that he may condemn. In such a clause, however, the contractor should be allowed a right of reference, and the terms adopted in the form of conditions we have quoted provides for it. The words "notwithstanding any certificate for payment which may have been given," ought to be affixed

to the provision we have mentioned, as where this has not been done we have known a contractor uselessly plead the certificate which he has lately received as a justification of defective workmanship or material which the architect has discovered some time afterwards. The value of work inefficiently done, or not according to the conditions, can be deducted from the contract price, and the employer can set up this defence to any action brought for the whole sum; in fact, the law does not entitle the builder to any remuneration for badly-executed work. A very necessary and safe clause in the interest of the employer is that which states "that all work or material forming or intended to form part of the building are to be considered to be the property of the employer," though, on the other hand, he is not to be made responsible for any loss or damage in respect of such work or material, the contractors having complete charge of the works, and being responsible for watching the same. The clause defining the time of completion should be explicit, and yet not unnecessarily severe on the contractors, and we think it right and just that alterations made, and "strikes and lock-outs" in any of the trades should qualify the time of completion. The terms of this clause are not strictly, or indeed often, enforced, yet the wording should be such as to leave no doubt on the mind of the contractor, and to make him feel that justice will be done him should stress of weather or any unforeseen accident occur. Another very necessary provision ought to refer to defective workmanship or materials being discovered within a reasonable time after the completion of the building, making the contractor answerable for amendment, the amount in case of dispute being settled by arbitration. The amounts of certificates, reserving sums for papering, painting, &c., to be paid on completion, depend so much on circumstances, that it would be of little use to adopt any particular form. A certificate of the architect, as we have said before, is conclusive evidence of the completion of the works, and entitles the contractors to immediate payment, though it may be necessary to add to the clause introduced into the contract the words, "without prejudice to the liability of the contractors to amend and make good defects within a reasonable time." Another condition generally relates to contingencies such as the bankruptcy of the contractor, reserving power for the employer or the architect to enter and take possession of the works and to employ other persons to complete them at the cost of contractors. It is only fair to add a clause in case of the bankruptcy of the employer, to enable the contractors to suspend the works and to require payment for all materials wrought and works executed, &c. Insurance of building in an approved office, and a clause at the end providing for questions in dispute or difference, as to additions or other matters, ought always to be introduced, and the forms adopted in the conditions we have mentioned appear reasonable and fair. Such arbitration clause should apply to every matter arising under or out of the contract except under those clauses in which the architect is mentioned as being the sole arbiter. A frequent cause of difference arises from an architect withholding or otherwise altering the certificates, and it appears to be only just and proper that such difference may be referred, without any suit at law, to an arbitrator agreed on by both parties, or to two arbitrators, one to be named on each side, with power to employ an umpire, the costs of which reference to be in the hands of the latter. A good form of contract will vary its terms to meet the circumstances of each case, and builders will be found more ready to contract under conditions which have been prepared to suit the wants of the work than they would to

bind themselves to a number of arbitrary rules which seldom meet the case, and are on this account unheeded. Architects would also be more satisfied if they thoroughly understood the conditions under which they were acting, which in many cases they do not, having probably never practically tested the forms they daily use, not from intelligent conviction, but from habit.

BUILDING IN SOUTHWARK.

SOUTHWARK, one of the most densely-populated portions of the Metropolis, has lately shown a few signs of progress. Not long ago we had to chronicle the demolition of one of the old and noted hostels, and more recently of that grim, walled-in area, known as the Queen's Bench prison, both sites which have since been covered by new buildings. The Queen's Bench prison was a solidly-built brick group of buildings, inclosed by a high brick wall with massive buttresses, familiar to all who have travelled through the Borough from the Elephant and Castle over London Bridge. The appearance of the old prison was extremely dismal, and the sight of the huge dark walls exercised a depressing influence on those who lived under their shadow. These buildings have been swept away, and the old boundary-wall, 3ft. thick at the base, and battering to about 18in. at the top, has been pulled down, except a small part. The prison was massively built of brick, and one or two of the smaller buildings still standing for temporary use retain traces of some excellent workmanship. The most important erection which has been made in Southwark of late consists of two extensive rows of blocks of industrial dwellings on this site, commenced about two years ago by Mr. J. W. Hobbs, as a private speculation, but which has lately been acquired by the Directors of the National Model Dwellings Company. These dwellings, called "Queen's Buildings," are, without exception, the largest group of buildings that have been recently erected in London for the purpose, and consist of several immense blocks, comprising accommodation for 150 families, each dwelling containing a suite of two or three rooms, self-contained, and separated from the others in the same group. To be more precise, each floor comprises a two-room and a three-room dwelling, access to which is by a stone staircase, common to each block of five stories. Each dwelling is provided with a sink, copper, range, dust-shoot, and w.c.; the rooms are of good size, and furnished as completely as houses of a superior rent. The lower stories are finished as shops, which face the Scovell-road, opposite the rows or blocks. The rents range from 6s. 6d. to 10s. 6d. per week.

In the planning and construction of these comparatively immense ranges of dwellings we find convenience, economy of space, and substantiality have been the chief objects of the builder. The situation is undoubtedly one of the best which could have been selected. These buildings are within an easy distance from the large warehouses and wharves on the Surrey side of the Thames, and within a mile of the City, not far from the Elephant and Castle, Blackfriars, and close to the Borough-road-stations of the London, Chatham and Dover Railway; the tenants who occupy them are in a very central position in regard to the chief centres of work. The two parallel rows of blocks already built abut at the west-end on Southwark-bridge-road, and on the east on the main route to London-bridge, to which latter they are at right angles. A new road called Scovell-road is thus formed between. On the south side the buildings are bounded by Borough-road. Another series of blocks, forming a third parallel row, are about to be erected

on the north side facing Collinson-street, and these have a series of cross or lateral blocks behind abutting on the back of the present rows, so that the greatest advantage is taken of the area. From what we have said, there are ten sets of dwellings in a block between each pair of party-walls, comprising in all twenty-five rooms, without including the shops and basements. These blocks are over 30ft. frontage each, and one row contains nine of them. The depth from front to back is 35ft., the entrances and staircases to the dwellings just completed are in the rear, and are placed centrally. On each side we find, on entering, a kitchen or living-room, fitted with one of Doulton's stoneware sinks, a copper (Smeaton's patent), a dresser, coal-bunker, a dust-shoot, forming a projection on the outside, and a w.c., also projecting and entered from a small balcony. Fronting the roadway are the bedrooms. Cupboards are provided in each room, and the woodwork is grained and varnished. The closets are fitted with Tylor's apparatus. We also find the ventilation of the dwellings has been attended to; the soil-pipes are carried up, and each is open at the top; the closets, forms a projection on each side of the open stairs from top to bottom, and have external windows; the windows of the rooms have sashes, but no special mode of ventilation other than the fireplace flue and the windows has been introduced. The roofs form flats, and are constructed of joists, 9in. by 3in., with concrete filling in, and covered by Seyssel asphalt. No special provision to render the dwellings fireproof has been attempted. The floors are of wooden joists, but substantial, and the staircases and landings have been constructed of stone, and rest upon solid walls, so that one great risk is minimised.

In the architectural treatment of these dwellings there is little to call for remark. White perforated bricks have been used in the fronts, with malm gauged arches neatly executed, in some cases springing from stone skewbacks, or relieved by lintels and labels of stone. The windows are varied in their dressings; the centre windows of each block slightly break forward, and have stone jamb-shafts, skewbacks and labels; the others have stone lintels and arches of brick. There is a stone corbel-table with a series of arches below the cornice, with trusses at the piers; and the elevations finish with a panelled brick parapet, the straightness of which is broken at intervals by ball terminals over the piers. Between the blocks, marking their division, are narrow brick pilasters springing from carved corbels, and horizontal members or stringcourses break the otherwise vast brick fronts. It is difficult, indeed, to treat in an architectural manner immense rows of dwellings where economical considerations have the first regard. Given a front and back wall, with a repetition of internal arrangements of precisely the same kind, it is impossible to do more than to vary the windows or employ slight brick or stone relief. More might, we think, have been done with the staircases; but these occupy the rear of each row, and the designer was left to make the best of a long lofty façade of brick with nothing but windows of bedrooms and shops below. In these circumstances the architect is restricted; to give light and shadow, calls for breaks and recesses, and to vary the roof line, gables and expensive roofing are entailed—both out of the question. Lightness, without conforming to any style, appears to have been aimed at, and the fresh new fronts, with their neatly-finished windows and black tuck-pointed joints, are at least unpretending. The backs, with the closet and dust-shoot projections, are perfectly plain, only relieved by red-brick arches, and by the small balconies on each

floor which give access from the living-rooms to the closets and dust-hoppers. The acute angle at which the ends of the rows are cut off by the Borough-road, made it difficult to obtain a pleasing front to the road. At the other end a coffee-tavern has been built, called the Queen's Bench Tavern, at which tenants and others may get good refreshments of a non-alcoholic kind at reasonable prices. The interior is fitted up in a thorough manner. We see a large coffee-room or dining-room, lined by stained and varnished boarding, with painted-glass windows in which are introduced in the centres representations of the Queen's Bench prison, with some of the sports in which the inmates delighted. Below is a second-class dining-room, while on the first-floor are capital reading, billiard, and bagatelle-rooms. These extensive ranges of dwellings and tavern have passed lately into the hands of the National Model Dwellings Company, which was established for the purpose of providing model dwellings for the working classes, of approved sanitary construction, in the metropolis and other large centres of population. The third row of dwellings, just commenced, will also be acquired by the company on favourable terms. The profits are to be appropriated in paying a half-yearly dividend of 5 per cent., the balance of profits being devoted to a triennial bonus and a contingency-fund. We may add, the buildings have been carried out under the supervision of Mr. W. E. Sinclair, clerk of works for Mr. Hobbs, and the same gentleman, we hear, has prepared the plans and has carried to a successful completion the details of the blocks we have described.

Nearer the Elephant and Castle some extensive buildings have been lately erected in the Borough; one of these is worth notice for its lofty front of red brick, terra-cotta, and stone. It has been erected by the proprietors of the Atlas Paper-works. The entrance, with approach to warehouse in the rear, is constructed of polished red granite piers, carrying sculptured stone heads of Atlas with the globe, which form capitals; above the cornice the front is of red brick, in which terra-cotta panels have been introduced. The stone balconette and the side bay window over the entrance give rather a pleasing relief to a façade, which is the only attempt recently made to infuse a little architectural spirit into this long neglected but important City approach. At the corner of Southwark Bridge-road and Southwark-street, Messrs. Macey and Sons, the builders, have erected a block of warehouses in red brick. This building claims notice, inasmuch as the architect has boldly availed himself of cast iron as a filling-in to give greater light as well as strength. In this instance three wide red brick piers, relieved on the face by slight pilasters, are the only brickwork in the front. A little set back from the face of these are cast-iron bays embracing two wide openings or lights; each has a cast-iron pilaster in the centre; the horizontal portions resting on these, masking the girders, form panelled dados in cast iron, which are made to agree with moulded work in the brick piers; thus a continuity and connection is maintained. The ironwork will probably be painted chocolate or bronze colour. This iron window-framing conceals the line of floors and insures rigidity and lightness. Another instance we observe in the same road, near Cannon-street end. Here a warehouse of five stories has its front entirely constructed of iron, the girders supporting the floors are carried on brick piers at each end only, and the front space is divided into three unequal divisions, the centre being the widest, by cast-iron fluted pilasters resting on dados, in a line with which the wooden framing of the windows follow. The girder-fronts are left to show

both flanges; stiffening-plates occur at short intervals, and produce a series of pannels, which are enriched by iron pateras. The effect of the dark bronze ironwork, and the light wood frames between, give a thoroughly characteristic appearance to the elevation, and the principle is worth the attention of architects who have limited frontages, and in situations where every inch of space is required for light. In Southwark-street, several large blocks of warehouses have been built, to which we may refer another time; the great aim in most of these has been to utilise every inch of the front for light and air to the several floors, in many instances crowded with goods or workmen.

We pass on to notice a very extensive and ornamental block of warehouses in Southwark Bridge-road, occupied by Messrs. Petty, Wood, and Co., designed in a very costly and showy Elizabethan style. The front is broken up by a lofty tower, finished at the top with a steep slate roof and ridge, and a gabled entrance into a yard. The materials of the front are red brick and stone dressings. The windows are numerous and have stone mullions and transoms, and the doorways have stone arches. These are rusticated by keystone-shaped voussoirs at intervals, and the whole rests on elaborate columns of rusticated character. Complex and acrobatic bits of masonry are introduced in other parts; we see an oriel window carried by a buttress with a small isolated shaft of stone springing from the outer edge of the buttress, more for the sake of ornament than use, and the corner-round turrets at the upper part of the tower have similar devices supporting them. Between the windows are buttresses with semi-Classical details. Very seldom have we seen buildings of this class carried out in such a florid and expensive style. The warehouse does not seem the fittest building for the exercise of capricious or whimsical ornamentation, and the caprice is rendered more apparent from the severely commonplace character of the adjoining buildings. Opposite, a valuable freehold frontage is to be let on building leases, and in a few years this neglected thoroughfare will, it is probable, receive renewed attention for business purposes.

THE WATER QUESTION.—XIX.

A REGULATING DAM.

THE basis of calculation of the size and cost of a dam to arrest the flow off the ground of excessive rainfalls—in contradistinction to a reservoir for the supply of water the year round, such as that last described—is a depth of $\frac{1}{2}$ in. of rain-water, over an area not exceeding 2,000 acres, considered as one rainstorm, and falling in a day, or two days, or in whatever time such a fall of rain takes place, the absolute quantity of water produced by the whole rainstorm being that for which provision is to be made. In a former article we said that in the regulation of the flow of water off the ground in excessive rainstorms it would be necessary to consider the ground acre by acre downwards from the top of every hill, and that floods might be arrested by numerous dams in the minor watershed areas and discharged gradually. For this purpose let an example be taken of a dam to be constructed for a watershed area of 1,000 acres or thereabouts. Four inches in depth over 1,000 acres of ground is equivalent to 14,520,000 cubic feet. This quantity would not all reach the dam as a flood; part of it would be absorbed by the ground and yielded as minor springs issuing from the superficial strata after the cessation of the heavy rain, and some part would be evaporated. If 3 in. in depth over the whole area be taken as the quantity

which would actually reach the dam in a short time, it would be a reasonable quantity to provide for, and would probably meet the requirements of the case. This quantity would be 10,890,000 cubic feet; but let the quantity to be provided for be taken at 12,000,000 cubic feet, as has, indeed, before been stated. The height of bank for this quantity would be—following the same proportions as before—about 40 ft., and the area of land required might be about 20 acres, if a separate dam be made, and that may be considered in the first instance to be so, and afterwards the same provision may be considered as being added to the capacity of a reservoir of supply, suitable for the same situation; for, according to the circumstances of any position in respect of demand for water-supply, it may be proper to make either a regulating dam solely, or a reservoir for the supply of water the year round with the addition of space equal to that required for a regulating dam suitable for the same situation. If, then, a regulating dam be made with an earthen embankment 40 ft. high and 400 ft. long, on a site having the proportions already referred to, with a puddle trench of such depth that a line drawn straight from a point 40 ft. below the surface at the middle of the bank, to a point 10 ft. below the surface at each end of the bank, representing the average bottom of the trench, the following amount of work would have to be performed, approximately:—The seat of the bank to be cleared of objectionable material would be about 6,000 sq. yd. The excavation of the puddle trench about 4,000 c. yd. The quantity of puddle about 6,400 c. yd.

Deducting the quantity of puddle in the wall, the embankment would be 24,000 cubic yards, of which about 2,500 would be rough stone at the foot of each slope, and 7,500 cubic yards of selected material to be placed on each side of the puddle wall, and the remainder of the earth would be 14,000 cubic yards. The pitching of the inner slope with stone would cover about 3,000 sq. yd. The soiling of the outer slope would be about 2,400 sq. yd.; the roadway over the embankment 600 sq. yd.

The culvert would be laid at about two-thirds of the depth of that of an embankment 60 ft. high, as in the former example. Its length would also be about two-thirds, and the quantity of excavation for this culvert would be about 4-9ths of that of the former one. The cubic quantity of brickwork in the culvert, per lineal yard, would be about 9-10ths of that of the former culvert, and, its length being two-thirds, the cubic quantity of brickwork in this culvert would be about 3-5ths of that in the former one. There would be nearly the same quantity of concrete per lineal yard of culvert, but only two-thirds in the whole length.

The way in which the water would be discharged in this case would be different from that in the other, where a pipe would be laid through the culvert up to a valve-tower, and the water drawn off from near the surface. In this case it would be discharged from near the bottom only. The sluice would be always open; but inasmuch as it would be desirable that the same quantity of water should be discharged in the same time, as per minute or per second, at whatever height the water may stand in the dam, and inasmuch as the quantity discharged through the same area of opening would increase with the rise of water in the dam, it would be desirable to diminish the area of the opening as the water rises, so that at all times the same quantity may be discharged per second. The sluice would be constructed so as to open or close automatically with the rise or fall of the water in the dam. This is not a reservoir the object of which is to retain water as the primary necessity, but is a receptacle to

hold temporarily a glut of water and let it out gradually, becoming empty before the recurrence of another flood. The rate at which the water may run out can be determined beforehand in every case. In this example let it be 20 cubic feet per second.

The velocity of the water passing through the sluice will be proportionate to the square root of the height above the centre of the opening, very nearly,—and near enough for all practical purposes. If the centre of area of the opening be maintained always in the same vertical position, by reducing the height of the opening equally above and below the centre by two doors approaching each other, then the rate of motion of the reduction of the height of the opening would be as the square root of the height of the rising water, in order that the same quantity per second may pass through the sluice continually, and the intervening gear between the sluice-door and the force which moves it would have its parts so proportioned as to effect this rate of motion. The full velocity of the water through the sluice due to the force of gravity is $8\sqrt{H}$, H being the height in feet of the surface of the water in the dam above the centre of area of the opening; but the actual velocity would be somewhat less, and the effective area of the stream of water would be considerably less than that of the sluice opening; combining these effects the practical quantity of water passing through the sluice would be proportionate to five times the square root of the head in feet.

If A = the area of the sluice opening in feet,
 H = the head of water above the centre of the opening, in feet.
 Q = the quantity discharged per second, in cubic feet.

$$\text{Then } Q = 5\sqrt{H} \times A, \text{ and } A = \frac{Q}{5\sqrt{H}}.$$

The bottom of the dam would contain but little water for some feet in height, and the sill of the sluice may be laid at a level 8 ft. above the lowest point of the dam. It would still contain but little water in the next 4 or 5 ft. in height, and the zero from which to reckon the heights of the rising water in the dam may be established at 4 ft. above the centre of the opening when the sluice is fully open. The area of the sluice opening would be, for that lowest level of the water,

$$\frac{20}{5\sqrt{4}} = 2 \text{ sq. ft.}$$

And it might conveniently be made 1 ft. wide and 2 ft. high; the width remaining fixed, and the height varying with the head of water in the dam. The corresponding heights of the water in the dam and the openings of the sluice would be as follows:—

Height of Water.		\sqrt{H} .	Velocity.	Area.
Above Zero.	Above centre of opening.			
Feet.	Feet.	Feet.	Ft. per second.	Sq. Ft.
0	4	2	10	2'00
5	9	3	15	1'33
12	16	4	20	1'00
21	25	5	25	0'80
32	36	6	30	'66
45	49	7	35	'57
60	64	8	40	'50

The area of the opening, and, where the width is fixed, therefore the height of the opening also, is thus inversely as the square root of the height of water in the dam above the centre of the opening, the constant quantity discharged being 20 c. ft. per second.

A float is the essential instrument with which to make use of the force of gravity to move the sluice-door by means of intervening gear of the proper form, to reduce the

height of the opening as the water rises in the dam, by carrying up a weight (its own weight) to the top water level or to any intermediate height to which the water may rise. If the centre of the opening be maintained always at the same level, two motions of the door are necessary, which would be given by reverse gear; but if the opening of the sluice be closed from the upper side only, the centre of its area will be continually lowered, and the head of water correspondingly increased by the quantity due to half the extent of motion of the sluice-door. The diminution of the height of the opening must, therefore, be as the square root of the rise of water plus half the range of motion of the sluice-door.

There are various forms in which the gear may be made to regulate the opening of the

cistern D and into the descending pipe E, in which are two valves, F and G, connected by a spindle, so that when one opens the other closes. The spindle is continued downwards to a float H. From the descending pipe E the pipe I conveys water into the tank K, in which is another float L, connected by a chain passing over a pulley to the head of the lever M, the end of which regulates the movement of the

sluice in this way; that shown in Fig. 1 is direct in its action, simple in its parts, strong, and convenient.

A is a float, a chain attached to which passes round the wheel B with one turn, and supports at its other end a solid weight C. On the axle of the wheel B is a pinion D, toothed into an intermediate wheel E, which reverses the motion of the wheel F, which carries upon its axle a curved lever or cam, the range of which in a quarter of a revolution is equal to the range of motion of the sluice-door. To the back of this curved lever is attached the chain which draws up and lets down the sluice-door, and the form of the curve of the lever is such that the horizontal rate of motion of the chain, and therefore the vertical motion of the sluice-door, increases as the square root of the rise of water in the dam. As the float A rises from the zero level, 5ft. above the sill of the sluice, the weight C on the other side of the wheel draws up the slack chain, turns the pinion D and the intermediate wheel E, together with the wheel F and the curved lever, and lets down the sluice-door with a rate of motion such that the area of the opening is always inversely proportionate to the square root of the head of water.

The same result—that of discharging an even quantity of water—would be obtained by first discharging the water into a pond or tank below the embankment, and maintaining the water in it always at the same level.

One form of apparatus for this purpose is shown by the sketch Fig. 2. Here the discharge-pipe under the embankment is always fully charged with water. A is its outer end. B is a pipe rising from it, and the pipe C conveys water from it into the

hinged door at the end of the discharge-pipe A. When a sufficient quantity of water flows through the discharge-pipe to keep the water in the pond or tank at its proper level, the valve F is kept nearly shut by the upward pressure of the float H (and the valves being ring-valves are moved with but little pressure). If a sufficient quantity of water to keep the pond up to its proper level is not being discharged from the pipe A, the float H sinks and opens the valve F, supplying more water to the tank K and raising the float L, thus relieving the pressure of the lever upon the door and allowing more water to flow out. If too much flows out the float H rises and completely closes the valve F and at the same time opens the valve G, allowing the excess of water in the tank K to run out and the float L to lower and reduce the opening of the outlet of the pipe A. The small pipe B is carried up to the top of the bank, the water in it being under the pressure of the head in the reservoir, and the cistern D is closed for the same reason. This apparatus is described more at length in Dr. Downing's "Practical Hydraulics," but for the purpose now under consideration it is not of so suitable a form as that first described.

With the provision of a space of 12,000,000 cubic feet to receive a flood from 1,000 acres of ground, and a bank 6ft. above the level to which that quantity of water would rise, there would be no real need, probably, of a waste-weir and byewash; indeed it would be a contrariety of purposes to provide one, inasmuch as the object of the dam is to arrest the whole of a great flood, even the greatest; and if the basis here stated, upon which the capacity of a dam is calculated, is not sufficient, let it be increased; but in all probability it is sufficient. However, as no hazard must be ventured in such a case, it may be well to provide means of taking off water at the top water level fixed upon; but not a great flood, such as must be provided for in the case of an ordinary reservoir. A channel of less depth and width than would be necessary in the other case may be provided in this, and such a channel is included in the estimate following—viz.:

	Quantity.	Price.	
		s. d. £	
Clearing the seat of the bank	6,000 sq. yd.	9 2	50
Excavation of the puddle trench	4,000 c. yd.	5 0	1,000
Clay puddle	6,400 "	2 6	800
Embankment	24,000 "	1 6	1,800
Road over embankment	600 sq. yd.	2 0	80
Pitching inner slope	3,000 "	2 0	300
Soiling outer slope	2,400 "	6 2	20
Excavation for culvert	2,600 c. yd.	4 0	400
Ditto for byewash	1,800 "	1 0	90
Concrete in foundations	200 "	6 0	60
Ditto in byewash	1,000 "	7 0	350
Brickwork in culvert and sluice walls	500 "	24 0	600
Gravel puddle	300 "	4 0	60
Stone sills, coping, &c.	1,000 c. ft.	2 0	130
Footbridge			120
Girders, sluice, and other ironwork			250
			6,000
Contingencies			940
			£7,000
Land and fencing			2,000
			£9,000

There may be added to this, £1,000 for other expenses, making £10,000. This is at the rate of £10 per acre, and should free this land from liability to contribute to expenses of a river-conservancy board.

SHOP-WINDOWS.—II.

ON a recent occasion we drew attention to the aspect of our shop-windows as regards decorative materials and furniture, and pointed out a few of the circumstances that have been most concerned, during the last thirty or forty years, in bringing about their present condition. We now propose to offer a few remarks on some of the subsidiary art manufactures; and, following on the heels of the decorator, we come, first of all, to metal-work, which we shall notice under the respective heads of Iron, Brass, and Silver.

At the time of the Gothic revival, nothing, perhaps, was in a more lamentable condition than iron-work. For twenty years, or more, however, this handicraft has been in a more healthy condition; and the work turned out by firms like Hart, Son, Peard and Co., Jones and Willis, Hardman and Co., Potter and Son, and others, has been as noticeable for its truth of treatment as its beauty of design. In the early days, when the best architecture alone demanded its employment, the wrought work naturally took exclusively to Mediæval forms; but the windows of the best iron-workers of the present day—and still more our domestic buildings in all directions—give plentiful evidence that Classic work is quite as practicable as Gothic, and, better still, that work now leaves the forges good in design, and suitable for its purpose, yet exhibiting less servile copyism of any particular date or style.

In the course of the reaction from the period of castellated door-scrappers and embattled fenders, a terrible hue-and-cry arose against the use of cast iron for any purpose whatever; but more sensible views now prevail. There are many uses, well known to architects and engineers, for which cast iron is more suitable than wrought in construction: stanchions are usually cast, and girders often combine both forms of the metal. And so in ornamental work. When used in simple appropriate forms, the employment of cast iron is perfectly legitimate. But the attempt to produce, in brittle casting, those delicate features which the malleability of the metal renders it susceptible of at the forge, is a misapplication of material, and an æsthetic sham. Two very good instances of the respective uses of cast and wrought work are afforded by the large gates and railings of the British Museum and of Burlington House. Both these specimens of iron-work, each so fine in design, and yet so different in style, are an unanswerable protest against the attempts at restriction in the treatment of the metal according to its place and purpose, which the purists would inflict upon us.

The improved working of brass naturally followed quickly on that of iron, but its progress was far less satisfactory. Although the two metals differ considerably in their qualities and capabilities, yet for many long years the treatment of brass was almost identical with that of iron, and until recently it was to be seen only in the Mediaeval forms which characterised the early iron-work of the revival. It was but the other day that we were in one of the City churches, where we observed, in juxtaposition with pulpit and stalls of Elizabethan wood-carving, the altar-rails, gas-standards, and lectern, all in brasswork of the Gothic period, and elbowing an old wrought-iron Renaissance standard bearing the emblazoned shields of various civic dignitaries. Those whose tastes had outrun the Birmingham gaseliers or standards, cast in bronze or ormolu, whether Classic, Cinque-cento, or Rococo in design, could find nothing wherewith to light their drawing-rooms or dinner-tables but coronets, angular pendants, and other articles of ecclesiastical form; and the use of brass was almost entirely restricted to this purpose. But during the last few years a marked and rapid development in the working of the metal has taken place, and it now seems likely to assume for the future a very prominent place in domestic fittings. Possessing as it does, not only considerable toughness, and a ready fusibility, but high ductility, great malleability when cold, and the property of being easily turned with the lathe, it lends itself to the most varied treatment and divers uses. Latterly gas-pendants, brackets, and standards have been produced, of excellent design, combining richly curved stems with handsomely turned bosses. Fenders are now made, artificially moulded and pierced, that fully rival the old in everything but colour; and the "repoussé" work which now figures so largely in sconces and similar articles, is a most welcome contribution towards the embellishment of our rooms. The richness of colour and the brilliant polish of good brasswork have a great effect in relieving and brightening our too-often sombre apartments, particularly in the neighbourhood of the fire, where it most agreeably replaces the fenders, fire-irons, and dogs of polished steel and ormolu that are still in many houses the terror alike of mistress, housemaid, and guest. One objection is sometimes urged against the use of brasswork for domestic purposes in the amount of cleaning it requires. But this is at once obviated by the employment of a thin lacquer. Whether the old brass was different in composition from the modern, or whether time has effected some change in it, we are not able to say; but it is beyond dispute that the colour of the old is superior. The lacquer, however, like the glazing down of decorative gilding, materially enhances the beauty of the new metal, while it entirely protects it from the action of the atmosphere.

If the brazier's handicraft has lagged behind the blacksmith's, far more still has that of the gold and silversmith lagged behind the brazier's. Even when making allowance for a considerable advancement within the last year or two in this branch of manufacture, it is still, probably, the most backward of any; and the greater part of the real plate, as made at present, is "a thing to shudder at, not to see." Let anyone go to the great Bond-street houses, and inspect the racing-cups, épergnes, or presentation plate that they produce, and surely his heart will sink within him. The lessons of Cellini and the great masters of high-class metal-work, as well as the many exquisite specimens of old domestic plate, seem all in vain; and, with few exceptions, vulgarity of design and clumsy modelling are rampant everywhere.

This is the more to be wondered at, considering the great taste and demand that exist at present for good plate. The windows of the second-hand silversmiths are filled with the most beautiful specimens. During the last century the manufacture of domestic plate was at its best; and its artificers thoroughly understood and acted on the principle that, gold and silver being precious metals, no more of them should be used in the production of any given article than was necessary, and that they should receive the thoughtful design and careful workmanship which their intrinsic value demands. Hence the teapots, sugar-basins, salt-cellars, and other objects of daily use made during the Queen Anne and early Georgian periods were models of beauty and excellence of every kind, and are justly in demand by connoisseurs. But during the whole of the present century these beautiful forms, with their exquisite modelling and delicate chasing, have given place to vulgar shapes of double or treble the necessary weight, loaded with what a facetious critic once called "the knuckle-bone business," and every other variety of bad Rococo ornament. There are certainly indications of improvement. The excellence both of the old silver, and of much of the electro-plate, seems gradually to be opening the eyes of the silversmiths, and we have latterly seen several thoroughly artistic tea and coffee services of modern make.

The invention of electro-plating has effected an entire revolution in the secondary branch of this manufacture. Up to the latter part of the 18th century the only process of plating known was the clumsy method of soldering silver upon a baser metal, which had been practised from the time of the ancient Romans, and has been technically called "French plating." This allowed little scope for skill, and there is not much of such work now to be met with. But about the year 1800 was introduced the more modern system of fusing a plate of silver direct upon an ingot of fine copper or other metal, and then drawing the product into wires, or beating it into plates that could be cut, or hammered, or chased, into the desired forms. This process afforded a much greater facility for skilled workmanship, and continued in vogue during the first half of the century, till it was eventually superseded by electro-plating. This "true," or "English" plating, as it is termed, was remarkable for its strength and durability, and excellent specimens may sometimes be seen at the second-hand silversmith's, which were produced in the first years of its introduction, before taste in such matters had become utterly debased, and which thoroughly commend themselves for artistic treatment.

To Mr. Elkington, the head of the well-known Birmingham house, belongs the principal credit of having brought the process of electro-plating to its present state of perfection. As early as 1803, Brugnatelli, a pupil of Volta, contrived to gild the baser metals by means of the galvanic current, and, later on, De la Rive improved upon the process; but it was not till Rudz and some others, and notably Elkington, took the matter in hand from a practical point of view, about 1840, that electro-plate, as we now know it, had any existence. The different processes employed in its manufacture lend themselves with singular facility to varied artistic treatment. In the more elaborate articles, which are usually cast, the modelling is done in the original wax pattern; then the soft brass cast, which follows, allows of easy chasing; and the article itself, in a hard white alloy of copper, nickel, and zinc, receives the finishing touches before it enters the gold or silver bath. The manufacturers of electro-plate have not been slow to avail themselves of the capabilities afforded by the invention; and this ware has, from the first, been

marked by a general excellence of design, that sorely puts to shame its nobler prototypes in the precious metals. Of course, in a branch of manufacture that appeals for purchase to the great bulk of society, and not to a few wealthy connoisseurs only, it would be absurd to expect nothing but "high-art" treatment; and we accordingly find dogs officiating upon their hind legs as pen-holders, owls, with a pericranium like a sieve, doing duty as pepper-casters, and boating-hats, concealing a butter-dish within their inmost recesses. But the great majority of épergnes, salvers, cruet-stands, tea-services, and hosts of other articles are excellent in design. Many of these have been reproduced, or artistically adapted, from Classic or Cinque-Cento specimens, and are admirable alike for form, modelling, and chasing, tasteful in intention, and commendable in workmanship. In fine, there are few branches of manufacture in a more thoroughly healthy condition than that of electro-plate.

In passing from metal-work to pottery, we enter upon a vast field, which we can only glance at. Volumes have already been written upon this subject, and volumes may be written yet; for although everything connected with European pottery is pretty well known to experts, there is still a great deal to be learnt concerning Oriental wares. There is one thing, however, in connection with the subject, that strikes one very strongly in strolling through the streets: and that is the great increase, within the last few years, of shops for the sale of ornamental china—old or new—and articles of virtu generally: and this at a time of general depression, when people have been supposed to have little enough to spend on luxuries and curiosities! However, the shops exist, and many of the windows present a perfect feast to the eyes.

With old china we are not at present concerned. Exquisite specimens of Sèvres, Wedgwood, Faience, Crown Derby, and other choice porcelains are constantly to be met with at the best dealers in antiques. But these are things rather for the frequenters of Christie's than the general public: we are now dealing with the state of contemporary manufactures, as displayed in shop-windows. It must be evident to the most superficial observer that there has been a wonderful improvement in ceramic art during the last thirty years. It was in 1850 that Minton first commenced the manufacture of Majolica, though his encaustic tiles date back to 1828. Majolica is one of the most effective kinds of English pottery for the purposes of decoration; and, as it is now produced, the bold character, both of its design and colouring, renders it a worthy reproduction of the old ware. Its most important feature is its application to constructional decoration; and as such, it covers the floors and walls of public buildings in every direction. In 1862 the Worcester manufacture was revived by the Royal Worcester Porcelain Company (Limited), and very beautiful specimens of modern Limoges, and articles treated after the Japanese manner, are turned out from this factory. A fresh impetus was again given to the art in 1867 by Copeland (late Spode), who produced the Parian statuary which some persons so greatly admire, and who now manufactures some excellent ewers and vases of Classical shape, besides being the best English imitator of Sèvres. Many of his flower-stands, and dessert services, with elaborate centre-pieces, are extremely beautiful, and do equal credit to his designers and workmen. Ten years later the Crown Derby ware was resuscitated by a limited company; and, besides the quaint old coloured statuettes, which now greet us of yore, some of the best table-services emanate from these works, while from

Coalport come very fair imitations of Worcester, Sevres, and old Chelsea. There is a good deal of modern Dresden about too; but it is all so bad as to be worthless from any possible point of view. This, however, we do not affect to regret. However much the marvellous execution of the old Dresden ware may command admiration of a certain kind, still, everyone must admit that its manufacture constituted one of the grossest misapplications of material that a perverted ingenuity ever devised; and the sooner, therefore, that the whole thing dies a natural death, the better!

By far the most noteworthy fact of late years, connected with pottery, has been the development of the Lambeth ware by Messrs. Doulton. This has been for a long time steadily improving, and has now attained a great perfection. It may be divided into three kinds:—The “Doulton Ware” is really a revival of the fine old “Grès de Flandres,” and is produced by scratching a pattern upon the soft surface of the clay before it is fired. It is then generally coloured some neutral tint, and frequently beaded and stamped with a die, after which it receives a glaze, and passes once only through the kiln. What is called “Lambeth Faience” consists principally of hand-painted plaques of biscuit, with a dull glaze, and requires several firings. The practice of plaque-painting seems destined to become a very important branch of art. At present, it is almost in its infancy, as the management of the pigments is a matter of very great difficulty, and still but imperfectly understood. But the school which is now in work at South Kensington, and Messrs. Doulton’s spirited enterprise in the erection of large studios in their new factories, with a library and museum attached, where scores of lady-artists are constantly employed upon this work, can hardly fail to develop a thoroughly national school of china-painting. The decoration of the “Impasto” work is produced by the application of coloured clays in bold design to the surface of the article. The pattern thus stands out in relief; and additional artistic effect is imparted to it by the employment of various opaque and translucent enamels. Among all these various articles no two are precisely alike; and they combine the useful with the ornamental in the very highest degree.

Fine as the best English pottery has now become, it cannot for a moment compete in artistic excellence with the Oriental. The abolition of the old East India Company’s monopoly of trade in 1858 brought us into more immediate contact with our Indian possessions, and this, followed soon after by the opening up of Japan, created an enormous importation of Chinese, Japanese, and other Oriental wares; while the increasing taste for this class of pottery stimulated the dealers to collect large quantities of Delft from Holland, where a couple of centuries of intercourse with the natives of Japan had led to excellent reproductions by the Dutch, in earthenware, of the fine porcelains of Jeddo and Nankin. Some year or two ago there seemed some danger of a falling off in the artistic excellence of Japanese work, through the increasing familiarity with European systems of design and colouring, and the extent to which goods were made to order for this country. But the present aspect of the dealers’ windows affords ample proof that such is not the case; and specimens of Oriental ware, both cheap and costly, and finer than ever, greet us on all sides as we walk along the streets.

The rage for Japanese art has had a very mixed effect upon English pottery. On the one hand it has educated us in colour, and has taught us the true method of conventionalising natural forms; but, on the other, it is seriously threatening the purity of our designs. The peculiar *extempor*

power—if we may use such a word—of the Japanese artist, whereby, with a few bold touches of his brush or pencil, he can throw off, anywhere, a flower or spray with all the truth and vigour of natural growth, or make a bird come swooping down from the clouds, has no existence among us; and the attempt at such treatment by (*dis*)arranging fans, beakers, and ill-drawn poodles higgledy-piggledy over plates and dishes has simply resulted in a miserable fiasco. Table-services, indeed, are considerably behind most others forms of pottery. Notwithstanding the great demand for blue and white, and the numerous specimens of Nankin and Delft, that would lend themselves most happily for adaptation, as the centre of a set design with suitable borders, so arranged as to define and emphasise the form of the article in accordance with the best European traditions, there is hardly a single satisfactory pattern to be found, if we except the good old “willow,” which, always perpetuated in common earthenware, was, a few years ago, reproduced in china. Some of the best of these services come to us from the factories at Copenhagen, the chief of which is under State management, a speciality of their productions being the clever reproduction of Thorwaldsen’s models in biscuit and terra-cotta. Notwithstanding our shortcomings in certain branches of the manufacture, and in spite of a vast deal of utter rubbish produced for the benefit of the unenlightened, the present condition of ceramic art in this country shows immense vitality and increasing promise. This will be amply evidenced to those who remember the figure that we cut in the First Great Exhibition, and can revert, in their mind’s eye, to the successive Exhibitions of 1862 in London, and of 1867 and 1878 in Paris; and, lastly, will take the trouble to inspect the windows and showrooms of the best dealers in English and foreign pottery. “Excelsior” has long been, and is likely to continue, the favourite motto of the English potter.

(To be continued.)

FISH-MARKETS FOR THE METROPOLIS.

SEVERAL schemes are before the public for increasing the inadequate fish-market accommodation afforded at Billingsgate. The site at Blackfriars, suggested by the engineer and architect to the Metropolitan Board of Works, has been recommended for adoption, and will be considered by the Board at their meeting to-day (Friday), when they will be asked to seek Parliamentary powers next session to acquire the area. It may be interesting, therefore, to quote the report on this site prepared by these officials, Sir J. W. Bazalgette and Mr. G. Vulliamy:—

“The instructions appear to limit our selection of sites to the neighbourhood of the particular railway termini north of the Thames, but we suggest that the Board should not limit its selection to that particular locality, for it appears to us that a site may be obtained on the south side of Blackfriars Bridge which possesses advantages superior to any other which has been proposed. Some of the advantages of a Blackfriars site near to the Thames are that it would not interrupt or interfere with the crowded and important thoroughfares of Queen Victoria-street and Upper Thames-street. There would be no serious encroachment on the River Thames, and the property would be of much less value, whilst all the surrounding bridges over the Thames radiate towards the south; so that, although it is close by the most crowded parts of London, the fish would be at once dispersed by the different roads from the market. It is within a mile of Billingsgate and the central markets in Farringdon-road, and is in close proximity to the neighbourhood of the Borough, where the processes of drying and curing fish are largely carried on. Its main frontage would be Blackfriars-road, which is 100ft. wide, and the railways would deliver their fish into the centre of the market. It is proposed as a market for railway-borne fish, but should it hereafter be considered desirable to unite the water-borne fish

market with it, this could readily be done by forming a wharf upon the banks of the river, which is within 300 yards of it, with convenient access to the market. This site of 6½ acres is bounded on the north by Southwark-street, 70ft. wide; on the south by York-street, on the east by Bear-lane, and on the west by Blackfriars-road, to which it could have a frontage of about 300 yards.”

Not long since, we mentioned a suggestion for forming a new viaduct approach to Billingsgate, and making an upper floor to the present market for the accommodation of vans and carts. The author of this proposal was Capt. W. E. Heath, who claimed for his suggestion the advantages of an economy accruing from retaining the market on its present site, the improving of the steep approaches now leading to and from the market, and the affording facilities for the rapid discharge of fish sent by rail. Another, and more ambitious scheme is now before us, having for its object the erection of a central fish-market, the authors being Messrs. J. J. Cayley, J. Boyes, and H. H. Bridgman, A.R.I.B.A. The projectors rest their scheme mainly on the central position, river-frontage, advantageous railway communications, and convenient proximity to passenger stations, which they claim it affords. The authors base their objections to the Billingsgate site on the evidence given in the inquiry recently held before the Inspector of Fisheries into the destruction of fish at Billingsgate, in consequence of the inadequacy of accommodation at the market. Mr. Scott’s evidence showed that the proposals for carrying out the improvements, according to plans prepared by the City architect, would be so enormous that they could never be carried out. The authors of the scheme now before us contend that Billingsgate is out of date beside the present requirements of London, and that the public demand a position that will insure rapid and complete collection, and rapid trading and distribution of so perishable an article of food.

They would construct a fish-market between Waterloo-bridge and Charing-cross railway-bridge, on the Lambeth side of the river, on an area at present occupied by a bank of mud at low water, and of a width of over 300ft. The proposed market would have a front elevation to the river commencing at about the second pier of Waterloo-bridge, and keeping the curve of the river. It would be carried on columns and girders to finish at the Surrey side of Charing-cross railway-bridge. At the back of the market there would be a space of 60ft. at one end and 100ft. at the other, which would make the market 225ft. wide. The principal floor would, according to the authors, have a frontage to the river of 910ft. and an area of 191,250 square feet, or 4½ acres—more than eight times the area of Billingsgate Market, and within 5 per cent. of that of the whole cluster of markets at Smithfield, including the Vegetable Market now being erected. The floor would be on a level with the roadway of Waterloo-bridge, and open to it. Looking at the plan prepared by Messrs. Cayley and Bridgman, which accompanies their pamphlet, we find a roadway for carts (3 carts wide) runs along the wharf side, with lines of rails and platforms in connection with the Hungerford-bridge lines, while a clear space is obtained in the centre of market floor, stalls being shown round for the semi-wholesale department and retail shops with an outer terrace 15ft. wide along the frontage. The section shows a sub-floor 25ft. below the principal floor, affording additional area for carts, with inclines from Waterloo-road to Belvedere-road. The upper floor is covered by an iron lattice-ribbed roof of rather pointed section, 220ft. span, with lights along the top. At the Waterloo-bridge end a long covered platform, with rails at the sides for trucks, is shown in connection with the South-Eastern Railway; there is also a roadway underneath connecting the sub-floor with York-road. The section shows the structure of the market resting upon three rows of iron columns, the bases of which would be about level with low water. It is said that the current of the river would not be impeded, nor the navigation interfered with, the main traffic passing through the northern arches of Waterloo-bridge. Other advantages claimed for this scheme are, that it utilises a waste space by the erection of a handsome building, that by junctions between the South-Eastern, South-Western, and London, Chatham, and Dover Railways, rapid and complete collection is insured, and that the produce from all parts is quickly brought within easy

reach of all classes of the London public. All fish could be officially examined in the trucks as they arrived, before being unpacked. Rapid trading would be insured by railway communication with the systems enumerated, the river would afford floating locomotion to and from the market, and it is suggested that steam ferries to accommodate costermongers and their barrows might be established.

Another scheme for a central market has been proposed by Mr. H. J. Lecuw, of the British Lion Wharf, Bankside, which has been supported by Mr. Cohen, M.P., and others. It proposes to place the market at Backside, extending from Emerson-street on the east, to Love-lane on the west, giving a frontage to Bankside of 270 yards; from north to south the area lies between Bankside and Great Guildford-street. By taking in other blocks of property the site could be extended to Southwark Bridge. The projector of this plan claims for it all the advantages cited in favour of the Blackfriars-site, and all the facilities for the delivery of fish by land, rail, or sea. It would be in close communication with the London, Chatham, and Dover Railway, and its goods depot.

Professor Glenny and Mr. Arthur T. Walmisley, C.E., have submitted a plan to the fish supply committee of the Corporation for enlarging the market at Billingsgate, which deserves notice. It is proposed to establish an upper retail market on the level of London Bridge. The plan contemplates the removal of the present cramped premises between St. Magnus Church and the existing market, and the erection of new and commodious warehouses, easier of access, built in four distinct blocks; the upper market being of cruciform shape, with nave and transepts, covered by a glazed roof. The authors thus describe their scheme:—

The approaches to the two markets would be quite independent of each other: the retail and public entrance facing King William-street, while the wholesale traffic would be confined to the lower level of Thames-street. Ample space would be provided by setting back the now proposed buildings, giving increased width to Thames-street in front of the market for waggons to stand while loading and unloading without obstructing the through traffic of the street, and the upper and lower markets could be advantageously connected with each other for the purposes of supply by means of lifts, without annoyance to the general public. The new buildings surrounding the retail market could be raised until the present rental is not only made up, but exceeded, and the Corporation would receive in addition to the rents of the market stalls, more floor space rentals in this situation, than they would from buildings adjoining a market in any other locality, as in the neighbourhood of London Bridge they would let on as many floors as they choose to provide; a market elsewhere could only serve as a fish-market and earn a single floor space rental. The scheme combines the advantages of providing a wholesale market on a river side site, with a retail market over the same area in a good central position, possessing ready-made approaches available to the public at large, and calculated to meet the requirements of an increasing population.

Another and important scheme for an independent market has been elaborated by a new company called "The Fish Exchange, Limited," the projectors of which have secured a site at the junction of Upper Thames-street and Queen Victoria-street, an area large enough, the prospectus informs us, for all present and future requirements, and of so much greater extent and convenience than the Billingsgate-market, that they will be able to offer salesmen their shops and standings at a rent of $4\frac{1}{2}$ l. per foot against 9d. per foot now charged by the Corporation, as well as shops for a large retail business, at a lower rate, viz., 3d. per foot. The site adjoins the proposed new line and station in Queen Victoria-street for the London, Chatham, and Dover Railway, powers for which were obtained this session. The proposed site has a good river frontage and facilities for quays and landing stages, and the river is at this point free from shipping. The approaches will be numerous. Queen Victoria-street to the east, the Embankment to the west, Blackfriars-bridge to the south, and Farringdon-street to the north are all available. The company have made arrangements with the L. C. and D. R. Co. to run fish trucks direct into their station from their new

rails, on the level of the upper or van-market, and also with the District Railway for the same purpose, thus bringing the whole of the metropolitan districts into direct communication with the market. The company's scheme appears to meet many of the objections that might be urged for a more westerly site; the railway access is not to be surpassed; and the land and river frontages leave little to be desired. The directors will commence operations as soon as the required capital is subscribed. They will make the market free and open, independent of a so-called ring, and the company will be their own salesmen for any consignments ordered to them. The capital required is £500,000, in £10 shares, £1 on application and £2 on allotment, the remainder as may be required. The site near Blackfriars-bridge has been favourably referred to by the commissioners in their report.

THE RHIND LECTURES ON ARCHÆOLOGY.

MR. JOSEPH ANDERSON delivered the first of his second series of Rhind Lectures on Archæology in Edinburgh on October 17th. The subject was "Scotland in Pagan Times;" and the lecturer pointed out, from the "finds" of silver and other ornaments that have been made in the Northern and Western islands, the influence both of a Scandinavian element in the population and of Oriental commerce at some time subsequent to the beginning of the tenth century.

The second lecture was delivered on October 20th, the subject being "Viking Burials in Scotland." At the outset the lecturer gave an account of the finding of two ancient graves in the sandhills at Ballinaby, Islay, in one of which were warlike weapons and smiths' tools, in the other objects of personal adornment. It was apparent, he said, from the nature of the groups of objects associated with the two burials, that one grave was that of a man, and the other that of a woman. The man was buried with his arms and implements; the woman with her personal ornaments and household gear. It was equally apparent, from an examination of the general characteristics of these burials, that there was an obvious absence of all indications of Christianity. But they suggested, for instance, a condition of life considerably removed from absolute poverty; they presented indications of culture and taste, of skill and industry, of manly vigour and womanly grace. But the position of the graves, with the head to the east and the feet to the west, was the opposite of those referred to by the liturgical writers of early Christian times as the proper position of all the Christian dead, who should be placed with their feet to the east, so that in rising they might face their Lord as He came from the east. And there was no feature which could be more surely relied on as an indication of early Christian burial than this orientation of the grave, which was here so plainly disregarded. There was no less obviously a complete absence of all the characteristics of art and art workmanship with which they had become familiar in the progress of their investigation. There was no Celticism apparent in the art of the decorated objects placed in these graves. The characteristics that were present were all new and strange. To find such weapons of bronze or stone as were commonly styled prehistoric deposited with the dead excited no feeling of surprise, because they knew, in a general way, that this was the common custom of pre-historic Paganism. But when they found in a grave, along with the ordinary weapons of war, a group of actual tools of iron, scarcely differing in shape and not differing in material from those now in use in their workshops, they instantly realised the presence of a phenomenon at once unusual and suggestive. It was unusual in this country, because their forefathers received Christianity early, and Christianity abolished the custom of placing implements in graves. It was suggestive, because it enabled them to see how closely the characteristic customs of the man they called primeval might be linked with the arts and culture of modern times. The most typical object in the first grave was the sword—long, broad-bladed, double-edged, and tapering slightly and evenly from head to point; in the other grave, two oval, bowl-shaped brooches of artistic workmanship—a form of ornament which never occurred within the Celtic area. The special features of the form of burial were,

that it was burial unbent or with grave goods. These were features that were common to almost all forms of Paganism. But there seemed to be a special suggestiveness in the character of the group of objects deposited in the man's grave. Since he took with him his sword and spear, his axe and shield, and his smithy tools to keep them in repair, it seemed a fair inference that his form of faith must have taught him to look for a continuance of warfare in the life beyond the grave. They know that such a faith existed, and that the Northern and Western Isles of Scotland were overrun by men who held them at a time when such implements and weapons of iron were in common use. The lecturer went on to show that the forms of the weapons and implements and ornaments found in these Islay graves were identical with those associated with Viking burial in Norway during the period between the beginning of the eighth and the end of the tenth centuries; and that the range or area of this type of burial in Scotland included several of the Western Islands, and Orkney and Shetland, Caithness and Sutherland—an area which, established on archaeological evidence, coincided exactly with the area established by historical record as that which was colonised and possessed by the Norwegians in the time of their heathenism. It was incidentally stated that thirty-two brooches of the Islay form had been found in Scotland, whereas only fourteen of a Celtic or native form had been discovered. The explanation was, that the effect of Paganism was that those who had brooches were buried with them, while the effect of Christianity was that brooches ceased to be buried with those who had them. The lecturer then spoke of ship-burial in Scotland—instances having been found of this nature—where the Viking had been buried in his war galley, and a pile of earth raised over it. They had testimony in the Sagas to this custom, and evidence had been found of it in graves both in Scotland and Norway. He had, said the lecturer in conclusion, described these Norwegian burials found in Norway and in Scotland partly because they enabled them more vividly to realise the peculiar characteristics of Pagan burial, but chiefly because he was unable to illustrate the phenomena of the Iron-age Paganism of Celtic Scotland from its own remains. The archæology of Scotland was absolutely destitute of recorded data for this purpose. The un instructed excavators had some respect for stone and bronze, but old iron was shovelled into oblivion without a moment's hesitation.

The third lecture was delivered on Monday afternoon. The subject was, "Celtic Art of the Pagan Times." Proceeding to sketch groups of relics which were not only types that were of indigenous origin and confined to the Scottish area, but which also presented in their form and decoration features which they had to recognise as distinctly Celtic, the lecturer first described a curious bronze head-piece with horns found in 1820 in Tows, Kirkcubrightshire, the ornamentation of which consisted of a series of irregularly divergent spirals in *repoussé* work, repeated symmetrically but not identically on the front of the object—the curves being sometimes arranged so as to produce a zoomorphic effect. Other objects distinguished by the same characteristics were a boar's head found at Leitcheston, Banffshire, in 1816; a bronze mirror and a crescentic collar-shaped plate of bronze found at Balmaclellan, Kirkcubrightshire, of a form usually associated with interments of Pagan times in Britain; and a circular plate of a bronze mirror obtained with other objects from a Pagan cemetery at Mount Batten, near Plymouth. A mirror found in a grave at Irelan-Bahno, Cornwall, was also referred to. These mirrors, it was pointed out, differed in form and ornamentation from Roman mirrors, and disclosed the existence of a native school of art distinctly Celtic. There were then minutely described the characteristics of objects in gold and bronze from a hoard found at Shawhill, Peeblesshire: of some massive enamelled bronze armlets, from Castle Newe, Aberdeenshire, and Pitkellony, near Muthill, and Stanhope, Peeblesshire; as also of armlets in the form of a double-headed snake, found on the east coast of Scotland at places north of the Firth of Tay. A bridle-bit, with yellow and red enamels, found at Birrenswark; and harness mountings, found in Annandale, were also spoken of as illustrating the same peculiar art in a less pronounced, but equally characteristic style. It was evident, said

the lecturer, in summing up, that they had herein the decoration of all the objects a peculiar and highly characteristic style of art, confining itself to curvilinear forms, combining its simple elements in a manner that was neither rigidly geometric nor fettered by conditions of absolute symmetry, but producing, by a rhythmic recurrence of certain features, a series of designs that were characterised by a beauty of form, balance of parts, and harmonious combination. It differed from the art of the Christian time inasmuch as it presented no intermixture of forms and features that were common to Greek, Roman, and Etruscan art—no interlaced work, no meanders, or key patterns, or fret work of any kind, and no similitude of foliage or foliaceous scrolls. It was still zoomorphic, but its zoomorphism was confined to the forms of the objects to be decorated, and had no place in the designs with which they were decorated. It was more partial to the modelling of solid forms of ornament than to the elaborate decoration of surface by intricate engraved work, and these solid forms of its surface ornament never became zoomorphic. When the graver was employed it was used chiefly to produce broad effects by the contrast between plain spaces in the designs and spaces filled with punctuations or with simple parallel lines. They found this peculiar style of art employed in the decoration of metal-work in gold and in bronze. The objects so decorated were personal ornaments, arms, harness, and horse furniture. The technical skill displayed in the manufacture and finish of these objects was great, and the quality of the art displayed was high. There was implied in their production a special dexterity in preparing moulds and compounding alloys, in casting, chasing, and engraving, in the polishing and setting of jewels, in the composition and fixing of enamels. But there was also implied an artistic spirit controlling and combining the results of these various processes, giving elegance and beauty of a peculiar cast to the forms of the objects, an increasing the intrinsic elegance and beauty of the form by the harmonious blending of its special varieties of surface decoration, in which forms that were solidly modelled were intermingled with chased or engraved patterns and spaces filled with colour. A style of art characterised by such originality of design and excellence of execution must count for something in the history of a nation's progress, must have its place to fill in the history of art itself, when once they had begun to realise the fact that art was not the exclusive privilege of classic antiquity. (Applause.) The most peculiar and characteristic feature of an art so singularly decorative was the fact that it was applied so largely in the ornamentation of objects that were appropriated to the commonest uses, such as the trappings of horses and harness of horses. Philostratus, a Greek writer, who came to Rome at the commencement of the third century, had left them the information that the barbarians of the ocean spread colouring matters upon glowing brass, which thereby adhered to it and became as hard as stone, and thus preserved the designs made by them. It was matter of inference what the people were here styled "barbarians of the ocean"; but it was matter of fact that in the context he was speaking of harness and horse-trappings, and that horse-trappings of bronze decorated with coloured enamel were found only in Britain and in Gaul. Those found in Britain were by far the more abundant and richly decorated; and there was evidence that they belonged to a time when the Celtic population had not been exposed to the influences of Roman forms of culture. In the group of objects described in this lecture they had, therefore, a series of examples of the art which characterised the Iron-age Paganism of Scotland—the period that lay beyond the Christian time, and reached back till it merged in the Bronze-age culture. The phase of art which they exhibited, in its broader aspects, was not confined to Scotland alone. Its germs were found in the Iron-age decorations of Central and Southern Europe; but this peculiar system of design, which only appeared feebly and imperfectly among the relics of Continental culture, received its highest development in Britain alone. There it became a distinctive school of decoration, exhibiting different aspects in England, Scotland, and Ireland, and attaining in each of these areas a separate individuality. In Scotland and Ireland it became the prevailing and dominant style throughout the

period intervening between the close of the bronze age and the richer development of art in the style peculiar to each of these countries in their Christian time. It had been shown in the last course of lectures that Scotland possessed a national school of decorative art which flourished throughout her early Christian time, distinguished by an intense Celticism of style and character, expressing itself specially in the employment of certain elements of design which were not characteristic of the art of any other people. It had now been demonstrated that these elements which gave intensity to the Celticism of the early Christian art of Scotland were carried on into it from the prevailing culture of the preceding Paganism of the Celtic people, among whom they existed in perfect purity as a school of early Celtic art, absolutely unaffected by the influence of Roman or other extraneous forms of culture. He had still to show that in these early ages there was also in Scotland a distinctively Celtic school of architecture, producing forms of structure of such absolute originality of constructive character that nothing like them was known beyond her own borders. In the next lecture (to be delivered to-day) he should deal with the architecture of the brochs, or great dry-built towers—the prehistoric castles of Scotland.

FIRE-RESISTING STRUCTURES.

WE recently referred to a few destructive fires in the City, and among them we mentioned one which occurred at Messrs. Foster and Co.'s premises in Cheapside. As our readers were then informed, the whole interior of four stories, besides a basement, was clean burnt out, leaving a shell of crumbled stone piers on the two frontages. These fragile remains were held together entirely by the framework of iron girders, for they otherwise must have collapsed, to the danger of adjoining property, as well as of the lives of those engaged in extinguishing the fire. We have just received a set of well-taken and printed photographs showing the result of the fire on the ironwork, and they are instructive as well as interesting records of the event. In this instance the contents of the building were of a very inflammable description, and the action of the fire, fanned by currents of air from both sides, was of the most intense and trying kind. If any ironwork was exposed to danger from fire the columns and girders of this warehouse were certainly so, and to a very serious extent. The flames soon acquired an uninterrupted play from basement to roof, as there was no arching and concrete to the floors. The chief point worthy of attention in the building under notice is that the ironwork, after the raging fire to which it was exposed had abated, was found almost intact, while all the wooden joists and flooring were consumed.

The structure was designed and carried into execution by Messrs. Ford and Hesketh, architects, of 21, Aldermanbury, and the iron construction, adopted by those gentlemen and put up by Messrs. Measures Bros. and Co., of Southwark-street, appears not only to have tied the walls together, but also to have resisted the action of intense heat, and have remained undisturbed. We have thought it would be acceptable to our readers to lay before them a few of the details of the iron-construction, supplied and carried out by the latter firm. The warehouse covered a rectangular area, and there was a basement which extended under it. With the ground-floor it was five stories in height. On the return side, the building comprised four bays, and on the Cheapside front three bays. A series of double transverse girders crossed the building at every floor, supported on the piers on the outer side and the party-wall on the inner side, and in the centre they were assisted by east-iron columns varying from 9in. diameter in the basement to 6in. in the upper story. These pillars, which rested on one another, varied in height; those of the basement were 10ft., the ground floor 14ft. 6in., the first floor 12ft. 6in., the upper floors 11ft. 6in. and 10ft. 9in. in height. They were hollow 15-8in. thick of metal in the basement, and the upper ones were 7in. thick. The manner these were attached to the plate girders deserve notice. The latter were of rolled iron of I-shaped section about 12in. deep; a couple of these girders rested on the edges of the

abacus of the iron pillar, which was accurately faced to receive them, and were connected together at 4ft. intervals by gas-tubing screwed up at the ends. The flanges were drilled and bolted to the bed-plates, but there was no play allowed for expansion, &c., moreover the ends of the girders which rested on the wall and piers were tightly bedded into them. This arrangement of girders allowed the pillar shafts to run through and to be bolted together with a flange joint. In the other direction these girders were stiffened by single binders or cross girders of lighter section, which helped to keep the main pairs in position. The wooden joists rested on filets on the lower flanges of the iron girders. Perhaps the most noteworthy feature is that the columns were not coated with plaster or cement, which is known to afford considerable protection to them, but were fully exposed to the action of the fire. The five tiers of them were fiercely swept by the flames, but the only visible sign of their ravages is the burning off of the paint with which they were coated. The construction of the columns and their connection appear to have admirably resisted the trying test to which they were exposed. The bases were cast with ribs, and the columns were connected by flange-plates. The other ironwork supplied by Messrs. Measures Brothers and Co. also fully withstood the ordeal of fire and water to which it was exposed; the main façade rested on a triple-plate girder supported on cast-iron columns, which has not shown any signs of yielding, although a great dead weight rested on it. One other point of some moment is, that the ends of the iron girders were tightly fixed in the brickwork on stone templates. The mass and length of iron did not warrant the architects or engineers in making any allowance for contraction or expansion, and the result has, at least, justified this manner of construction. Opinions on this, as well as other points, differ considerably as to the effect of fire on ironwork. It has often been contended, and in theory it is quite sound, that no ironwork should be tied rigidly to the walls of a building. The chief fact to notice is, that the main girders were continuous from end to end. What might have happened if the ends of these girders had been left free to move is almost too apparent. The stonework, completely pulverised in places, would have been without rigid support, and its destruction would have been inevitable. This point, at any rate, is one upon which architects and engineers will continue to differ. In this instance, to the rigidity with which the ironwork preserved the flimsy shell of stone, alone is attributable the safety of the outer walls. The only girders bent are those in the rear of the building, which were exposed to the action of the fire on one side, and these were of small section.

We must say a word in praise of the beautifully clear photographs before us, taken by the London Stereoscopic and Photographic Company of Cheapside. One of these shows the whole ruin as it appeared on the 1st of September last, being a perspective view taken at a considerable height above the street-level on the opposite side. The architectural features of the Cheapside façade are clearly shown, even to the capitals and the pilasters which divided the windows and the lofty terminals of stone above the open parapet. The main and cross girders are also distinguished. Another view shows to a larger size, and from a nearer point of sight in Bread-street, the largest part of that front and its ruined interior. The iron window stanchions which divided the openings and the cross girders are discerned with great distinctness, while one of the raking iron principals of the roof of a similar section to the joists is visible. This photograph has, however, a special interest to the architect in showing the disintegrating action of fire on the stonework. Every stone is clearly brought out, and the crumbled masses of piers and lintels, the calcined jambs and shafts tell a tale of the greatest import to the builder in stone. The representation is a perfect photographic picture, and the value of photography in recording substantial facts of this kind cannot be overrated. The third photograph shows one of the angle windows over the ground story in Bread-street. Here through the opening we see two transverse coupled girders with their tube-bolts *in situ*, unscathed, resting on the capitals of the columns, which are perfectly plumb and equal to their original

duty. We can see also the stiffening cross binders at intervals already described, and every detail of importance. One cannot examine this scene of desolation, or look at these photographs without being led to conjecture what might have been the effect if no ironwork had existed to retain the fragile mass of calcined stonework in its place, or if the girders had not been tied together; nor can we doubt that had the iron joists been immersed in concrete, or protected by concrete flooring, the fire would have been confined to a single floor instead of devastating the whole building. We may add, in conclusion, that a careful examination has shown no material deterioration of the ironwork; the main girders are quite as straight as when first put in, and the brusses of iron are absolutely unaffected. The greatest deflection occurs in two of the main girders, which have cambered or bent upwards, owing to the action of the fire on their upper flanges. The best proof of the excellence of the work of Messrs. Measures Brothers and Co., is the fact that the old iron-work, which has been carefully shored up in position in parts left without support, is to remain, and the new masonry is to be built up to it again.

SANITARY EXHIBITION AT BRIGHTON.

IN connection with the Health Congress to take place at Brighton in December next, of which Dr. B. W. Richardson, F.R.S., will be the president, it has been decided to hold a domestic and scientific exhibition in the Royal Pavilion buildings, in that town. The exhibition will open on Monday, Dec. 12th, and will be closed on Wednesday, Dec. 21st. It will be divided into eight sections, those of (1) food products; (2) domestic, household, labour-saving and educational appliances; (3) house sanitation, this section including also hospital construction and appliances, and personal hygiene; (4) industrial dwellings, in model and plan; (5) electricity; (6) decorative art and photography; (7) horology and scientific instruments, and (8) art loan collection. From the conditions we learn that the gold, silver, and bronze medals will be awarded while the exhibition is open, in order that exhibitors may display them.

MR. STREET ON THE ROYAL ACADEMY.

AT the dinner given at the Mansion House to the members of the Royal Academy on Wednesday, the Lord Mayor, in proposing the toast of the evening, associated therewith the name of Mr. Street, "who had given to Justice a palace of which the nation might well be proud." Mr. Street, speaking with regret of the absence of the President of the Royal Academy, said it was impossible for Sir Frederick Leighton to return from Italy in time to be present at the banquet. The Royal Academy had been created by Royalty and carried on by a democratic constitution, which had worked such changes in its position that much might be expected from the prestige it had acquired. The work it carried on might be divided into two classes—that which was seen and that which was not seen. Of the first kind was the holding of exhibitions of the pictures of modern and living artists in the spring, and of the works of ancient and deceased artists in the winter. With regard to the exhibitions of works of living artists, he might point out that they not only proved sources of gratification to all interested in art, but that they afforded to young artists who had their spurs to win opportunities for gaining distinction, and instances were neither few nor far between in which the entrance into the world of popularity and favour dated from the exhibition of a good picture on the walls of the Academy. Dwelling next upon the great value of the exhibitions of works of old masters at Burlington House, he alluded to the difficulty the Academy still found in prevailing upon the owners of such valuable works to part with them even for a time. Turning then to the unseen work done by the Royal Academy, of which little was known by the public, he briefly described the schools of the Academy, in which masters, models, and casts were provided, and some 400 students were at present receiving their education. They were taught by competent masters, and were visited by 23 visitors elected by ballot from among the members of the Academy. Thus the

students were brought into intercourse with some of the most distinguished artists of the day. It was, too, worthy of note that the students received this education without payment, and that a whole profession were in this way educated without cost to itself by a society which had no subvention and no aid from the State—a case, he believed, unique among the art schools of Europe. Referring to Blackfriars-bridge and certain works contemplated at the Guildhall, he expressed a hope that when the architect had done his part, the sculptor and painter would be called in to complete the decoration of the structure. He hoped that the arts of architecture, sculpture, and painting would be so cultivated in this City that in future years people might think of London as they now thought of the old centres of civilisation and art elsewhere in Europe.

LIVERPOOL ENGINEERING SOCIETY.

THE fortnightly meeting of this Society was held on Wednesday evening, Mr. A. Helt, President, in the chair. A paper, by Mr. William Kissack, Stud. Inst. C.E., on the "Extension of the Promenade at Southport," was, in the absence of the author, read by the honorary secretary. The work, Parliamentary powers for which were obtained in 1876, consists of a promenade 25ft., carriage-road 25ft., and footpath 10ft. wide, formed on an embankment 12ft. above the level of the shore, inclosing 42 acres of land reclaimed by it. This land was bought by the corporation at a cost of £9,000; roads and sewers have been constructed on it, the portion between the roads has been filled up to a height of 2ft. above the top of the sewers, and is now being sold in building plots. By the sale of the land the corporation will recoup the whole of the money expended on the works. The sand for the embankment was brought by a line of rails laid along the shore from the sandhills at Birkdale, a distance of 2½ miles, being filled into the waggons by a steam "excavator," which filled 300 four cube yard waggons per day, thus doing the work of 70 men. The embankment is protected by a sea wall made of concrete, consisting of one of Portland cement to six of sandstone, broken to pass a two-inch riez. The concrete was deposited in layers 6in. thick, and punned with a 30lb. rammer. The toe of the wall, which is 2ft. 6in. thick, is 20ft. out from the face of plinth, and it rises with a gentle curve to the finished surface of the promenade, where it is 1ft. 6in. thick, and is finished with a plinth 2ft. high, surmounted by an ornamental cast-iron railing. The top of the plinth is 8ft. above high-water mark of a 21ft. tide, which is the highest known, and is provided with "weep holes" at intervals of 6ft. There is an approach-road to the shore at Seabank-road end, with a gradient of one in fifteen, and opposite each new street is a flight of steps of concrete. The promenade and carriage-way are laid with asphalt on stone pitching, and the footwalk is tiled with Welsh fire-clay tiles. The works, which comprise 400,000 cube yards of embankment, 8,000 cube yards of concrete, 24,000 square yards of asphalt, and four miles of sewers, have been carried out in an exceedingly creditable manner by Messrs. Gripper and Bayliss, of Westminster, at a cost of £32,000, and are from the designs of the borough engineer, Mr. W. Crabtree, Assoc. M. Inst. C.E. A vote of thanks to the author for his interesting paper was given, and the chairman announced that the next meeting of the society would take place on the 7th November, when a paper on "Tides and Tidal Scour," by Mr. Joseph Boulton, would be read. The first volume of the *Transactions* of the Society is now ready for distribution, and reflects great credit on its editor, Mr. W. S. Boulton.

PAINTERS' WORK.

THERE are several ways in which painting is measured and valued, and it is to be regretted that painters are not agreed upon some uniform rule for ordinary work. The rules given in some of the surveyors' handbooks are vague, and at variance with practice. Mr. Leaning, in his recently published book on "Quantity Surveying," recommends a rational system of measurement, which is as follows:—"Look through the dimensions from the beginning after

they are squared, and repeat the dimensions of the squaring column, multiplying by a figure according to the kind of work, as 1ft. for plain where no edges, 1ft. 2in. where there are edges, 1ft. 3in. where square-framed or moulded." Another method is to abstract the quantity directly from the bills, adding one-seventh for edges. Knetted, primed, and stopped work ought to be mentioned, also the number of oils, the priming being one. The description also ought to state, if party or extra colours are used, and the material painted, if iron, wood, brick, or cement, each kind being kept separate. Painting is measured at the yard square with the exception of a number of articles which can hardly be measured superficially.

Any work which is "cut in both edges," to use a painter's phrase, is measured by the foot run. Such things are skylight-bars and rails, shelf-edges, eaves-gutter, balusters, railing; small articles, such as gratings, rain-pipe heads, hinges, latches, &c., are numbered. With reference to the rule for measuring windows, most authorities take the squares per dozen; where the sashes are in one square, they are described as "sheets," counting two for one, to allow for both sides. When over 2ft. superficial, squares are called large squares; ordinary squares are taken per dozen, counting two for one, to allow for both sides. For painting window-frames, superficial measurement is taken for each surface. Over 24ft. superficial, they are described as "large frames," over 36ft. as "extra large frames." Graining and varnishing, staining, sizing, and varnishing, are measured by the yard superficial, the stain and coats of varnish, &c., being described. Oiling and rubbing and varnishing are taken in the same manner. Grained work is taken as an extra upon the plain work, and the description should give particulars, if the work was "combed," "grained," and "over-grained," and the times varnished. "Flatting" is also taken as an extra.

It is more difficult to measure decorative work, and here few rules can strictly be observed. Such work must consequently be measured in detail, or valued according to time occupied. Mouldings, for instance, which are picked out, cornices in different colours, ought to be separately described, and the picking out, gilding, &c., be defined. If painting is abstracted from dimensions of joiner, the measuring-book will show the superficial, say, of 4-panel square doors, and after it a circle may be drawn with "4 grain and 2cc varnish" inserted in it."

MUNN'S VENTILATOR.

MESSRS. JAS. M'HAFFIE AND CO., of Glasgow, the makers of Munn's Patent Exhaust Ventilator and Smoke Cowl, being desirous of having a trial made of the merits of that apparatus by some independent person, recently applied to Principal Jamieson, of the Glasgow College of Science and Arts, to conduct some experiments. The result was that Principal Jamieson determined to adopt the ventilator for the college buildings, and he has since submitted the following report to the makers:—"College of Science and Arts (Incorporated), 38, Bath-street, Glasgow, 14th October, 1881. Messrs. James M'Haflie and Co., Calderwood-street, Parliamentary-road. Dear Sirs,—Last session we found considerable annoyance from want of ventilation in our Junior Mathematical Practical Chemistry, and small as well as large hall class-rooms. I reported this defect to my directors, and they desired me to look out for the best system of ventilation. I inspected several ventilators; amongst others Munn's Patent, as fitted by you to the Free Tron Church, Glasgow. During a Sunday afternoon service, when the church was well filled, I had eight self-registering thermometers placed in different positions throughout the church, to test the rise of temperature, and also observed the quantity of air passing through the ventilators by means of a good anemometer. This, as well as two other tests which I made during different states of the atmosphere, satisfied me; and, in consequence of my report, we have had two of Munn's 15in. ventilators placed upon our roof here, and connected with the large hall, holding 350 persons; the small hall, 100; the mathematical class-room, 110; and the practical chemistry laboratory requiring special good ventilation. Similar tests to those already mentioned were carried out during our opening lecture, on 3rd

in-t., when the large hall was crowded in every corner. These tests, along with others since made, and a thorough inspection of the work as fitted for us, convinces me that we have got a reliable system of ventilation, with good working ventilators. I can, therefore, recommend Muon's Patent for schools, colleges, and churches, and shall be willing to let any one desiring better ventilation inspect the system erected here. —Signed ANDREW JAMIESON, Principal."

PRACTICAL NOTES ON PLUMBING.— XVIII.*

By P. J. DAVIES, H.M.A.S.P., &c.

INSIDE WORK, OR SANITARY PLUMBING.

UNDER this title, it is my intention to describe and give illustrations of the various kinds of work in this branch of the trade, many of which will be copies of work executed by myself.

My readers will save themselves much trouble by noticing that in all my diagrams the various parts with their proper initial letters, and in fixing work I always adopt the same plan on the work itself. Here follow a few instances as explanation. S.V. stands for soil-ventilator, M for main, C closet supply, D diet tie, S soil-pipe, R.W. rain-water pipe, W waste-pipe, F flow-pipe, R return-pipe, L.W. lavatory-waste, and so on, according to the name of the part.

Wherever this plan is adopted, and written or printed, in any closet, any plumber being called in to effect repairs can see at once where to take off another supply, shut down a pipe, &c., &c., without taking half a day to trace pipes. This is especially convenient in cases of burst pipes during frosty weather.

This cistern, 1, is lined with lead wiped all round the angles, as shown at A A A (in a future number I shall devote a chapter giving minute details on the work of lining cisterns); 2 is a 1½ in. standing trumpet-mouth waste, which is ground into a washer, 3, and soldered flush into the bottom of the cistern. This, of course, answers two purposes—as an overflow, and as a means of washing out the cistern. The cistern is supplied by a ½ in. main-pipe, M (by some waterworks people it is called the communication-pipe, as also in the Water Act, or Water Companies' Regulations of 1872). I shall, however, adhere to the proper title, "main-pipe." At the end of this main-pipe is soldered on the ball-valve, 6. C is the closet-pipe leading from the bottom of the cistern; by means of a flanged joint a 1½ in. strong spindle-valve, 4, is soldered to the end of this pipe, which is kept open by hooking it up on a large nail, 5, with stout closet-wire. 7 is another leaden cistern, having a standing waste, 8, and 1 in. dietie-pipe, D; this pipe supplies all water to sinks, lavatory basins, baths, &c., which is also governed by the 1½ in. spindle-valve 9, and a separate 1 in. hot-feed pipe leading to the bottom of the hot-water tank, as shown at H F H F. On the mouth of this pipe is also fixed a ½ in. spindle-valve, and hooked up as shown at 11. This cistern is supplied with water through the ball-valve 12.

HOUSEMAID'S SINK.

Fig. 13 is a housemaid's sink, lined with lead and soldered 16 in. up the angles, as shown at A A A. W is the waste-pipe from the cisterns; H a ground-in gunmetal cock, with a spanner to turn it; C the cold-water cock coming off the pipe.

Fig. 14 is a round hopper-closet basin fixed into the dip of a trap 15. A 5 in. strainer with 1 in. hole is dropped into the bottom of this basin, which is kept in its place by a piece of lead 3 in. deep, tapered to the shape of the basin, and fitted as shown. The top of the basin stands 2 ft. 2 in. from the floor line, and the front of the sink 5 in. higher, in all 2 ft. 7 in. The lead from the bottom of the sink is worked down into the basin, as shown at 16, and the basin is flushed with a 1½ in. pipe and spindle valve, 17 in. cistern 1. In the side of the trap is fixed a ½ in. cup and screw, 18, and the waste or out-go pipe, H—S.W. (housemaid's sink) is 4 in. branched into the soil-pipe S, which is continued to the top of the cistern, and has a Stevens' exhaust cowl, 27, fixed on the top; 19 is a white washing basin, 14 in. over, 2 ft. 6 in. high, having

hot and cold water, as shown at 20 and 21; 22 is a 1½ in. trap and waste-pipe, L.W. (lavatory waste); 23 is the overflow from basin to heel of trap, fixed 5 in. above the water line. By tracing the pipe L.W. it will be seen that it does not discharge itself into the soil-pipe, but into another and separate waste-pipe, W. On the top of the trap, 22, is branched a 1½ in. ventilating pipe, 24, continued up above the roof, and having a "Weaver's" cowl, 25, fixed on the top. The 2 in. waste-pipe, W, is continued to the top of the house, and has a Buchan's ventilator, 26, fixed on the top. The hot-water tank has a piece cut away from the side, in order that you can see the method of fixing the end of the flow-pipe, F, above the

EXHIBITION OF WORKS OF ART APPLIED TO FURNITURE, 1881.

THE following is the Report of the judges appointed by the Council of the Society of Arts to make the awards of silver and bronze medals offered by the Society to the Designers and Art Workmen whose work is exhibited in the Exhibition of Works of Art applied to Furniture, held in 1881, at the Royal Albert-hall.

1. The collection of works of art included many branches of artistic handicraft, such as carving and inlaying in wood, ivory, &c., cabinet work and fine joinery, painting on various materials like wood, glass, and pottery, gilding, the process known as *pate sur pate*, beating and chasing metals like silver and brass,

end of the return, R. The flow is the hot water from the boiler-pipe. The return is the cooler water passing from the hot-water tank to the boiler, where it mixes with the hot water, and again ascends in regular order. (This will be explained in detail in a future article.) This is known as the close tank system, and no draw-off pipe be at any other place than off the top, at 28.

Fig. 20 is the vent pipe, which must be well protected from frost, and taken above the water-line in cistern 7.

Fig. 30 is the manhole in the tank, to clean out or screw up the fittings. N.B. The air or vent-pipe, 20, must never be taken the least below the top of the hot-water tank, but be fixed to the top with a proper flange.

The pipes, F R and H F are fixed with back-nuts and grommets on the side of the stationary back-nuts, because then the turning round of the nut does not turn the grommet away.

(To be continued.)

wrought-iron work, modelled and glazed stoneware, and decorative needlework. The arrangement of the objects had been undertaken by the various exhibiting firms. A definite space had been assigned to each firm, who decorated it with hangings or with painted and gilt model work, or wood paneling, &c., and then disposed within it the various objects of furniture, &c. We were much pleased with the general good taste displayed in the separate divisions and in the aspect of the Exhibition as a whole.

2. In Ray No. 1, exhibited by Messrs. Grace and Son, the important cabinet of carved walnut wood was distinguished for its excellence. A number of hands, it was stated, had been employed upon the carving which called forth our admiration. It was, therefore, not possible to single out one art workman to whom a medal might have been awarded. For the same reason no distinction could be awarded in respect of the admirable mild octagon table of walnut wood, the design for the ornamental border of which has been made by Mr. J. D. Grace. The painting done upon a cabinet of satin-wood, by Mr. Herman Seely, as well as the delicacy of his rendering of the little figures of boys in the medallion, merit the distinction of a Bronze Medal. It is Ray a tray and set of three things, in a dark, olive-green tone, ornamented with applications of well-modeled forms in white paste, exhibited by Messrs. Munn, and designed and executed by Messrs. Seely, was specially commended as worthy of a Silver Medal.

3. The decoration of the side of a room, exhibited by Messrs. Morant, Boyd, and Blanford, remarkable for the excellence and finish of the work, was based upon a scheme good in its proportions, and the blending of the delicate tones of colour adopted, with those of the damask panels, and the details of the ornamental forms used, redound to the good taste of the designer, Mr. V. Barnard. Messrs. Morant, Boyd, and Blanford also exhibited a satinwood cabinet, and we consider that Mr. H. Reich, who inlaid the frieze of interlacing garlands upon the front of the drawer and the central ornament of the flap, should be rewarded with a Bronze Medal.

4. Near Bay No. 2 hung three red lustre plates, the work of Mr. W. M. Ryan, to whom a Silver Medal should be given for suitability of design to the materials employed, as well as for the fine tones of colour and lustre obtained.

5. In Messrs. Jackson and Graham's cabinet and chimney-piece, of a so-called Oriental Greek character, extraordinarily delicate and perfectly fitting marquetry work, and very finished cabinetmakers' work, attracted attention. A Bronze Medal is due to Mr. A. Reich, the marquetry worker, and a Bronze Medal to Mr. A. Baldwin, cabinet-maker; to Mr. Marchant, who is understood to have assisted in the cabinet work, we award one of the Society's Certificates. Beneath the chimney-piece in rosewood, with plaques of inlay of ivory, ebony, and mother-of-pearl, designed by Mr. Allwright, was a wrought-iron grate, of simple design, in good taste, made by Mr. Sayer, a member of the firm of Messrs. Feetham and Co., who exhibited other grates and fire-irons of good pattern and workmanship. A piece of embroidery, designed by Mrs. Alfred Morrison, who presented the colours and selected the materials used, greatly pleased us by the excellent distribution of Oriental motives, as well as the beautiful harmony in colour displayed in it.

6. The walnut seat for a vestibule, understood to be a copy of an old French design, reflects great credit in respect of its workmanship upon the exhibitors, Messrs. Gillow and Co. The carving, by Mr. M. Anderson, of the pendent leids of the canopy, and scroll-work on the arms of the seat, is well done. Carving in satin-wood of garlands, on a small scale, but in high relief, and also of medallions, with a layer of satin-wood upon a ground of ebony, in imitation of cameo cutting, executed by Mr. Ross, to decorate the satin-wood cabinet, made for the Empress of Russia by Messrs. Gillow, showed much skill in the execution, but in a direction of doubtful taste.

7. The carving of panels of boxwood let into a rosewood cabinet, exhibited by Messrs. Holland and Sons, was commendable.

8. In Bay No. 6, some lightly constructed furniture, including a stand in oak wood, after a Japanese model, and some chairs after good models of the Chippendale and Sheraton period, shown by Messrs. H. Ward and Co., was particularly noticeable for its gracefully designed and well-out ornamental details. A rosewood chimney-piece showed good cabinetmakers' work. The designer of these pieces is Mr. Randall, whom we select for an award of a Bronze Medal, as well as for his design for a white metal fireplace and fittings. Some extraordinary specimens of glass cutting and engraving, by Mr. Northwood, who has produced a very remarkable fac simile of the "Portland vase," probably unique as a work of glass cutting of modern times; and a vase called the "Mitt-n-vase," designed by Mr. Pargeter, of the Red House Glassworks, were exhibited by Mr. Pargeter. To the glass engraver, Mr. Northwood, we award a Silver Medal.

9. Messrs. Wright and Mansfield contributed several excellent examples of inlaid work of the English 18th-century style, in the manner of Chippendale, Adams, and Sheraton, as well as work enameled and decorated in the style of designs by Pergolesi. Awards of Bronze Medals were made to Mr. Thomas Hinton, the foreman workman, and to Mr. Victor Reich, the marquetry worker, and of Certificates to Messrs. Samuel Byrne, Charles Humphreys, and Thomas Miller, cabinetmakers, by whom the more important of these works were produced. The carved and gilt mirror-frames and girandoles in the style of the 18th-century English, and of Louis XV. French periods, especially three placed over the sideboard, were noted for superior workmanship, the carving being done by Mr. John R. Wingfield.

10. The modelling of the relief ornament carved by many hands, in a deep red mahogany mantle-piece and cabinet exhibited by Messrs. Collinson and Lock, was particularly good, and we award a Silver Medal to Mr. Webb, the modeller, for this and for many other specimens exhibited. His design for metal sconces was distinguished for richness in arrangement of conventional foliage, well grouped and modelled with good effect of low relief and harmony in flowing lines. The metal-worker who wrought this design in brass is Mr. Singer, to whom we award a Bronze Medal. Of a different style, but of much excellence, the design being by Mr. Lock, the modelling by Mr. Webb, and the actual metal-work by Mr. G. Price, was a mirror frame of repoussé oxydised silver. We award a Bronze Medal to Mr. G. Price for his metal working. The whole of the collection of furniture exhibited by Messrs. Collinson and Lock was noticeable for the completeness of workmanship throughout.

11. Some wrought-iron by Mr. Sidney Phelps, of Sidney Sussex College, Cambridge, deserves mention, especially the panel for a balcony, which was of a good style of design, with interlacings of rod-iron and beaten leaves of plate iron. The figures in the small panels, of deep modelled relief in terra-cotta, designed and executed by Mr. G. Tinworth, are full of expressive action, and we consider that a Certificate should be awarded to this artist. We award a second Certificate to Mr. G. Tinworth, the designer of the large flattened circular bowl, executed in stoneware, and shown by Messrs. Doulton; and a Certificate to Mr. Edward Sears for his careful and clean painting in monochrome on two tiles, called respectively "A Saucy Companion" and "An Old Chickadee." We do not commend the skill displayed in two delicate carvings in lime-wood, the work of Mr. W. Perry. Two panels of painted glass, suitable for the decoration of a house or hall, representing "Art" and "Science," appealed to us to show a right appreciation of the application of coloured glass to windows, without detracting from its utility as a window through which light has to pass.

12. In Bay No. 9, containing articles exhibited by Messrs. Gregory and Co., the reproduction of an old English armchair, enriched with carved and turned rails, and

a little tea table, were highly finished in workmanship, and commendable for the lightness of their construction. We award a Bronze Medal to Mr. W. P. Collins, the designer of these articles. To the designer, Mr. T. W. Hay, of the woven hanging, for the drawing and arrangement of details, as well as for good harmony of colour, we propose to award a Certificate.

13. The well proportioned framework or walnut panelling, for the side of dining-room or hall, shown by Messrs. Johnstone, Jeanes and Co., in Bay No. 11, was excellent in design, but, in our opinion, the effect would have been better if simple wood panelling instead of tapestry had been used. As it was, it produced the impression of an open screen which had been filled up, rather than of a wall.

14. The carving of the students of the School of Wood Carving, South Kensington Museum, was meritorious; and the plaster executed by Miss Eleanor Rowe, of this school, showed good feeling for flow of line and the modelling of surfaces. It may be well to mention here that a principal aim of this school is to cultivate the production of wood-carving in a broad style, and at a cheap rate, similar to that used so largely for decorative purposes in the eighteenth century in this country. The works of this school are not, therefore, intended to compete with more expensive and more highly finished wood carvings.

15. We award a Silver Medal to Mr. R. Gleeson, for the suitable and graceful fan mounts, which he has designed and executed, especially that of ivory, mounted with Mahogany. The inlaid Aubusson wood table, the work of Mr. Thomas Jacob, gained the distinction of a Bronze Medal, for the beauty of the marquetry work.

16. In concluding our report upon this Exhibit on, we are of opinion that annual Exhibitions, at which are shown various classes of Fine Art applied to Industry, such as the one represented at the present Exhibition, might be usefully supplemented were designers for all sorts of handicrafts and manufactures to be encouraged to submit drawings and sketches of designs which have actually been carried out. A sect out was allotted for such drawings at the Paris Exhibition of 1878; and, in our opinion, much useful instruction and information might be gained from such an annual display of designs to the benefit of producers and consumers.

GEORGE GODWIN, F.R.S.
MONTAGUE GUEST, M.P.
EDWARD J. POYNTER, R.A.
ALAN S. COLE, Hon. Secy.

5th August, 1881.

LIST OF AWARDS.

SILVER MEDALS.

Mons. Solon, for olive-green tapestry, *after the style of Messrs. Almon*.
Mr. de Morgan, lustre plates.
Mr. Webb, modeller and designer Messrs. Collinson and Lock.

Mr. R. Gleeson, for carved fan mounts.
Mr. Northwood, for glass-cutting and engraving Mr. Pargeter.

BRONZE MEDALS.

Mr. H. S. Holz, for painted furniture Messrs. J. G. Crace and Son.
Mr. Vernon Barnard, designer of side of room (Messrs. Morant, Boyd, and Blanford).

Mr. J. R. Randall, furniture designs and design for fender Messrs. Howard and Co.)
Mr. Albert Reich, marquetry-worker (Messrs. Jackson and Graham).

Mr. H. Reich, marquetry worker of cabinet (Messrs. Morant, Boyd, and Blanford).

Mr. William Allwright, designer of rosewood chimney piece, inlaid with ivory, ebony, mother-of-pearl, Messrs. Jackson and Graham).

Mr. Baldwin, cabinet maker (Messrs. Jackson and Graham).

Mr. T. Hinton, foreman cabinet maker Messrs. Wright and Mansfield).

Mr. Victor Reich, marquetry-worker (Messrs. Wright and Mansfield).

Mr. Singer, for beaten brasswork (Messrs. Collinson and Lock).

Mr. G. Price, for beaten oxydised silver frame (Messrs. Collinson and Lock).

Mr. W. P. Collins, designs for furniture (Messrs. Gregory and Co.).

Mr. T. Jacob, for marquetry top to table.

CERTIFICATES.

Mr. Marchant, cabinet-maker (Messrs. Jackson and Graham).

Mr. C. Humphreys, cabinet-maker (Messrs. Wright and Mansfield).

Mr. T. Miller " " "

Mr. S. Byrne " " "

Mr. M. Anderson, carver (Messrs. Gillows).

Mr. T. W. Hay, designer of woven saken fabric for room decoration (Messrs. Gregory and Co.).

Mr. G. Tinworth, designer and modeller of flattened round bowl, shown by Messrs. Doulton.

Mr. Edward Sears, for painted tiles.

Miss Eleanor Rowe, for carved wood pilaster.

Mr. W. Perry, for carving in wood.

Mr. Sidney Phelps, wrought-iron work.

Mr. W. C. Codman, designer of panelling (Messrs. Johnstone and Jeanes).

EMPTAGE'S PATENT SIPHON-TRAP.

UNDER the old non-ventilation system, the U-trap was the only trap which could be relied upon to hold its seal, and, notwithstanding certain drawbacks, it had to be endured; in fact, it was "Hobson's Choice." Ventilation has brought to the front the plain round siphon-trap, which could not be relied upon under the old system, but which can now be used with safety.

The ordinary round U-trap is, however, owing to its particular shape, not to be relied upon, as, under some circumstances the seal is lost, and no amount of ventilation will remedy

this evil. To meet this difficulty, Emptage's patent siphon-trap has been designed, which, its inventor claims, has all the advantages of the U, combined with the security of the S.

SCHOOLS OF ART.

READING.—The annual distribution of prizes and certificates, in connection with the Reading Schools of Science and Art, took place at the town-hall on Monday week. The 20th annual report stated that there were instructed last year 130 pupils in art and 82 in science. At the May examinations in second grade art there were 130 attendances by 94 students: of these 37 passed in one or more subjects, ten winning eleven Queen's prizes. The local advanced art and the art class teachers' certificate examinations were attended by four students, two of whom were successful. Eleven works in the advanced, and 742 in the elementary section, were forwarded by 110 pupils to South Kensington for examination; the full grant was allowed on twelve students in the elementary, and on one in the advanced; lesser grants being made on the others. Six third-grade prizes were won by five pupils. Mr. Ernest B. Havell, national scholar at South Kensington from the Reading school, has been awarded two bronze medals for chalk drawing of figures from life and also from the antique; also two third-grade prizes. At the May examinations in science there were 22 first-class passes, 27 second-class and 22 failures. The work of the class was last year carried on under adverse circumstance but the new session had just been commenced in the noble premises erected in connection with the town-hall extension. In January next a technical school will be started, and there had recently been added classes in agriculture, and in modelling and painting on glass and china. An address was delivered, on scientific progress, by Sir James Anderson.

CHIPS.

The presentation portrait of Sir Philip Protheroe Smith, three Mayor of Truro, which was painted by Mr. Sydney Hodges, and was hung in this year's Academy exhibition, was formally handed over on Thursday week. By the request of Sir Philip it will be hung in the council-chamber of the town-hall.

The new boys' industrial school at Cockermonth, which has been erected from the designs of Mr. John A. Cory, of Carlisle, county surveyor for Cumberland, will be opened by the Home Secretary, Sir W. Vernon Harcourt, to-morrow (Saturday).

The parish-church of Whileskill, near Stroud, Gloucestershire, was reopened on Thursday week, after restoration from the plans of Mr. W. H. C. Fisher. A transept, vestry, and organ-chamber have been added, and the tower arch at west end thrown open, the vestry with gallery above which formerly encumbered this end being removed. The passages have been laid with tiles, and the flooring in the pews has been renewed. The total cost has been about £800.

The old parish-church at Lanivet, near Bodmin, is to receive an addition of a reredos composed of an artistic combination of Cornish serpentine and of coloured marbles and Beer stone. Under Mr. J. Piers St. Aubyn, the architect, Lanivet church was restored twenty years ago; but funds did not then admit of the erection of the reredos. Mr. Harry Hems, of Exeter, who has the work in hand, has promised to have it *in situ* by Christmas.

At the annual meeting of the Stourbridge School of Art, held last year, it was reported that the resignation of the master, Mr. Bowen, had been sent in and accepted.

LUKSHMI VILAS PALACE, FOR THE GUICOWAR OF BARODA.
—ST. NICHOLAS CHURCH, WELLS, NORFOLK.—HOUSE AT LEICESTER.—THE CHAPEL, BEAUMARIS CASTLE.—ARCHITECTURAL ASSOCIATION EXCURSION SKETCHES.

OUR LITHOGRAPHIC ILLUSTRATIONS

LUKSHMI VILAS PALACE FOR THE GUICOWAR OF BARODA.

The Lukshmi Palace, designed by the late Major C. Mant, R.E., F.R.I.B.A., and being built for H.H. Maharajah Sayjee Rao, Guicowar (or "Gackwar") of Baroda, who assumes power in December of this year, is to be faced with "Soongah" stone, a vitreous grey local sandstone backed with brick, and enriched with blue, red, and yellow trap in strings, columns, panels, &c. The hoods of windows and the domes will be in coloured tiles, or white marble with finials and ribs in gold. The central portion will be occupied by H.H. the Guicowar. To the right is the zenana for H.H.'s mother and wife; to the left is the durbar hall, a carriage porch being attached to each. The decoration of the durbar hall will be in fine plaster with marble columns and alabaster and marble panels, niches, &c., with a wooden screened gallery for ladies to view durbar. The better class of the private apartments and staircases will be enriched with marble columns, panels, &c., floors of tiles or marble. The flat terrace roof will be constructed of concrete on iron girders covered with asphalt. All verandah roofs will be of concrete on teak joists with asphalt covering. The woodwork throughout the building will be teak. The windows of durbar hall and all important rooms will be decorated with stained glass. The estimated cost of the palace is £200,000, and it is being built by contract with native labour. It is now about 10ft. above ground, and will probably be completed in four years. Rajah Sir T. Madava Row, K.C.S.I., Dewan of Baroda, has taken a warm interest in the palace design, in fact, he sanctioned the late Major Mant's employment on it.

ST. NICHOLAS CHURCH, WELLS-NEXT-THE-SEA, NORFOLK.

This church was struck by lightning and burnt down on the 3rd of August, 1879. It was a fine specimen of the 15th-century architecture of the county. The beautiful embellished oak roofs and the fine arcade were its chief features. On plan it consists of nave and side aisles which are continued north and south of the chancel and formed side chapels (now used as a vestry and organ-chamber), a large chancel, an elaborate south porch, and a western tower. The accompanying perspective drawing shows the interior looking east, and was exhibited in this year's Royal Academy. The whole church has been rebuilt and restored, where practicable, exactly like the old. The work has been successfully carried out by Mr. Samuel Paminter, of Braintree, Essex, the contractor, from plans and under the superintendence of Mr. Herbert J. Green, architect, of Norwich.

HOUSE AT LEICESTER.

The drawing which we publish to-day of a residence erected at Leicester for Mr. Joseph Harvey, solicitor, was exhibited in this year's Royal Academy. The architect is Mr. Stockdale Harrison, of Leicester, and the builder Mr. H. M. Hewitt, of Leicester.

THE CHAPEL, BEAUMARIS CASTLE.

BEAUMARIS CASTLE was built by Edward I., the date of its commencement being 1294, or about 12 years after the death of Llewellyn, and 10 years after the founding of Conway and Carnarvon Castles. Between those great fortresses it is exactly equidistant, and served as a connecting link. As a post of observation it was of great importance, as from its towers could be surveyed the opposite coast from Conway to Carnarvon, and the mountainous district inland, where Llewellyn had for years maintained himself against the English. There is an old account existing which describes the progress of the building in 1295, and mentions the carrying of the stone from Penmon in ships at the rate of 10d. a freight. It is nearly a square in plan, and has an outer wall with ten low circular towers. Round this wall ran a deep moat which was filled from the sea by a canal by which supplies were brought up to the castle walls in barges. The only entrance in the outer wall is on the side facing the sea, and was accessible by a drawbridge and portcullis. The walls of the main building are much higher and more massive, and have ten large circular towers, of which there is one at each angle, two on the north, and two on the south flank, (between which are the two entrances into the great quadrangle), and one on the west and one on the east side. In this latter tower, without any external features to distinguish it, is the chapel. It is reached by the narrow passage which traverses three sides of the quadrangle and crosses the chapel-porch through the small chambers on each side. In the porch there is a wide moulded archway opening into the quadrangle at a considerable height above the ground. This archway, having its threshold level with the floor, might be supposed to have been a direct entrance from the quadrangle into the chapel; but the absence of any means of ascending to it, and all traces of such if there formerly existed any, render the supposition at least improbable. Opposite this arch is the double doorway of the chapel, one opening of which has for some unaccountable reason been walled up. The chapel is very dark; the windows are so narrow as scarcely to allow a man to pass through them, and are splayed upwards from the inside, an arrangement which, on account of the enormous thickness of the walls, secured a better light and increased their height from the ground outside—an advantage from a military point of view. The small chambers contained in the thickness of the wall on either side, and reached from the passage by a flight of steps, were private oratories; the jumbs of the windows which look into the chapel are splayed so that the occupants could see the altar. The ante-chapels on either side of the porch are pointed out to visitors by the castle keepers as "confessionals," an idea, perhaps, suggested to their fertile imaginations by the narrow openings into the chapel. Here and there the mouldings have been defaced and a few stones loosened; the floor is broken and uneven, only traces of the two steps shown on the drawings remaining, and the stone bench on

either side has been partially destroyed; but with these not surprising exceptions, the chapel is in a perfect state of preservation. It would seem, from an ancient record, that in 1344 the chapel-tower was still unfinished, and that an estimate was made in that year that it would take £128 to complete it, but whether it was ever finished or not there are no means of ascertaining. Considering its size and importance, Beaumaris Castle has little history, what it does possess being comparatively uninteresting. The chapel is now the only apartment of any size that remains intact, for which circumstance, to a great extent, may be thanked the zealous builders of last century who used the massive walls as a quarry, and removed the timbers of the floors and roofs, giving to the building its present low and unimposing appearance.—JAMES F. SINNOTT.

SKETCHES FROM WORCESTERSHIRE.

The interesting sheet of sketches which we have lithographed to-day are from a series made during the Architectural Association Excursion by Mr. John Bilson. Most of the examples shown have already been referred to in our description of the visits then made. The Salwarpe Court House Bay and old Timbered House next the "Swan" in High-street, Tewkesbury, are illustrated in Habershon's work on "Half Timber Buildings." A comparison of the two renderings, besides showing that the examples drawn have suffered during the last twenty-five years but very little change; indicate a decided improvement in architectural draughtsmanship, chiefly in the direction of technical accuracy. The stone gateway from Norton Manor, shown by the small sketch in the centre of our sheet, is a charming example both of general design and detail.

CHIPS.

On Monday, a petition was filed in the Walsall Bankruptcy-court, on behalf of Daniel Moore, builder and contractor, Stafford-street, in the same town, with liabilities amounting to £19,500, and assets not ascertained. Messrs. Cotterell and Carter, Walsall, are the solicitors acting in the matter.

We understand that the walls of the Society of Engineers' Meeting Hall, in Westminster Chambers, are covered with drawings of various recently-erected iron roofs, in illustration of Mr. Arthur T. Walmisley's paper, which is to be discussed at their next meeting on November 7th.

At a meeting of the committee for the completion of St. Paul's, Truro, held last week, it was decided to instruct the architect, Mr. J. D. Sedding, of London, to prepare working drawings for the first section of the scheme, including the extension of chancel, and erection of chancel aisles, parish-room, and vestries.

A loan art treasures exhibition was opened at Goolle last week, and has been well attended.

A vestry meeting was held at St. Saviour's, Larkhall, near Bath, on Thursday week, when plans by Mr. C. E. Davis, architect, of Bath, were accepted for the extension of the chancel of church by 22ft., the reseating of the nave, the removal of west gallery, and opening out of the tower.

The Countess of Jersey laid, on Thursday week, the foundation-stone of a new mission church of St. Thomas, at Pantyrrhol, Briton Ferry, near Cardiff. The building will be erected of native rubble stone, with Bath stone dressings, and will have an open-timber roof and seats of stained deal. The nave will be 48ft. by 24ft., and the chancel 17ft. by 15ft.; accommodation being provided for 150 persons. Mr. H. Francis Clarke, of Briton Ferry, is the honorary architect; and the tender of Mr. Isaac George has been accepted for the work at £312.

The will of the late Alderman Sir William Anderson Rose, of Upper Thames-street and Tooting, has been proved, the value of the personal estate exceeding £51,000.

At the Cambridgeshire quarter sessions on Monday, plans by Mr. W. M. Fawcett, of Cambridge, were adopted, for alterations to the grand jury-room at the Guildhall in that town.

A stained-glass window was last week uncovered at the east end of north aisle in Epworth parish-church. The subject is "Christ, the Sower." The glass was supplied by Mr. W. H. Constable, of Cambridge, and the masonry and fixing carried out by Mr. F. Graat, mason, Epworth.

The Helston town council elected on Tuesday week Mr. W. Cates as borough surveyor, in succession to the late Mr. W. Eva.

Building Intelligence.

ASTON.—The foundation-stone of the new grammar-school, in Albert-road, Aston, was laid on Wednesday afternoon. The school will accommodate 500 scholars—250 boys and 250 girls—and has been designed by Mr. J. A. Chatwin, architect. The site faces Albert and Frederick-roads, near the Victoria-road entrance to Aston Park. On one side will be erected the boys' block, and the girls' on the other, the playgrounds and caretakers' house being between the two. The plan of each block is similar, and provides nine classrooms (32ft. by 22ft.), an assembly-hall (70ft. by 24ft., with open-timbered roof), a room for teachers, lavatories, and a room for drying clothes. The class-rooms will be arranged in two floors, the upper floor being approached by a commodious flight of stone stairs. The external elevation will be in the Gothic style, carried out in red brick with dressings of terra-cotta. An oak ventilating turret will be constructed over the assembly hall, and the caretaker's house will be so arranged as to command a view and give ready access to both playgrounds. The schools will be erected by Mr. R. N. Smith, of the Crescent, Birmingham.

FULMESTON.—The new church at Fulmeston, Norfolk, consecrated on Oct. 19, is erected in the middle of the village, and is intended to supersede the old church, which is very inconveniently situated, and which will, for the future, be used only for the burial service for funerals in the old churchyard. The new church consists of a nave and chancel, a south aisle with three arches opening into the nave, a vestry or chancel-aisle also on the south side, and shut off from the aisle and chancel by ornamental screens. On the north side there is a porch. The style adapted is Late 14th-century. The walls are built of flint with Bath and Ancaster stone dressings, and internally they are lined with red bricks, with patterns of white bricks. The roofs are open-timber roofs, that of the chancel being panelled and boarded. At the east-end there is a one reredos, with columns of polished alabaster. The pulpit is also of stone, and has an alabaster cornice and columns. The font is an old 13th-century base and columns, with the bowl renewed in accordance with the old: until now it has stood for many years in the graveyard at Croxton Chapel, Norfolk. The outer doorway to the porch is also old, and was brought from the old church at Fulmeston and reused. The seats in the nave and chancel are new (oak being used in the chancel). Those in the aisle were brought out of Croxton Chapel and refixed. The altar-table and rail were also brought from Fulmeston Old Church. The whole of the works have been executed by Messrs. Cornish and Gaymer, of North Walsham, Norfolk, under the direction of the architect, Mr. Wm. Bassett Smith, John-street, Adelphi, London.

HUDDERSFIELD.—The memorial-stone of the new Technical School and Mechanics' Institution at Huddersfield, was laid on Wednesday week. The central feature of the ground-floor plan is a large weaving-shed 68ft. 6in. by 41ft. 6in., for elementary instructions in weaving and designing, with a smaller one beyond for more advanced students. The first floor of the building, approached by these staircases, will contain mechanical, modelling, and physical science classrooms, and a large library, in connection with the reading-room and senior elementary classrooms. The second floor comprises the School of Art. The other wing of the building is arranged for elementary junior classrooms, and a retiring-room from the platform of a large lecture-hall occupying the majority of the Queen-street South front, 68ft. 6in. long by 36ft. 6in. wide, and 27ft. high. The building is designed in rather Late Geometric Gothic. The main walls will be built in extra hammer-dressed wallstone, with moulded ashlar dressings and double moulded mullioned windows, filled in the upper part with handsome tracery for the larger lights of the gabled portions of the building, with pinnacles on the angles. High-pitched roofs will cover the portion facing Queen-street South, with a large fleche containing a Boyle's patent ventilator, rising to a height of 34ft. to the top of the iron finial above the ridge, in addition to smaller louvred dormer ventilators, suitably placed, which serve to ventilate the

large hall and other parts. The slating will be green Westmoreland, with ornamental red tile ridgings and finials. The building will have a frontage to Queen-street South of 105ft., the returns to Princess and Page-streets being 135 each, and containing an area of about 1,600 square yards. The cost will be £12,000. Mr. Edward Hughes, F.R.I.B.A., has designed the buildings, which are being carried out under his supervision, Mr. Bates, of Nottingham, being the clerk of works.

LEEK.—West-street Wesleyan Schools, Leek, were opened on Monday after extensive alterations and improvements. There are now in all twenty-six classrooms for separate teachings, as against ten on the former arrangements. The larger ones are about 24ft. by 20ft., and the rest about 15ft. by 13ft. This increase will relieve the large room of the class-teaching on Sundays, and it will be used on that day for general assemblages of the scholars. The classrooms are connected with the large rooms by a system of electric bells, and the large rooms communicate similarly with each other. The additional buildings include also an infants' schoolroom, 21ft. by 33ft. The works have been carried out to the plans and under the superintendence of Messrs. William Sugden and Son, architects, of Leek. The contractor was Mr. C. S. Bromage.

NOTTINGHAM.—St. Ann's Church, Nottingham, has been enlarged by the addition of a gabled aisle, which runs by the side of the old north aisle, and it now forms a double aisle. The pulpit has been removed to the north reposit of nave arcade. The new work is of Bulwell stone for the walls, with Bath-stone dressings. The arcade has circular columns and flowered capitals, the arches being double chamfered. The roofs are open-timbered, each pair of rafters being trussed; the whole of the woodwork is of red deal, stained and varnished. Mr. Brown, of Birmingham, supplied the gasfittings. The contractor for the whole of the works was Mr. Henry Vickers, of Nottingham, and the architect was Mr. Robert C. Clarke, Journal Chambers, Nottingham. The additional accommodation gained is about 200 adult seats.

PROPOSED NEW ASYLUM, PARC GWILT, GLAM.—At the Michaelmas Quarter Sessions for Glamorganshire, held on Thursday, Col. Tuberville, on behalf of the asylum committee, reported that it having been decided to erect a new asylum at Parc Gwilt to accommodate 700 patients, the committee communicated with all the large asylums as to whom they should employ as architect. As a result they had engaged Messrs. Giles and Gough, of Craven-street, Strand, W.C., who undertook for £350 to prepare plans which should be the property of the committee whether they were used or not. The plans which were sent in three weeks ago were now upon the table. The chairman moved that the plans be considered at the next session, and that in the mean time a committee of the court be appointed to consider them. Mr. Gilbertson, in seconding the motion, asked for a thorough investigation of the plans, as the cost of the new asylum was likely to reach £120,000. Mr. Llewelyn asked whether the committee could obtain other plans in competition with those privately selected, to which the chairman replied that after the committee had reported, it would be the duty of the general court of quarter sessions to seek new plans or new architects. The motion was then carried, and a committee of a dozen members appointed.

WESTON BEGGARD.—The parish-church of Weston Beggard, Hereford, was reopened on October 13th, after restoration, at a cost of £1,200. The work has been carried out from the designs of Mr. Nicholson, the diocesan architect. The restoration comprises the rebuilding of the south wall and nave, and the rebuilding of the east wall, containing the chancel arch. New windows have been put in in the nave, and a new roof of open-timbered work, with carved oak bosses, put over the nave and the chancel. All the roofs are boarded and felt-covered, and encased with Broseley tiles outside. The portion of the chancel-roof over the sacristy has had an under-ceiling of moulded and ribbed panels put in, ornamented with carvings in oak, and moulded and battlemented cornices are run round the interior of the roofs. New windows have also been placed in the chancel. The gables of the church have been newly copped, and have had new crosses put upon them. All

the old masonry everywhere has been thoroughly restored and repointed. The restoration of the porch consists of restoring the masonry, resetting the arch, and putting a new open-timbered roof, with new copings. A new cross has also been placed over the porch. The walls of the nave and tower are laid with plain ornamental tiles, and a richer description of tile, of a very beautiful pattern, has been used in the chancel; these have been supplied from the encaustic tile works of Mr. Godwin, at Withington. New wickets, made of oak, have been placed at each entrance to the church. The stone dressings of the windows are of Luston and Ombersley stone, and the south wall is built entirely of local stone. The chancel steps are of Forest stone. The work has been carried out by Mr. W. Cullis, builder.

COMPETITIONS.

BIRKENHEAD TOWN-HALL.—The instructions to architects in this competition, have just been issued by the town-council. Following the Glasgow example, there will be two divisions in the competition, a preliminary one of sketch designs, open to all architects, and a final limited one. Mr. Charles Barry, of Westminster, has been appointed referee in both competitions, and will advise the council on the preliminary designs, selecting from them five, whose authors will be invited to compete in the final competition. The referee will also advise the council as to the order of merit of the second set of five designs, and as to the probable sufficiency of their estimates. In order to obviate the possibility of the sketch designs lodged in the preliminary competition being made use of by the competitors invited to take part in the final competition, such sketch designs will not be allowed to be seen by any one except the council and referee, and will be retained until the final competitive designs have been sent in. In the preliminary competition the drawings must be to a scale of 16in. to the inch, and will consist of plans of the basement, principal, first and second floors; elevations of each of the four fronts; a longitudinal and transverse section, a perspective view, and a block plan of the building filled in on the lithographed plan of site supplied to each competitor. All the drawings of the elevations must be executed only in pen and ink without colour of any sort, except (at the option of the competitors) a flat tint of Indian ink on the door and window-openings and on the roofs. The walls in plans and sections are to be coloured only in Indian ink, and the dimensions of each room are to be figured on the plans. No framed or glazed drawings will be received, and all geometrical drawings are to be on uniform stretcher mounts, 30in. by 22in. Designs not exhibited by "at least" as many drawings as specified, and to these scales will be excluded. The designs and envelopes, containing authors' names, will be numbered by the town-clerk in the order of their receipt, and will be known only by such numbers. Each of the final competitors will be paid £75 towards his expenses, provided he comply with the conditions for the final competition to be issued hereafter. The author of the design placed first in the final competition will be employed to execute the building as architect, unless insuperable obstacles may exist, of which the town-council, with the advice of the referee, shall be sole judges; he will be paid the usual commission of five per cent. on the work, as well as travelling expenses in visiting and directing the works, should he reside more than 35 miles from Birkenhead. The cost of the building, exclusive of internal fittings, furnishing, and decoration, is not to exceed £42,000. Stringent regulations provide against canvassing of the town-council or the referee, and the publication of drawings, photographs, or written or printed statements prior to the issue of the award in the final competition.

EAST LOOE CHURCH COMPETITION.—Thirty-three designs have been sent in for the proposed rebuilding of this Cornish church. They emanate from as many architects hailing from Penzance to Aberdeen. The 29th ult. was the last receiving day. Since then the committee have selected four. These are to be sent to a well-known London architect for adjudication.

OLDHAM FREE LIBRARY AND MUSEUM.—In this competition the Corporation have selected the design marked "F.S.A.," submitted by Mr.

Thomas Mitchell, F.R.I.B.A., of Oldham and Manchester, for the first premium, £100, and the design marked "Practical" (Messrs. Wright and Rawcliffe, of Burnley) for the second place, £50. There are 26 competitors altogether, and the limit of cost was £8,000. The permitted design follows the general arrangement indicated in the instructions, and shows, on the ground-floor, beyond the entrance hall, a library, placed centrally between reference-room and periodical-room, with floor on a level of 18in. above these apartments, and the spaces between are filled by screens, glazed with etched tinted glass, allowing of supervision. Projecting bays on either side of library form book windows and booking desk, and round the upper part of room is a book gallery. The officials will enter by a separate staircase from basement. The main reading-rooms are continuous with library. The chief or Union-street front of premises is occupied by central entrance, and on left the ladies' reading-room (although in practice "F.S.A.") says such an adjunct is not usually found a necessary or an economical feature), and on right a committee or curator's room. On the first floor are a museum and art-gallery, each 86ft. by 25ft., with a connecting hall, 33ft. by 20ft., all top-lighted by continuous lanterns. To improve the lighting of the upper casement side walls, the author provides short side lights, just below the ceiling, and has so arranged the overhanging of roofs as to prevent the admission through them of direct light. The basement shows a technological museum, patent-library, stores, curator's rooms and offices. The elevation shows a simple form of Domestic Gothic, with square-headed transomed and mullioned windows; no towers or pinnacles are proposed, but over the central doorway is a circular moulded head, with carved tympanum, and above it, in the first floor of gable, a projecting oriel. The suggested materials are Halifax pierpoints with ashlar dressings. The second permitted design is Italian in character, the principal feature being the roofing, which consists, up to Union-street, of three lozenge-shaped Mansards, the largest of which is in the centre. The effect in the front elevation is not pleasing, but it looks very well in perspective. Among other more elaborate but less suitable designs may be mentioned, "Canton," "Derby," and "Q.E.D.," neither of which could be carried out for the sum specified. A very clever water-colour in sepia is contributed by "Sepia," but the design is not suited for the purpose of the building. The sealed envelopes containing competitors' mottoes and names were opened by the town council on Wednesday.

CHIPS.

A new Bible Christian chapel at Probus, Cornwall, was opened last week. It will seat 150 persons, and was built by Messrs. Gerrans, of Tregony.

The parish-church of Merrow was reopened by the Bishop of Winchester on Tuesday week. A north aisle and a vestry have been added to the nave, the former providing accommodation for 100 persons. The north porch has been rebuilt, and a new east window put into the chancel, which has been internally decorated in Thirteenth-century style by Mr. R. Smith, of Winchester. Mr. A. W. Blomfield, M.A., of London, was the architect, and Messrs. W. Smith and Sons, of Guildford, were the builders.

One of the latest companies floated proposes to girdle the metropolis with a boulevard after the Parisian fashion—a broad roadway, with a circumference of 25 miles, planted with trees, and including tramways. Blackwall, Brixton, Shepherd's Bush, and Hampstead are the boundaries the boulevard would touch. The plans have been drawn and issued.

New municipal buildings at Llankeston, including a council-chamber and two committee-rooms, and a castellated tower, are approaching completion, and will be opened during the next fortnight.

The parish-church of Carlton-in-Cleveland, near Stokesley, was entirely destroyed by fire on Wednesday week. It is believed to be the action of an incendiary.

Mr. Bat Smith, of Spanish Camp, Texas, has patented an improved composition for preserving wood, consisting of eight parts of coal-tar, one part of crude carbolic acid, and three-fourths part of crude pyroligneous acid, mixed and heated, but not permitted to boil. The wood to be treated is placed in a vessel filled with the compound, where it remains until saturated.

"To a practical man with a taste for mechanics, and the bumps of construction fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *Engineering*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two pence of all newsmen, or post free 2d—31, Tavistock Street, Covent Garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 49c. gold); To France or Belgium, £1 6s. 6d. (or 3fr. 30c.); To India (via Bimlasi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few double volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—E. and Co.—R. G.—C. B. K.—C. C.—J. B.—E. J. G.—P. E. Co.—J. C.—R. and R.—W. G.—A. H. I. Co.—R. F. C. Co.—N. F. L. Co.—A. M.—T. B. and Son.—M. J. C.—C. of H.—H. B. and E.—W. K. and P.—J. C. E.

"BUILDING NEWS" DESIGNING CLUB.

ERNEST, J. B. E. H., and OTHERS. (Due notice will be given of our future arrangements.)

Correspondence.

THE INDIAN PUBLIC WORKS DEPARTMENT.

To the Editor of the BUILDING NEWS.

SIR,—Your excellent article in the number for 21st October referred only to the recent reprint of Sir Andrew Clarke's minute under review. You did not touch upon the reductions which were the outcome of this minute, but which would never have taken place to the extent they did had he remained at the head of affairs. He suggested the reduction of about 100 men, and proposed a very good scale of pension for those who should be retired. The state of things which necessitated such changes was entirely due to the action of the Government of India. They had had resented to them, time after time, the inadequacy of the pension rules to clear off incompetent or worn-out men.

In 1879, the Government of India Council sent out specially appointed men, on a five years' contract. At the end of that time they should have either dispensed with the services of these men, or entered into a further agreement for a definite term of years; but they preferred to keep them on, and thus blocked the promotion of juniors. A remonstrance was sent up, and I am led to believe that the Government of India issued an intimation that the former should be kept on the supernumerary list. They did not do so, however, and continued to them all the privileges which had

been uninterruptedly enjoyed by the Department until 1879.

In consequence of the Afghan War, however, there was a great outcry for reduction, and, of course the I.R.W. must be operated on, and nearly 300 men were politely, but in very plain language, informed that if they sent in their resignations by the 31st December, 1879, they would receive the bonus and pension awarded. About 329 men were thus got rid of; possibly the odd 29 went voluntarily, but by far the larger majority sent in their resignations under pressure; and in some cases of very considerable pressure, too. Amongst these were many so-called "Stanley Engineers," whom Sir Andrew Clarke distinctly states could not be made to retire, as they were covenant men, and entitled to all the rules of pension, &c., of the Department.

You will thus see that injustice was first done to the Department by bringing in outsiders and placing them on the establishment rolls instead of on a supernumerary list, thus blocking the promotion of the juniors. A further injustice was then done to the Department as a whole by discharging such a large number compulsorily.

There are also a number of military officers in the Department, a few belonging to the Staff Corps, but by far the larger number to the Royal Engineers. Of the latter there are two classes—the old local army men, now borne on the Imperial list, and the Imperial R.E.'s; the former of the two entered the service with a view to being employed in the Public Works Department, or its then equivalent, and had certain rights which prevented their being turned out. Not so an Imperial Royal Engineer, however; he had only to take his turn of foreign service, and might have been relegated to military duty without interfering with his prescriptive rights. This course was not taken, however; but, as the *Builder* says, a two-years' holiday was given to a limited number on furlough pay, but counting for pension. This boon, had it been extended to the civil members, would have been eagerly availed of by many.

The fact, however, is that the present secretary to the Government of India in the Public Works Department took advantage of a necessary reduction to work for the benefit of his own corps, as he found that amongst the civil members of the department there was a large body growing up who would eventually come in for the higher appointments in the department, and that this growth must be nipped in the bud by reducing the numerical strength of the civil element. In fact, so great is his antipathy to the civil branch that in a report signed by him, which was published, however, without his sanction, there actually appeared a proposal to do away with it altogether, and to substitute Royal Engineers and natives entirely.

From the above you will see that the known discontent in the department results entirely from the action of Government; first, because the Government never keep the promises made, and are so constantly reorganising the department that the members never feel their prospects safe for one day; and second, because the civil body is entirely unrepresented, and in the hands of Royal Engineers, who invariably "reorganise" for the benefit of their own corps.

Until, therefore, the Government of India take steps to improve pension rules, and thus insure an even flow of promotion and guarantee that their interests are properly represented by men of their own body, civilians will not work with that amount of vigour which is necessary for the good of the department work, and the sooner that Government recognise this, the better for all concerned. In their discontent, however, Sir A. Clarke emphasises the fact that he has seen

NO DISLOYALTY TO GOVERNMENT.

FREEMASONRY AND THE "SATURDAY REVIEW."

SIR,—I thank "Veritas" for his letter, and regret that I cannot spare the time, nor even you the space, to allow me to write fully in answer.

"Veritas" quotes some good names of writers on Freemasonry, the true history of which has yet to be written.

I must admit that it is difficult to prove that lodges of speculative Masons existed before 1717, but there were certainly lodges of operative masons in the middle ages, and the connection with them of the Knight Templars can be easily explained.

Whether Freemasonry be ancient or modern, it is now a powerful society doing a great work, and is quite undeserving of the absurd and untruthful statements made by the Papal press.—I am, &c.,
KNIGHT TEMPLAR.

PRACTICAL EXPERIMENTS WITH CLOSET-TRAPS.

SIR,—I have always maintained that a round siphon-trap, to be safe, must be ventilated independently of the soil-pipe vent, which should also be full bore. I have not the least doubt, therefore, that under conditions described by Mr. Davies, Beard and Dent's ∇ -trap did lose its seal: it would have done so had the soil-pipe been only 5ft. instead of 45ft. long, the head vent being powerless in the matter; but, if Mr. D. will add to his trap B a 2in. independent vent-pipe, he will find that he cannot untrap it by means of his plug, although he will most probably do so with a pail of water, the effect of the two kinds of flushes upon the seal being very different.

Mr. Davies says, "This experiment proves at once that the ∇ -trap is unsafe for a valve-closet." Now, here Mr. D. is wrong. Having carefully watched the effect of flushes from a Underhay valve-closet upon the seal of a round siphon-trap fully ventilated, and having also tried a great many experiments with apparatuses, fitted up for the purpose similar to those shown upon page 540, which very nearly represent the action of a valve, I find that beneath a valve-closet is the safest place to fix a round ∇ -trap, and that it will there hold its seal secure; it is, however, when fitted in connection with other apparatuses very insecure.—I am, &c.,

DANIEL EMPTAGE, S.E.

Dane Hill Sanitary Works, Margate, Oct. 22.

P.S.—Mr. Davies has now a capital opportunity, in connection with his 50ft. scaffolding arrangement, to verify or otherwise his statement on page 356, that the rocking motion caused by draught up and down the soil-pipe acted upon the seals of siphon-traps in such a way that they became untrapped, and no doubt he will, when satisfied upon the point, reply to my letter upon the subject on page 408.

SIR,—In the above experiments, as described by Mr. P. J. Davies on p. 510 of your journal, it seems to me that, although the experiment on the ∇ -trap, as compared with that on the ∇ -trap, was relatively fair, yet the failure of the ∇ -trap can be accounted for as follows:—The cap G, Fig. 1, being taken off, and the plug removed from the right hand basin, Fig. 1, the rush of the water through the ∇ -trap would completely charge the outlet, as shown by K, Fig. 3, and the trap would thus lack the necessary ventilation to counteract its siphonic action; again, even though the outlet were not so charged, would not the air, drawn from the top of soil-pipe, follow the course of the water, to fill up the vacuum thus caused, and instead of increasing the atmospheric pressure at the outlet of the ∇ -trap, tend to draw from it and aid siphoning?

Now, it would be interesting to know whether the result would have been the same had a special ventilating pipe 1½in. diameter been carried from the apex of the ∇ -trap in an upward direction, and connected to the soil-pipe below the top, for the purpose of supplying a weight of air on the outlet side of the trap to equivoice that on the inlet or basin side—a point in connection with this form of trap which, in his fourth lecture, Mr. Hellyer considered so essential, and which is confirmed by the experiments of Dr. Lissauer (see p. 384). Mr. Davies mentions that when the cap G, Fig. 1, was replaced on the top of the soil-pipe, the action was precisely the same: this would seem to show that when the cap G was removed, in the first experiment, that the air supplied did not aid the ∇ -trap in preventing siphoning, and that what the trap needed was separate ventilation, as just mentioned. The experiment in a similar manner on the ∇ -trap did not cause it to siphon or wave out; but this is not surprising, as it is admitted its fault (if any) does not consist in its liability to siphoning.

The trap L, Fig. 3, siphoning out when B basin, Fig. 1, was discharged is a very likely occurrence, as it could scarcely be said to be ventilated, although the cap G was off, and to prevent its siphoning required the special ventilating-pipe from the trap to the soil-pipe, or, as Mr. Hellyer recommends, by a separate 1½in. pipe carried up above the trap B, Fig. 1, and then connected to soil-pipe, or left open in this case.

Mr. Davies says, as regards the consequences of the experiments, that nothing in them is new to him. In his account of the experiment with the Eclipse trap, he says:—"The water rushed through and left the water-seal broken ½in. below the dip." Now on referring to his former description of this trap, p. 354, I read, "This trap is a good and useful one." The two accounts certainly do not correspond, and I am at a loss to know how it can

have two such good qualities and yet be liable to have the water-seal destroyed at the first rush of water. Is it that this is new to Mr. Davies, or that the trap lacks something, and that, probably, special ventilation?

I presume that the ∇ -trap used in the experiment A, Fig. 1, Pullen's, was made according to Mr. Davies' model scale.

The outcome of this long-sustained and animated discussion cannot but be beneficial to both plumbers and interested outsiders, and the best thanks are due for this to Mr. Hellyer in the first instance.

As one of the outsiders, I write simply for information.—I am, &c.,
W. U. O.

WATER-TRAPS AND SIPHONS.

SIR,—In reply to Mr. Buchan's letter, let me tell that gentleman his patent being dated 1875, the £ 00 stamp duty has to be paid next year. Now, of course, it will answer Mr. Buchan's purpose very well to entice me into argument, and find out whether his patent is worth anything or not; however, I am not disposed to be any man's patent agent for nothing; but as he is very anxious that the winner of the palm should bear it, I quote the following from an old book many years anterior to the date of his patent:—"I have the above cesspool or receiver placed or formed so as the bottom of the receiver may be some distance below the bottom of the sewers, so as the sewerage or heavy matter may have a fall. This fall causes an eddy or irritation of heavy matters, which will continually be in motion under the mouth of the siphon; this motion will cause the stone, sewage, or other matter to pass off in the siphon." Farther than this, I have seen a drawing with precisely the same action as that in Mr. Buchan's trap, and that is dated nearly ten years earlier.

In reply to the query whether I have drawn my trap (Fig. 100) upside down to make it appear like his (Fig. 101), I must express an opinion that it is a very great piece of audacity on his part, as my patent is dated 1876, exactly as shown in my drawing, whereas his half ball-trap is dated 1875; so that if anybody is a copyist, it is himself.

With reference to Jennings' trap, the ball is quite independent of the water, as it rests on the aperture S, as shown in Fig. 103. In conclusion, I cannot help thinking that Mr. Buchan is not a careful reader, and that he is simply asking me for information, and as my time is fully employed, I must decline to answer any more of his letters unless privately, as even this, his last letter, is only in the interest of his own trap, and by this answer I have shown plainly that he need not be too certain that he is entitled to the patent at all.—I am, &c.,

P. J. DAVIES, Hon. Mem. A.S.P.

CHIPS.

A new mission-house is about to be built at Sowerby Bridge, near Halifax. The contract for masonry has been let to Messrs. George Sutcliffe and Son; that for joinery to Mr. George Hoyle, of Millbank, and that for plumbing, &c., to Mr. J. Stafford, Sowerby Bridge.

It is reported that the Sultan has given orders for the remains of the Temple at Jerusalem to be restored, and the surrounding place to be cleared of all rubbish. On that place stands the Mosque of Omar, the revenue of which has always been forwarded to Constantinople; but for the future it is to be appropriated for the above-mentioned purpose.

The rural sanitary authority of the Barnsley Union, at their last meeting, approved of plans prepared by Messrs. Dixon and Moxon, architects, Barnsley, for new cemetery, chapels, curator's house, and the laying out of four acres of land in Hunningley-lane for burial purposes for the parish of Ardsley, near Barnsley, the outlay on which will be about £2,400. The same architects have also just commenced a similar work for the Craggstone burial-board, which is to cost about £1,800, and it is expected to be completed in May next.

Mr. Lewis Angell, engineer and surveyor to the West Ham Local Board, has been awarded a *honorarium* of 200 guineas, with salary increased to £800 per annum, without any interference with his private practice. Mr. Angell declined £1,000 per annum with limitation to consultative practice.

One hundred and forty-nine applications were received for the post of surveyor to the city of Hereford. The committee selected the following five gentlemen to attend the special meeting of the council, held on Monday, the 24th inst.: Messrs. J. Parker, Bridgwater, borough surveyor; T. Tyler, Hereford, assistant surveyor; A. Holt, Beverley, borough surveyor; E. Kenworthy, Handsworth, surveyor to local board; W. L. Franklin, Reading, assistant surveyor—when Mr. Parker was elected. The salary is £250 per annum.

Intercommunication.

QUESTIONS.

[6738].—Working and Detail Drawings.—Never in the course of my employment having an opportunity of learning or studying working and detail drawings connected with the building trades, shall be obliged if some reader of the *Building News* will inform me if there are any books published on the subject that would teach me?—JOURNEYMAN PLASTERER.

[6739].—Window Tracery.—Are there any cheap books on tracery? If so, will someone kindly give address of publisher and price of book?—E. C.

[6740].—Concrete Houses.—I should be much obliged for information or hints on this subject. I want the floors and staircases (as well as the walls) to be of concrete throughout, and self supporting. Some years ago I prepared for an architect whom I was then assisting, designs for miners' cottages, in which the floors were of concrete, some four or five inches thick, and without iron joists in them, and he assured me they would be perfectly safe, but I did not see the buildings, and have had no other acquaintance with this kind of work. I should like to be told what is a fair thickness for walls, floors, and staircases, and how the latter are best constructed; also the best materials, and the cost in comparison with brick and wood in a country where gravel is fairly cheap. Will cement concrete stand heat, or must chimney openings be lined with brick? I should finish the stairs in cement, and form architraves and skirting of the same material, building in, I suppose, wood blocks for fixing locks, hinges, &c. The floors would be covered with parquet, or with pitch-pine strips laid in patterns.—D. LEE ET DECORUM.

[6741].—Mounting Engravings, Tracings, &c.—I have for years past been collecting the most choice plates from *Art Journal*, *Illustrated London News*, *Illustrated Dramatic News*, *Graphic*, *Punch*, *Vanity Fair*, &c., &c. (the *Building News* plates I bind). It was my intention, long ere this, to properly catalogue them, and put them in a scrap book or scrap-books, but upon looking through them, I find I have so many, in fact, I have created a "Frankenstein," and am frightened; yet, on the other hand, they are useless in their present state; perhaps some correspondent who may have "gone in" for something of the kind could give me the benefit of his advice, as to the best and quickest way of putting them into a scrap book, and whether there is any kind of scrap-book made for this sort of thing. With respect to tracings, which are purely architectural, if I use gum, I fear it will be an awful job. Is stretch any good? Having never done anything of the kind before, I am somewhat at a loss. How about paste, and also should I paste them all over (some are very large), or only round the sides, in case I use paste? Perhaps another collector will come to the rescue and oblige.—HAMILTON IS A FIX.

[6742].—Compressibility of Air in Sewers.—Suppose an air-tight pipe sewer, 2½in. diam., 1000 yards long, and having 2½in. fall from end to end. The top end is completely covered and sealed by water, which is occasionally discharged into the pipe-sewer, by opening a sluice, to flush. How long time would elapse, and how far would the water travel in the pipe before the air be disturbed at the lower or debouching end of the pipe-sewer, which is always open? Can this be calculated? Suppose the same pipe, not air-tight, say it is built of bricks and mortar, and has many branch sewers and drains from dwellings running into it, would not the pressure of the flushing-water—which always seals the whole diam. of the upper end of the pipe, while the lower or debouching end is always open—free air through untrapped openings and weak traps for a given time, and on subsiding draw air into the pipe? Suppose the same pipe was not covered or sealed by water when being flushed, and the pipe running half full for a time, how would this act upon the air in the pipe-sewer, from the moment the sluice is opened until the last drop of water leaves the pipe at the debouching end? The wind blows up from the debouching end, but forget this in answering these questions. My impressions are:—1. That air would be pushed before the flushing-water, and escape from untrapped openings and weak traps before the air be disturbed at the opening or debouching end of the pipe. 2. That air would escape at the top end of the pipe for a few minutes directly after opening the sluice. 3. That a very little air, if any, would be pulled in the pipe during the steady run of the water half filling the pipe, but that air would be pulled in when the water subsided. 4. That in sewer-pipes under these conditions air should not be bottled up by trapping street-gullies, and not providing for ventilation.—SANITATION.

[6743].—Liability of Yearly Tenant.—For what dilapidations is a farmer liable, who has held a farm within fifteen miles of London for fifteen years as a yearly tenant without there being any sort of agreement whatever? Is he liable for inside and outside painting of house, whitening ceilings, papering walls, renewing sash lines and broken glass, repairing tile and wood floors, repairing roofs of house and buildings, renewing decayed wooden eaves, spouting, and fencing, making good defective weather boarding and tarring same, repairing and pointing up brickwork, &c.? I am told the custom of the district, or estate, is for the tenant to pay for labour, landlord providing materials. With the exception of providing a few new gates, nothing has been done during the tenancy, but in the absence of an agreement can this be enforced? Again, I am told that if the tenant be at all liable, it is only for dilapidations during the last year, but how is the amount of this to be ascertained with buildings in such a wretched state? Should not the landlord or his agent have applied to the tenant to carry out the repairs from time to time, or have done the repairs himself? I have Fletcher's "Dilapidations," which is a valuable book, but is somewhat vague on this point, and therefore I should be obliged if any of your numerous contributors could give me some clear information on the subject.—SERIA.

[6744].—Measuring Hay-Ricks.—Would some practical reader kindly give me a few hints on measuring hay-ricks, or the name of a good book on it, and oblige—KANYARA.

[6745.]—**Fines**—In the event of a contractor failing to complete his contract within the specified time (without extension of time being granted by the architect) can the fine usually mentioned in the agreement for such incompleteness be legally enforced?—**NODLEY**.

REPLIES.

[6679.]—**The White House** is so-called because it happens to be painted white. It was built, says Johnson's Encyclopædia, between 1818 and 1829, of freestone. It is 170ft. long and 85ft. wide, and two stories high.—**R. M. TUTTLE**, Providence, R. I., U.S.A.

[6681.]—**Beer-Stone**.—The question is asked whether Beer-stone is a good workable material; and whether it has been largely used in church building as interested folk assert it has been. There is no doubt of Beer being easily worked. Reviewing South of England soft stones, it is more cheaply masoned or carved than Ankerst, Tisbury, Ketton, Ham Hill, Painswick, or Doulton. It is readily worked than Caen, and almost as cheap in the labour that has to be put on to it as Bath. Beer-stone is as much like Church (without the abominable "pins" which occur in the latter) as any material I know; but is, I think, a better stone. I certainly know no more economical stone in the market for pits, font, arcades, &c., &c. I had a fine block of it delivered at my yard only yesterday, sound as a bell, and weighing over seven tons; it will be cut up into a reedus for a Cornish church. I do not know how largely the company assert that it was used in former ages; but of the one thousand and odd fifteenth-century churches existing in Devonshire, Beer-stone was, without a doubt, the material used for dressings in three-fifths of them. At Exeter's cathedral a great deal of the most delicate interior work is of Beer. The porch screens, the marvellously beautiful sedilia, whose light masonry stands to-day as if its stonework since William de Montacute carved it in 1143; a window, and without a rival in the country for grace and elegance; Bishop Oldham's ornate little chapel, in the south-east of the choir, simply one mass of Late perpendicular detail; the last-mentioned rich Speke Chapel, the exquisite Late Early English arching in the Lady and neighbouring chapel, &c., &c., are chiefly wrought out of Beer-stone. In the Devonshire churches generally, the roof-screens are almost invariably of oak; one exception to this rule is the singularly fine one at St. Mary's, Totness. This grand perpendicular screen, and the adjacent pardoys, are of Beer-stone; whilst the windows and dressings of very many West country churches are of Beer-stone. I am not prepared to say whether it stands atmospheric influences better than Bath. The oldest genuine Beer-stone outdoor masonry that I know is the quaint Guildhall front, in Exeter's High-street. This was built in 1591, and since then, I believe I am right in saying, has not been touched. The detail is in a somewhat decayed state, but it speaks well for the stone that it has stood in place, and has done serviceable duty for 287 years. Readers will remember my friend, Mr. James Crocker, F.R.I.B.A.'s carefully-measured drawing of this front which was published in this journal in 1874 or '5. A large fire occurred a fortnight ago immediately in front of the Guildhall all in question, by which four houses were consumed. One of these was formerly an old inn called the "Eagle." I have seen a reference made to it dated 1437. In 1472, during the mayoralty of Hugh Gernyn, it was ordered that "the Eagle over against the Guildhall shall be employed and put to the use of a Cloth Hall, and that all foreign clothiers resort to the cloth with their cloths shall sell the same in that house, and not elsewhere within the city." Afterwards the building became a famous book-shop, known during the latter part of last century, far and wide, as "Dyer's Library." The street is very narrow thereabouts, but the devoting flames which unfortunately consumed this historical old house with its three neighbours, happily did no harm to the Beer-stone facade of the venerable Guildhall opposite. Why Beer-stone fell into disuse during the past two hundred years I have no idea, without it may be attributed simply to the fact that the land on which the quarries are situated belonged to folks with ample means, who had no particular stimulus there for pushing it in the building market. Further, it is only within the last few years that the quarries have been in communication with the railway; from this they are now some 2½ miles distant. I believe the stone lies, in the open quarries, in some eight or nine beds. The uppermost one of all is burnt for lime. Amongst my masons the fifth and seventh "spotty" beds are the favourite ones.—**HARRY HEMS**.

[6685.]—**Variation of Compass**.—If "L. L. U." will refer to the *PHILADELPHIA VIEWS*, Vol. XXXIX, p. 662, for 3rd December, 1881, he will find a method of obtaining the variation in the most accurate manner if he is able to obtain the correct Greenwich time, which has the most decided advantage of being worked in daylight, and therefore decreases to a minimum the chances of error. The best article I know of is in the "Land. Brit."—**W. G.**

[6707.]—**Softening Putty**.—I find in an old note-book the following:—"A red-hot iron will soften or remove the hardest putty." I have never tried it myself.—**C. F. M.**

[6708.]—**Plumbers' Solder and Smudge**.—The information desired can be obtained from a letter in the *BUILDING NEWS* of June 18, and one of a series of papers on June 24 in the same journal, both being by Mr. P. A. Davis and published this year. The book mentioned last week in *Woods's Series* should have been "Buchan's" not "Buchan's."—**H. M. LACHLAN**.

[6709.]—**Run full Sewage, &c.**—Besides the work given in "G. H. G." last week "F." might study the two works by Mr. G. Drysdale Dempsey, C.E., published in *Woods's Series*:—"The Drainage of Towns and Buildings" and "The Drainage of Districts and Lands"; these can be had separately or in one volume, the price of the latter being 3s. 6d. Also "Drainage and Storage of Water" by Mr. J. Bailey Denton, C.E., a criticism wherein will be found in the *BUILDING NEWS* for Sept. 4, 1874, and "Remarks on How to Estimate it" in the same journal, Aug. 16, 1878. Mr. Dempsey gives us an extreme a fall of two inches in twenty minutes on a hot July day.—**H. M. LACHLAN**.

[6713.]—**Shoring**.—I am much obliged to "G. H. G." for his answer. It occurred to me that there might be

some Institute Paper at least on the subject, or else on Damp-rooms Structures. I mention the latter because the case I have in view might be considered analogous. It is that of an external wall, about 35ft. high, supporting a mansard roof. It is proposed to remove all the middle portion of the wall, leaving the upper 10ft. and the lower 5ft. remaining. On the lower portion iron columns will be erected, 10ft. apart, supporting a girder, which will carry the upper portion, and consequently the roof. Knowing, from various instances of falls of old houses and walls, that old brickwork is treacherous enough to deceive experienced men, I am more anxious to know what dangers to be on the watch for, than to take up this valuable column with the discussion of principles already taught in textbooks on mechanics. I cannot think that carelessness can have been the sole cause of those falls of old walls which have happened under the very eyes of competent architects; and if I can be referred to some book, or treatise, I shall esteem it a favour. I am unable to attend Mr. Roger Smith's lectures.—**W. G. M.**

[6718.]—**Back Pointing in Tiling**.—I should say the inside pointing; this is, however, only an opinion.—**HUGH MACLACHLAN**.

[6719.]—**Specifying Painters' Work**.—It would be difficult for anyone to say which is the best kind of paint to use, there being so many various kinds in the market, most of which I believe are very good. I would not remove old paint on stucco unless very badly blistered, if a few blisters are found, break and stop them. If new work three or four coats; if old, two will be sufficient. Do not paint repaired stucco for at least six months, and if it has been done in autumn leave the painting for another year. See answer to 6715.—**HUGH MACLACHLAN**.

[6721.]—**Seats for Lecture Hall**.—It depends on the size and plan of the hall. If small, there is no better plan than to have the seats parallel and facing the platform. If it is wide, with, say, four rows of seats, arrange the central ones as last, but turn the side ones at an angle towards where the speaker would stand. If any seats are at the sides of speaker, turn them inwards at right angles to the central rows. In very large halls the seats have been placed in concentric rows, the position of speaker or some point behind being used as the centre. Avoid where possible a part of the auditory looking another in the face unless at least 2½ ft. apart, also have no concentric rows of small radii, as this serves to jam, so to speak, the knees of those using them.—**H. M. LACHLAN**.

[6725.]—**Draughts**.—These are caused in the case mentioned by the difference of the internal and external temperatures. The warmer air of the room strikes against the glass, which being of a much lower temperature owing to the cold outside, chills the warmer air and causes it to fall on any person in the room situated below the window or skylight. To remedy, use double windows as in Russia and Germany in the winter, or at least double glazing with an air space between about 1½ in. wide. With skylights it is better to have two where possible, an inner and an outer. By this means a body of air of medium temperature is interposed between the interior and the exterior.—**H. M. LACHLAN**.

[6726.]—**Girder**.—Would "H. D." please to state whether his girder is supposed to be loaded on the upper or lower boom (top or bottom). I believe it is structurally incorrect, but if he gives me the information asked for I will try to answer the question and show improvements in girder. He may work it out himself if he will study any of the works given in my answer to No. 6674, or perhaps better still, one of those mentioned by "G. H. G." in answer to some question on the same or a similar subject in the present volume of the *BUILDING NEWS* (since June); my copy is not at hand or I would mention the number. I do not believe there are near one hundredth of the books on the subject given by P. Playfair. The "Graphic method" properly so called appears to have been introduced in 1857 by Professor Maxwell.—**HUGH MACLACHLAN**.

[6727.]—**Window Lights**.—No, nor ever likely to be so, the present law being considered by authorities already too stringent.—**H. M. LACHLAN**.

[6728.]—**Drainage of Towns**.—Read the books referred to by "G. H. G." and myself in answer to No. 6709, in last week and this.—**H. M. LACHLAN**.

[6730.]—**Asbestos**.—Atmospheric burners must be used. Asbestos fire with eleven jets, heating a room about 14ft. by 12ft., consumes 3½ ft. of gas per hour when full on. Oven, 1600, by 18 in. by 24 in., with twenty-four jets, consumes 24½ ft. per hour, and circular burners, 3 in. diam., for kettles, &c., 10ft. per hour. Asbestos fires are doubtless more expensive than coal, but for convenience, cleanliness, and saving of labour, there is no comparison between the two. For cooking, I think gas will be found the cheaper, and it requires much less skill in management. Great care, however, is required in making proper provision for carrying off the fumes, as the heat generated is insufficient to make a good draught in the flue. With asbestos fires it will be found that when turned partly off they make a roaring noise. To obviate this, I have had a separate service laid to these fires from the meter, and a stop-tap fixed near the meter, so that they can be regulated from that point. A separate service is also a convenience, because it insures a regular supply for lighting. For sitting rooms in general use, coal fires are doubtless preferable, but for offices, bedrooms, and rooms in occasional use, asbestos fires are invaluable.—**J. D. TAYLOR**.

[6731.]—**Old Crosses in West of Cornwall**.—Scarcely all the ancient crosses, with which this remote part of England abounds, are of grey granite. In some instances the material seems to have been brought a considerable distance, as for instance in the case of that at Pridmore, which stands at least ten miles from anywhere where granite is procured. It is a tall cross over 5ft. high, and is of the common shape assumed by Cornish crosses, i.e. a tall upright shaft surmounted by a circular head. Upon the face of the cross. In some instances there are also sculptured figures. Amongst the crosses of this local shape, I may mention those existing at Anjarden, Brance, and Tremegon Hill near Sancerre, and three at Sancerre itself. Also at Trevaun, St. Paul, Velensayer, Boskenna, Nun Carrog, Cronz-an-wra, and Trevoargance, all little places near St. Buryan, and one, too, at St.

Buryan, as well as at Trevillyn, and at Maen, near Sennen, and also at Sennen itself. At Penden, near St. Just, and at St. Just, at St. Erth (2), at Hea, Tremebath, Trengwainton Cairn, and Pore-an-Grow, all in the neighbourhood of Madron. There are others, and two exist at Madron; on St. Michael's Mount, at Phillack, Illogan, Gwinnar (2), Zennor, Trengwainton, Bosworth, and Penzance. There are more, again, at Brumman Cairn, Treowen Hill, and Rosejarn, near Lelant, and upon the roadside between Lelant and St. Ives are others. At Lelant itself there are three more. At Camborne there are two. Between Carnal-green and Clowance, and at Clowance also old crosses are to be seen. At Connor Down, near Gwinnar, is another, and at Cury, Rosemorton, near Gulval, Whitecross, near Ludgvan, Trewheld, near St. Hilary, and at Gwythian there are old crosses also. At Helston there are two, and the same number at St. Levan. At Chygydden and at Rosepheth, both near St. Levan, are others, and there is one at Penbeagle, near St. Ives. All of these assume the same definite outline. Some are more fragmentary circular heads, others are perfect. The finest, perhaps, as regards height, is at Cury Churchyard. It is 9ft. high. The most elaborate is in the graveyard at Sancerre. It is between seven and eight feet high, has a figure carved upon its uppermost part, and is otherwise highly ornamental. Besides these crosses of purely local shape, there are many still to be met with which assume the Latin form. Amongst them may be mentioned remains at Trefere—St. Paul Down, Ludgvan, Bosworth, and Tremethick, near Madron, at Chyowne, and at Trengwainton Down, both near St. Buryan, and at Hucher Drift by Sancerre. Also at Escalls, near Sennen, Mether Uny, near Helston, Landewednack, St. Keverne, and there is one upon the Breaze road. Whilst these crosses are all more or less characteristic ones, there are others in Western Cornwall whose forms are unique in the locality. The fine cross (10ft. 6 in. high) in St. Ives churchyard, and a similar one at Lanteglos (10ft. 6 in. high), are unlike anything else that I know in the county, and so is the pinnacled and canopied sculptured head of a highly ornamental cross preserved at St. Michael's Mount. Again, in the churchyard of Gulval, and in St. Mary's churchyard at Penzance, there are crosses of curious form. In a garden at Helston is one of rare design. It was found many years ago at Trevaun, in the parish of St. Kew. I believe that the above embraces all the not resting old granite crosses down "west along," but possibly there may be a few others which have slipped my memory.—**HARRY HEMS**.

[6732.]—**Down-Draught in Chimneys**.—Having had one that baffled the skill of four chimney doctors, and was pronounced an incurable (for when the wind was in the S.W. down came the smoke), I then called on Mr. Shorland, the inventor of the patent Manchester grate and several other useful systems of warming and ventilating, who at once cured it. The most remarkable thing in connection with this cure is that it never smokes into the room now, and when the wind is where it used to be when it filled the house with smoke (for it literally blew the fire out of the grate into the room), now it burns the brightest, still there is no great consumption of fuel. My chimney is in an outside wall against the S.W., in a very exposed situation, no houses being near for many miles.—**JOSSEPH MEE**, Brookside, Whalley Range, Manchester.

[6737.]—**Pull on Casting**.—The following will probably aid in answering "Severne's" question. First, taking the weight of casting into account, let the pull at B be called P; the load at C, W; the horizontal distance BC, x; and the vertical distance AB, y. The part of the casting AB, being vertically over A, does not tend to turn either way, and may be neglected, but the part BC the weight of which is called w, tends to turn in the same direction as the load, thus assisting it, and should be taken into account. See diagram in last week's issue. Now, taking the moments of the several forces about A as a centre, we obtain—

$$\text{Moment of the load} \dots \dots \dots W \times x, (1)$$

$$\dots \dots \text{part of casting BC, very nearly} \dots w \times \frac{x}{2}, (2)$$

$$\dots \dots \text{pull} \dots \dots \dots P \times y, (3)$$

To cause equilibrium, (3) must be equal to (1) and (2) taken together.

$$\text{therefore } P y = W x + w \frac{x}{2} = \frac{x}{2} (2W + w)$$

$$\text{and } P = \frac{\frac{x}{2} (2W + w)}{y} = \frac{2y}{x} (W + \frac{w}{2})$$

But in this case $x = y$, therefore $P = W + \frac{w}{2}$. If the weight of the part of casting be neglected, $P = W$, or the pull at B is equal to the load at C, and as the load is 2½ lb., the pull will also be 2½ lb. The problem may be worked graphically thus—Resolve W into two forces, one acting through A, the other horizontally through B. Treat in the same manner. Add the two horizontal forces acting through B, which will be equal to P.—**ANTHONY R. F. TLEW**.

A Swedenborgian Church is about to be erected in the Station-road, Snodland, Mid-Kent, from the plans of Mr. Henry Bridg, of Maidstone. It will be built of Kentish ragstone, with Bath stone dressings, and will be Gothic in style, consisting of nave 50ft. by 30ft., chancel 20ft. long, organ chamber, vestry, and tower.

The town-hall and market-house at Maesteg were publicly opened on Saturday. The building is Queen Anne in style, and is built of stone with terra-cotta dressings. It consists of a covered market on ground floor, a public hall seating 1,300, and an assembly or board-room above, and offices for the clerk, solicitor, and surveyor; in the tower has been placed a town clock. Mr. H. C. Harris, of Cardiff, was the architect, and Mr. George Thomas, of Newport, Pembrokeshire, the contractor.

LEGAL INTELLIGENCE.

BUILDING MATERIAL.—At the Edmonton Petty Sessions, on Monday, before Mr. J. Abbiss and other magistrates, Henry Capsey, of May-house, Stamford-hill, builder, was summoned, at the instance of the Tottenham Local Board, for being engaged in building on the north side of St. Ann's-road, Stamford-hill, a house which was not solidly put together. Mr. E. Crowne appeared in support of the summons. Mr. De Pape, surveyor to the Local Board, produced three samples of mortar which he had taken from near the mortar mill, the mortar heap, and from the walls of the house respectively, and which crumbled to pieces when touched with the fingers. Defendant admitted the use of the two last-named samples, which he said were what he had made use of for years in the metropolitan district, but the first-named sample had been shot there by mistake. There was a second summons against the defendant for a similar offence. He was fined £5 in each case, and £2 10s. costs, the alternative being 21 days' imprisonment. The penalties were paid.

WATER SUPPLY AND SANITARY MATTERS.

WAKEFIELD WATER SUPPLY.—The first sod of the proposed Ringstone reservoir, on the Rishworth Moors, for the supply of Wakefield, was cut on the 18th inst. The site of the reservoir is a tract of high-lying wild moorland, on the Savile estate, 20 miles west of Wakefield. The average annual rainfall is 45in., and the subsoil is gritstone and shale of the Millstone-grit formation. About 3,200 acres of gathering-ground will be available, and after providing two millions of gallons per day as compensation to millowners, about four millions of gallons per day will be yielded for Wakefield in the driest seasons. The principal works are:—1st. A compensation reservoir called Green Withens reservoir, to contain 240 millions of water, situate at the uppermost end of the gathering-ground, for the supply of millowners. 2nd. A storage reservoir, called Ringstone reservoir, to contain 200 millions of gallons, situated at the lowest end of the gathering-ground, to be used principally for the supply of water to Wakefield. 3rd. A storage reservoir, called Ardsley Reservoir, to contain 300 millions of gallons, situated about three miles north-west of Wakefield; this reservoir is entirely devoted to the supply of Wakefield, and will contain about five months' supply at the present rate of consumption. 4th. A service-reservoir on Lindle-hill, about two miles from the town-hall at Wakefield, intended to contain a few days' supply. 5th. A catchwater-conduit, called the Moss Moor Catchwater, from the uppermost part of the gathering-ground down to Ringstone Reservoir. 6th. A line of iron pipes to be laid from Ringstone Reservoir to Ardsley Reservoir, and thence into Wakefield. These will be 21in. diameter for the first three miles, and 18in. the remainder of the way. There are other intended catchwaters and filter-beds, the latter between Ardsley and Lindle-hill, but these works will not be proceeded with at present. The contract for pipes has been let to Messrs. Cochrane, Grove, and Co., Middlesbrough, at about £47,000; that for stop-cocks and fittings to Messrs. Guest and Chimes, of Rotherham, at about £700; and the pipe-laying to Mr. Samuel Jowett, of Brighouse, at £10,000. About three miles of pipes have been delivered, and laid in the ground. The contract for the Ringstone Reservoir has been let to Messrs. Metcalfe and Sons, of Bradford, at £31,710. The site is not in the valley itself, but in a saucer-shaped hollow, 400ft. above it, placed between three hills. Two embankments will be needed to retain the water. The western or main one will be about 1,600ft. long, and 60ft. at deepest part. The base will extend to 400ft. in breadth, and the embankment will taper upwards to 20ft. at the top. It will contain about 200,000 cubic yards of earth, and will have a water-tight puddle wall placed in its centre from top to bottom throughout its length. It will be pitched with stone on its water slope, and soiled and grass sown on its outer slope. The lesser embankment will be 1,200ft. long, and about 24ft. high at the deepest part. The base will be 120ft. broad, tapering to 40ft. at top, on which a roadway will be carried. The weir and bywash will be placed at southern end of main embankment; the former will be 30ft. long and of solid masonry, the bywash 15ft wide and 550ft. in length, pitched with stone throughout. The valves will be constructed in valve-shafts 10ft. in diameter, built in brickwork and covered by domed entrances built in masonry. The engineer for the whole of the works is Mr. E. Filtiter, M.I.C.E., of Leeds, his resident deputy being Mr. Ellis, of London. Mr. McGawley is clerk of works.

EASY-GOING SEWERAGE SUPERVISION.—Some curious irregularities in connection with the inspection of a sewerage contract, of which Mr. Alfred Williams, C.E., was the engineer, were

brought to light the other day at a meeting in committee of the local board for Bromley, Kent. The object of the meeting was "to select test cases for investigation in the district sewered under Mr. Garton," who is in the service of the board as inspector at a salary of three guineas per week. The Chairman explained to Mr. Garton that the board were desirous of testing the work executed under his supervision, to ascertain whether the extras certified for, especially the large items of concrete, were actually supplied. In the course of an examination, Mr. Garton admitted that he could not indicate on the plan of the Burnt-Ash-lane sewer, where had been laid the twelve lengths of concrete, paid for under certificate No. 8. After some further fencing with the question, he said the truth was when No. 8 certificate was paid this concrete was not executed, and he consented to pass the item in order to oblige Mr. Potter, the contractor, who was very short of money at the time. It was done at the solicitation of Mr. J. G. Stead, then the contractor's clerk of works. The charge was not, he protested, a fraud, as the concrete was eventually laid down. This certificate was passed in August, 1880, and a week or two after Mr. Garton said he went to Winchester to be married. Pressed as to whether Mr. Potter sent him any money when there, he denied it, but ultimately admitted that Mr. Potter sent a wedding present of £5 to his wife. He was then shown a letter written on the Bromley local board official paper, which he admitted was in his handwriting; it was addressed to George Potter, and ran thus:—"Sept. 22, 1880. Dear George,—I am just off. Please send the other money as soon as you can, as I could not speak to you this morning. Send P.O. order to me at No. 17, St. James'-villas, Winchester, made payable to me at the Post-office, Winchester—please send it as soon as you can—send it from London please—be sure to send. Yours truly, John Garton." In reply to other questions, he said the "other money" referred to business transactions with the contractor, which had nothing to do with the certificates. He could not explain the letter. A member remarked that they were free to put their own interpretation on the affair. In reference to the concrete in the Ravensbourne-road sewer, Garton said no concrete was laid, and although a charge had been made for it, he had struck it out in May. On the suggestion of Mr. Stead, the June bills were examined, and the items were found to be certified and paid for. Some discussion arose as to the extra depth of manholes, and Garton said the 630ft. of concrete charged for in certificate No. 8 was at the bottom of 23 manholes, which were used as pumping stations. The members then visited Burnt Ash-lane, the district certified for, and found no concrete round the pipes, although it was charged for in the certified bill as having been laid 2ft. 6in. wide and 9in. deep. At an adjourned inquiry, held last week, Mr. Thurston, the inspector of nuisances, was examined as to the work done while he acted as assistant-inspector of sewerage, and other irregularities as to the amount of concrete used were elicited, he being unable to tax his memory with the amount of the material used. In the Burnt Ash-lane sewer he saw but two pieces of concrete laid. On Friday last, says the *Bromley Telegraph*, to which journal we are indebted for our report, four openings were sunk at as many manholes, in Burnt Ash-lane, under the supervision of the board's surveyor, and the allegation made by Garton, that these places had all been used as pumping stations, was negatived by the nature of the soil, which—except in one place—proved to be a bed of fine dry sand.

LONDON WATER SUPPLY.—About a dozen delegates from vestries and district boards in London met on Wednesday in the Vestry-hall of St. Martin's, under the presidency of Mr. E. J. Watherston, to consider the question of the water supply of the metropolis. There were representatives from Islington, Kensington, Limehouse, Wandsworth, Mile-end, Clerkenwell, Fulham, and a few other places. Mr. Watherston explained that the meeting had been called to urge the Government to take steps to deal with the water question next session, to which end it was necessary that Parliamentary notices should be given next month. The consequences of the inability of the Government to legislate on this subject last year were most serious, owing to the reassessment of the metropolis, of which the water companies had not been slow to avail themselves. Further delay was very much to be deprecated. The Grand Junction Company and Southwark and Vauxhall Company failed last summer in their high service supply. Moreover, if the question were shelved any longer, either by the apathy of Parliament or by the action of those who desired the previous unification of London government, it was difficult to see how Parliament could avoid granting extended capital and fresh powers to the water companies, all of which would add considerably to their claims for compensation when the inevitable

day of purchase arrived. As it was, the revenues of the companies had increased, and were increasing at a rate even beyond all previous calculation—a circumstance attributable not only to the normal increase of houses, estimated at about 25,000 annually, but also to the fact that the companies, released from the arrangements for purchase, had, in many instances, although admittedly within their Parliamentary limits, raised their charges upon the basis of the re-assessment of metropolitan property. Some discussion took place as to the action which the conference ought to take, but ultimately it was agreed to transmit a memorial to the Prime Minister representing the increasing charges which the ratepayers of the metropolis had to pay to the water companies without obtaining any equivalent in the shape of a purer or more copious supply, and urging the Government to legislate on the subject next Session on the lines of the report of the Select Committee of last year. A small committee was appointed to receive and consider the reply which Mr. Gladstone might make, and to report to the conference on an early day.

CHIPS.

Three hundred yards of the new sea-wall at Eastbourne have been swept away by the sea; the estimated damage exceeds £10,000. The contractor, Mr. Jackson, attributes the damage to the refusal of the town council to erect certain groynes.

Primitive Methodist Sunday-school buildings, accommodating 300 children, were opened in Tipton-street, Sedgley, on Sunday. Mr. Hulton, of that town, was the builder.

St. Mary's parish church, Cold Brayfield, was reopened by the Bishop of Oxford on Monday week after restoration.

The partnership between Messrs. Branch and Rayner, architects, of London and Brighton, has been dissolved.

The memorial-stone of a new Congregational church was laid at Burgess-hill, Sussex, on Wednesday week. It will be Tuscan in style, built of brick coated with Portland cement; the dimensions are 60ft. by 40ft., and accommodation will be provided for 400 persons. Mr. E. J. J. Hamilton, of Brighton, is the architect, and the contract for erection has been taken at £1,995 by Mr. Simeon Norman, of Burgess-hill.

Last week judgment was given in the sheriff's court, Greenock, in an action brought by a labourer named John Creighton against the Greenock Foundry Company for £127 as damages for injuries received by him in defendants' service in March last. The sheriff said he was obliged to dismiss the case, as notice in writing was not given to the defendants by plaintiff within six weeks of sustaining injury, as required by the Employers' Liability Act, 1880.

During the late congress of the Kent Archaeological Society, a visit was paid to the site of a Roman villa discovered at Wingham, about four miles from Sandwich, by Mr. George Dawker, who had, at that time, laid open one apartment only. Since then he has excavated several more rooms, and ascertained that the villa appears to have been very spacious. Two of these rooms have ornamented tessellated pavements; and a third, which appears to have been a bath, is decorated also upon the walls with tessellated work in black and white, to which it would be difficult, in this country, to point to another example.

The Sussex magistrates at the Michaelmas Quarter Sessions last week accepted the recommendation of the highways committee, and appointed Mr. Thomas Skinner, of Horsham, as county roads surveyor, at a salary of £100 a year. The duties are to personally inspect all main roads, including those over bridges, to give directions to parish surveyors, and to grant certificates under the Highways and Locomotives Act, 1878. Extra remuneration will be given should the surveyor be called upon to report on and superintend repairs to ordinary highways.

The foundationstone of a new Primitive Methodist school-chapel was laid at Kluishill, New Swindon, on Monday week. The building will be 34ft. by 27ft., will seat nearly 200 people, and will cost about £300. The contract for erection has been taken by Mr. T. Colbourne, of Stretton Cross-roads.

The old grammar school, at Steyning, Sussex, is about to be enlarged and renovated, from the designs of Mr. Gordon M. Hills, of Adam-street, Adelphi, London.

The first meeting for the third session of St. Paul's Ecclesiological Society was held on Tuesday evening at St. Paul's Chapter-house, when Mr. Alfred Tylor read a paper upon "The Roman Antiquities recently discovered in Warwick-square, E.C."

Our Office Table.

GRATIFYING evidence is given of the benefits, in a sanitary sense, afforded in London by the model dwellings known as the Peabody Buildings. It seems that the deaths in these buildings, calculated upon sixteen years' experience, have been at the rate of only 16.7-10 per thousand per annum, while the general death-rate for the metropolis during the same period has been 23.4-10. According to Mr. Vigers' evidence before the Select Committee on Artisans' Dwellings, the death-rate in crowded districts surrounding the buildings may be taken at 30 or 40 to the thousand. This is encouraging news in prospect of the working of the alterations now being carried out in Birmingham under the provisions of the new Improvement Act.

THE removal of the machinery from the Abbott's Cliff leading to the shaft at Shakespeare's Cliff, in connection with the Channel tunnel experiments, is now complete, having occupied upwards of two months, and boring operations will be commenced almost immediately. The scheme is now in the hands of the South-Eastern Railway Company, who, we understand, have entered into a contract for the drilling to be extended another mile. For the present the boring will be continued in the direction of Dover. Several workshops and sheds have been erected at the mouth of the shaft, and a powerful engine has been fitted up. The arrangements are now much more complete than formerly, and are calculated greatly to facilitate the progress of the work. The cuttings from the face of the chalk are carried to the rear of the engine by caps, and afterwards conveyed in an iron skiff from the engine to the mouth of the shaft by means of pulleys attached to a drum, which is worked by machinery. With the present arrangement, the same amount of work will be able to be performed with a considerable reduction of labour, about 30 men only being required instead of double that number, as at the Abbott's Cliff heading.

THE custom of employing artists to paint the outside of houses with artistic designs, which formerly prevailed in the South of Europe and Germany, has lately been revived in Munich. The *Kunst Kronik* gives an account of two houses which are attracting some attention from the beauty of their exterior decoration. One is an hotel, and has been painted in the style of the Later Renaissance; the other is the house of an artist, and is said to offer a rare combination of fitness and aesthetic worth. The process employed in this kind of painting is not fresco nor the water-glass method used by Macleise in his wall-paintings at Westminster, but some kind of mineral painting (*Mineralmalerei*), of which further particulars are promised. If it will withstand the influences of climate, it will be of service.

THOSE in favour of the appointment of a Minister of Fine Arts may feel some interest in the recent action of the French people, who certainly display an intelligent interest in the cause of Art, and have on one or two occasions tried the expedient suggested. Their verdict seems to be that under the Empire the result was corruption, and under the Republic feebleness and uselessness. By a decree just promulgated, the semi-independent posts of Director-General of the National Museums and Permanent Secretary of the Fine Arts Department, are, together with the titular Minister, suppressed. The administration of science and art, as we should call it in this country, is made a subordinate branch of the Education Department, under the special direction of the Under Secretary of State for that service, and the executive officers acting directly under him are to be the Director-General of the National Museums and the Director of Art Works, on whom will devolve the selection of all paintings, sculptures, and other products for the national collections.

THE report of Colonel Henderson for the year 1880, just submitted by him to the Home Secretary, shows that house building in the Metropolis is proceeding steadily. From the year 1873 the proportions of this business have been increasing, each year adding vastly to the total number of structures and the aggregate

superficial area occupied by them. In 1875 there was 10,023 houses added to London, and, roughly speaking, these figures rose by nearly 3,000 in 1876, another 2,000 in 1877, and 1,300 in 1878. In 1879, 21,589 houses were built, forming 401 streets and two squares, and making a length of over 71 miles. Last year there were built in London 21,945 new houses, forming, 145 streets and two squares, and measuring over 69 miles.

THE first statutory meeting of the Sanitary Protection Association for London was held on Tuesday at the Society of Arts' room, Adelphi, the president, Professor Huxley, in the chair. Mr. Timothy Holmes, M.A., the treasurer, stated that the association had been in operation only for a few months, and for a certain portion of that time its action had been suspended by legal difficulties. The number of members enrolled up to the 15th of this month was 126, the total contributions, together with a loan of £100 from Professor Jenkin, was £391 11s., and the total expenditure £316 3s. 6d. Professor Fleeming Jenkin, F.R.S., explained the origin, objects, and working of the association, which, he said, gave sanitary advice to its members on very cheap terms. Professor Huxley said that, to put it briefly, the association was a new co-operative store for the supply of good advice, and the modest success which had hitherto attended it was very likely due to the antipathy inherent in human nature to the reception of good advice. Their good advice, however, had this peculiarity—that they did not expect anybody to take it unless he liked. His interest in this association came from the remote connection he once had with medicine and hygiene. He had been led to the conviction, strengthened by every day's experience of life, that when we aggregated close upon four millions of people on something less than 50 square miles, if we did not take care we should be desolated, not like old London by the Plague or Black Death, but by those other forms of disease as fatal in their way which have the terrible peculiarity of being easily disseminated by the very means we took to get rid of them, unless those means were perfect. Disagreeable as the old cesspool system was, it was attended with very little danger compared with that which waited upon the water sewage system if that system was imperfect, for then it was an admirably contrived arrangement for distributing disease and death in our own houses and in the houses of people who lived adjacent. There were two ways of meeting the danger. One was by the action of Government in some shape or other, which would not be tolerated in England, besides, the expense and difficulty of working such a system rendered it impracticable. The other way was to do the inspection of her oneself or by persons whom one could trust, who, like the officials of that association, had no interest in making a report. Therefore, it was for the public good that the association should become a great one, and its work be carried out as widely as possible.

THE first meeting of the one hundred and twenty-eighth session of the Society of Arts will be held on Wednesday, the 16th November, when the opening address will be delivered by Sir Frederick J. Bramwell, F.R.S., Chairman of the Council. The following are among the papers which will be read during the session:—"The American System of Heating Towns by Steam," by Captain Douglas Galton, C.B., F.R.S.; "Stained Glass Windows," by Lewis Foreman Day; "The Production and Use of Gas for Purposes of Heating and Motive Power," by J. Emerson Dowson; "Gas for Lighthouses," by John Wigham illustrated by an exhibition of some of the gas flames and apparatus used in lighthouses; "The Relation of Botanical Science to Ornamental Art," by F. Edward Hulme, F.L.S., F.S.A.; "Tools and Cutting Edges," by D. A. Aird; "The Teaching of Forestry," by Colonel G. F. Pearson. The usual short course of Juvenile Lectures, given during the Christmas holidays, will be by Mr. W. H. Preece, F.R.S., the subject being "Recent Wonders of Electricity."

TYPHOID fever, with a fatal result, having been generated by the unsanitary condition and overcrowded state of the Exeter Post-office, the Sanitary Authority desired to inspect the establishment, in order that they might direct the necessary steps to be taken to improve the condition of the building. The Postmaster declined to permit the entry of the authorities, but

yielded when a magisterial order was presented. The state of affairs in the telegraph department was so bad that the Town Council pronounced the building to be dangerous to the health of the city. It was intimated that certain improvements were to be made, but the Postmaster declined to give particulars, claiming that Crown property was not subject to the Public Health Act. Application was then made to the Local Government Board. They communicated with the Postmaster General, who this week wrote giving the Council particulars of the proposed work, and promising that the new Post-office should be erected as speedily as possible.

LORD PENZANCE, sitting as Dean of Arches, had before him on Wednesday an appeal from the decision of the Chancellor of the Diocese of London, granting a faculty to the Rector of St. Mary-at-Hill, Thames-street, to carry out alterations in his church estimated to cost about five hundred pounds, to be taken from pious trust funds amounting to upwards of two thousand pounds annually. The appellants denied the necessity of the proposed expenditure, and stated that the average attendance at the church was only twenty persons. Lord Penzance reserved judgment.

THE Exhibition of Smoke-Preventing Appliances will probably open about the middle of November. This undertaking has been carried out by a joint committee of the National Health and Kyrle Societies, the object being to introduce to the notice of the public smoke-preventing appliances, in order to bring about the desirable result of smoke abatement. The exhibition will be held in the east and west arcades, and in the buildings adjoining the Royal Albert Hall at South Kensington. The chief departments will be domestic, industrial, and novelties. Trials will be made upon the exhibits, and gold, silver, and bronze medals and certificates of merit, are to be awarded upon the report of a special committee. At a general meeting of the joint committee held last week, Mr. W. R. E. Coles, hon. sec., who is working indefatigably to forward the general arrangements, announced that Dr. Siemens, a member of the committee, had offered a prize of 100 guineas to be given for the best method of arrangement "for utilising fuel as a heating agent for domestic and industrial purposes, combining the most economy with freedom from smoke and noxious vapours"; for the "Ladies' Prizes" (consisting of two sets of prizes of 50 guineas each) it was stated that there had been received from Messrs. Rathbone 10 guineas, the Baroness Burdett-Conings 10 guineas, Lady Pollock two guineas, to be awarded on trial by experts for the best open grates, and the best kitcheners combining (1) freedom from smoke, (2) simplicity in arrangement and use, (3) economy. The Society of Arts have also offered a medal to be presented by the special committee, and it is requested that Lord A. Churchill should represent them in reference to this award. Mr. D. Kinnear Clark has been appointed as attesting engineer to superintend the trials, and Mr. James Richards, of the Royal Albert Hall, has succeeded Mr. Gilbert Redgrave as superintendent of the exhibition, the latter having been compelled to resign in consequence of his appointment as secretary of the Royal Technological Commission.

CHIPS.

On Tuesday last Messrs. Driver and Co., of Whitehall, sold by auction at the Mart, Tokenhouse-yard, some small detached plots of land in Crown-road, Munster-road, and Margravine-road, Fulham, containing together 2 acres 3 rods and 10 perches, which realised a total sum of £1,810, or at the rate of about £1,720 an acre.

THE new lecture-theatre and other buildings lately added to the Birmingham and Midland Institute were opened last week. The new buildings have been erected by Messrs. Horsley Brothers, of Newton-street, at a cost of between £25,000 and £30,000, from the designs of Messrs. Martin and Chamberlain. They include a number of rooms affording largely increased accommodation for the Industrial Department and for the School of Art, and a lecture theatre capable of seating nearly 1,200 persons.

A new Baptist chapel in Grove-road, Eastbourne, was opened on Thursday week. It measures 63ft. by 39ft. inside, is faced with Johnson's red bricks with Bath dressings, and seats 500 people. Mr. Skinner, of Eastbourne, was the builder.

The memorial to the late Earl of Beaconsfield which is to be erected in Parliament-square, will be placed next to that of Lord Derby, and will look towards the Houses. It will be cast in bronze, will be 9ft. in height, and will stand on a granite pedestal 10ft. 6in. high. The design, as accepted by the committee, represents the Earl in a peer's robe, with a scroll in his left hand, and his right hand by his side. The work has been entrusted to Mr. Mario Raggi, and will cost between £4,000 and £5,000.

New schools are about to be built in Quarry-street, Stonehouse, for the East Stonehouse Local Board. Mr. H. J. Snell, of Plymouth, is the architect.

A new redos has just been placed in the parish-church of Hythe, Kent. It has been executed from the designs of Mr. G. E. Street, R.A., and contains a *bas relief* by Mr. H. Armistead, R.A.

The Wesleyan chapel at Wantage, Berks, was reopened on Tuesday week after renovation, including new seats throughout the chapel of varnished yellow deal, new organ gallery and rostrum of pitch-pine, and decoration in colour. Mr. Wannicot, of Farnham, was the architect, and Mr. John Wheeler, of Wantage, the contractor.

The district of Southwater, Durham, is about to be drained from plans by Mr. John G. Reah, surveyor to the local board.

A new chapel is in course of erection at Croft. It is Gothic in style, is faced with local granite, backed by brickwork, and will seat 250 persons. Mr. Gee, of Croft, is the builder.

New schools are about to be erected for the Aberdeen School Board in King-street, from the designs of their architects, Messrs. Ellis and Wilson, of that city.

ROYAL INSTITUTE OF BRITISH

ARCHITECTS.—THE FIRST ORDINARY MEETING OF THE SESSION, 1881-82, will be held on MONDAY EVENING, the 7th November, at 8 p.m., precisely, when the Ballot will take place for Seven Fellows and Thirty six Associates, and the opening address will be delivered by G. E. STREET, R.A., President.

NOTICE TO CANDIDATES FOR MEMBERSHIP.—No applications for the Associateship, under the old rules, will be received after the 31st December, 1881. The first Obligatory Examination will be held on the 15th, 20th, 30th, and 31st March, 1882, and the second in July. The regulations and programme of these examinations may be obtained gratis at the office of the Institute.

J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.
9, Conduit street, Hanover-square London, W.

MEETINGS FOR THE ENSUING WEEK.

THURSDAY.—Annual Dinner, Builders' Benevolent Institution, Freemasons' Tavern, 5 for 5.30 p.m.

Throat Irritation.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. Glycerine, in these agreeable confections, being in proximity to the gland at the moment they are excited by the act of sucking, becomes actively healing. Sold only in boxes, 7d. and 1s. 1d., labelled "JAMES EPPS and Co., Homoeopathic Chemists, London." A letter received:—"Gentlemen,—It may, perhaps, interest you to know that, after an extended trial, I have found your Glycerine Jujubes of considerable benefit (with or without medical treatment) in almost all forms of throat disease. They soften and clear the voice.—Yours faithfully, Gordon Holmes, L.R.C.P.E., Senior Physician to the Municipal Throat and Ear Infirmary."

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, BILIOUSNESS, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by Chemists throughout the world, and the M-Ler, 113, Holborn Hill. Use no substitute. See Medical Testimony.

Holloway's Ointment, aided by his Pills, presents the only rational mode of curing pimples, boils, carbuncles, abscesses, and other disordered diseases. Tainted blood, the fountain of these evils, is thoroughly purified by the Pills, and its evidences on the surface are effectually eradicated by the Ointment, without pain or danger.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset. —[Advr.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates. General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country. —[Advr.]

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.
PICTOR & SONS, BOX, WILTS.
(See trade advt. on p. XXV.) Advr.

Major (error)	832 17 6	835 17 6	

*Accepted, for iron principals.

LEIGHTON BUZZARD.—For shop front at Leighton Buzzard, for Mr. J. Haskins. Mr. F. Gotto, Leighton Buzzard, architect:—

Gibbs, Leighton Buzzard	£134 10 0
Webb, Leighton Buzzard	123 0 0
Forster, Leighton Buzzard	100 10 0
Dawson, Linslade, Bucks	98 10 0
Cook and Sons, Leighton Buzzard*	94 10 0

*Accepted.

LEIGHTON BUZZARD.—For converting two buildings into cottages, for Mr. R. Black. Mr. F. Gotto, Leighton Buzzard, architect:—

Whiting, Heath	£186 18 0
Gibbs, Leighton Buzzard	145 0 0
Webb, Leighton Buzzard	130 0 0

LIMEHOUSE, E.—For the enlargement of the Thomas-street School, Limehouse, by 480 places, for the London School Board. Mr. E. R. Robson, F.S.A., architect to the Board:—

Wood, F. and F. J.	£5,436 0 0
Pritchard, G. S.	5,239 0 0
Lawrence, E.	5,281 0 0
Nightingale, B. E.	5,181 0 0
Cox, C.	4,921 0 0
Harris and Wardrop	4,920 0 0
Jerrard, S. J.	4,850 0 0
Atherton & Latta, Poplar (accepted)	4,900 0 0

(a) Cost of school buildings only (including closets), £4,080; (b) cost of tar pavement and playground, £40; (c) cost of boundary-walls and gates, £180; (d) cost of teachers' room, £100; (e) cost of cookery class-room, £350; (f) cost of new infants' w.c. buildings, £50; total, £4,800. Cost per head of (a), £8 10s.; total cost per head, £10.]

LONDON, E.—For proposed new parsonage house at St. Peter's, London Docks, for the Rev. R. A. J. Suckling, Mr. Bowes A. Paice, architect. Quantities by Mr. C. Poland:—

For foundations and pulling down old building:—	
Dawson	£1,490 0 0
Lang and Son	1,407 0 0
Higgs and Hill	1,149 0 0
Colls	1,075 0 0
Dove Bros.	990 0 0
Brown	945 0 0
Cooper	878 0 0
Manley	790 0 0
Palmer and Son	725 0 0

For superstructure:—

Dawson	5,900 0 0
Colls	5,873 0 0
Lang and Son	5,229 0 0
Higgs and Hill	5,180 0 0
Dove Bros.	4,925 0 0
Brown	4,900 0 0
Palmer and Son	4,675 0 0
Cooper	4,644 0 0
Manley	4,447 0 0

LONDON, E.C.—For lighting the Saloon and Egyptian Hall, at the Mansion House, with electric lights and Swan incandescent lamps, for 12 months:—

Crompton, R. E. and Co. (accepted)	£425 0 0
------------------------------------	----------

LONDON, E.C.—For supplying and fixing complete low-pressure hot-water apparatus, for warming the Saloon at the Mansion House:—

Wontner, Smith, Son and Co. (accepted)	£326 0 0
--	----------

LONDON, N.—For erecting twelve houses in the Harringay-road, Green-lanes, N., for Mr. J. T. Pickburn. Mr. Smithers, architect:—

Harper	£4,906 0 0
Pawson	4,200 0 0
Henderson	4,200 0 0

LONDON, W.—For alterations and repairs to 14 and 15, Dorset-street. Mr. Haynes, architect:—

Vears and Co. (accepted)	£385 0 0
--------------------------	----------

LONDON, W.—For alterations and additions to Mr. Harrod's Stores, Brompton-road. Mr. A. Williams, architect:—

Larter and Son	£1,189 0 0
Martin, Wells and Co.	1,182 0 0
Langmead and Way	1,126 0 0
Benstead and Sons	994 0 0
Sprake and Foreman	980 0 0
Patman and Fotheringham	943 0 0
Stimpson and Co.	939 0 0

LONDON, W.C.—For completing certain works at No. 61, Russell-square. Mr. W. Paice, architect:—

Downs, W. B. and Co. (accepted).	
----------------------------------	--

LOUGHBOROUGH.—For widening and repairing the bridge over the brook leading from East Leake to Gotham, for the Highway Board. Mr. J. F. Hodson, surveyor:—

Faulks, Loughborough	£297 0 0
Haywood, Gotham	196 17 0
Sharnan, Kegworth (accepted)	158 0 0

LOWEA NOAWOOD.—For the enlargement of the Gipsy Hill-road School, Lower Norwood, by 400 places, for the London School Board. Mr. E. R. Robson, F.S.A., architect to the Board:—

Marsland, J.	£5,186 0 0
Jerrard, S. J.	5,116 0 0
Kirk and Randall	5,113 0 0
Hobson, J. D.	5,100 0 0
Stimpson and Co.	5,076 0 0
Lawrance, E.	5,069 0 0
Nightingale, B. E.	5,033 0 0
Tongue, W.	5,027 0 0
Wall, C.	5,000 0 0
Higgs and Hill, South Lambeth*	4,958 0 0
Shepherd, W. (withdrawn)	4,061 0 0

*Accepted.

(a) Cost of enlargement, including closets, £2,480; (b) cost of tar pavement and playground, £103; (c) cost of cloakrooms for entire school, £1,360; (d) cost of covered playgrounds, £250; (e) cost of teachers' rooms, £200; (f) cost of works to present buildings, £370. Special expenditure chargeable to site:—(g) new drainage for entire school, £195. Total, £4,958. Cost per head of (a), £6 4s.; total cost per head, £12 7s. 11d.]

MANNINGHAM, BRADFORD.—For the erection of stabling for 60 horses, car-shed, house, &c., at Manningham. Mr. C. S. Nelson, Albert Chambers, Park-row, Leeds, architect:—

Booth, C. and Son, Clayton, near Bradford (accepted)	
--	--

(Forty-four tenders for the whole works were received.)

MEXBOROUGH.—For erection of a wall at Castle Hill, for the town council:—

Iye, G. (accepted)	£31 8 0
--------------------	---------

NEWARK.—For alterations to the police station at Neath, for the county magistrates of Glamorgan-shire:—

Thomas, J. (accepted)	
-----------------------	--

NEWARK-ON-TRANT.—For erection of six houses in Friary-lane, Newark, for Mr. J. Gregory. Plans prepared by Mr. G. Sheppard, Newark, borough surveyor:—

Baines, C.	£293 0 0
Cressland	853 0 0
White	850 0 0
Smith and Lonn	835 0 0
Duke (accepted)	820 0 0
Combes, W.	770 0 0

NEW MALDEN.—For the erection of a villa residence on Norbiton Park Estate, New Malden, Surrey, for Mr. F. Sledge. Mr. T. L. Heward, architect. Quantities supplied:—

Worman, G.	£819 0 0
Thorn, H.	749 0 0
Saunders, J. (accepted)	747 0 0

NEW MALDEN.—For erection of bridge over Beverley Brook on Blagdon Estate, New Malden, for Messrs. Gussette, Wadman and Daw. Mr. T. L. Heward, architect:—

Pollard (accepted)	£167 0 0
--------------------	----------

NEW MALDEN.—For erection of stable and coach-house, at Ripley Villa, New Malden, for Mr. F. S. Merryweather. Mr. T. L. Heward, architect. Quantities supplied:—

Earle, J.	£120 0 0
Worman, G.	117 0 0
Saunders, J. (accepted)	91 0 0

NOTTINGHAM, W.—For the enlargement of the school in Edinburgh-road, Ladbroke-grove-road, by 400 places, for the London School Board. Mr. E. R. Robson, F.S.A., architect to the Board:—

Tongue, W.	£3,218 0 0
Rankin, J.	3,149 0 0
Higgs and Hill	3,090 0 0
Wall Bros.	3,090 0 0
O'rey, W.	2,937 0 0
Scrivenor, W., and Co.	2,905 0 0
Grover, J.	2,868 0 0
Shepherd, W.	2,808 19 0
Simpson and Co., Prompton-road*	2,773 0 0

*Accepted with addition of £50.

(a) Cost of enlargement, including closets, £2,523; (b) covered playgrounds, £250. Total, £2,773. Cost per head of (a), £6 6s.; total cost per head, £6 18s. 8d.]

POPULAR, LONDON, E.—For paving and making-up Clifton-street, Poplar:—

Trickett (accepted)	£233 0 0
---------------------	----------

READING.—For house and premises in the Bulmershe-road, for Mr. Thomas Wilson. Mr. W. Simmons, Friar-street, architect and surveyor. Quantities supplied by the architect:—

Bottrill, Kings-road (accepted)	£898 0 0
---------------------------------	----------

[Two other tenders received, for £903 18s., and £1,295 respectively.]

RICHMOND, SURREY.—For drainage works on the Halford House estate, for the select vestry:—

Sims, E., Richmond (accepted)	£94 0 0
-------------------------------	---------

SHERIFF.—For renovation of farm premises, for Sir T. W. P. Blomfield, Bart. Mr. William Tomlinson, Coventry, architect:—

Shilton, Stoke Gilding	£230 0 0
Fox Bros., Atherton	210 13 9

SOMERSET, NEAR GREAT YARMOUTH.—For additions to Blood-hills farm-house, for Mr. F. Charsley. Messrs. Bottle and Olley, Great Yarmouth, architects:—

Davey, R., Yarmouth	£452 0 0
Harbord, J., Caister	420 0 0
Wilson, W., North Walsham	392 10 0
Bartram, R., Aylesham	383 10 0
Batchelor, J., Statham	364 0 0
Went, J. H., Yarmouth	358 0 0
Cooper, T. T., Yarmouth (accepted)	328 0 0

For deep well, pump, &c., to the above:—

Norman & Son, Yarmouth (accepted)	£46 0 0
-----------------------------------	---------

SOUTHEAST-SEA.—For construction of 522 lineal yards of 12in. pipe-culvert, with manholes, &c., in London-road, Southend, for the Local Board. Mr. A. Cayton, surveyor. Quantities supplied:—

Spenslow, Southend	£240 5 4
Steward, Southend	233 15 6
Nicholson, Chelmsford	226 9 6
Wilks and Co., London	217 10 4
Strachan and Co., Wood Green*	215 16 4
Storey, Southend	162 5 1

*Accepted.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 4, 1881.

THE MARYLEBONE FEVER DENS.

WITHIN a short distance of Regent's Park, and close to the Marylebone-road, a closely-packed neighbourhood of tenements exists, which, for some years, has been suffered to become the haunt of small-pox, typhus, and other infectious diseases. As long ago as 1876 it appears these dwellings were described, in an official report, by the late Dr. Whitmore, the officer of health, as unfit for habitation, yet they have been allowed to remain, and once more threaten a populous district with an epidemic. We now refer more particularly to a number of small houses in Charles-street, Lisson-grove, some of which have recently been condemned, by the medical officer of health, owing to another outbreak of fever. A few days ago an inquiry was opened by Dr. Danford Thomas relating to the death of Mrs. Burton, the wife of a labourer, living at No. 12, Charles-street, Lisson-grove, alleged to have been caused by the insanitary condition of the house in which this family lived. This woman, her husband, and four children occupied the front kitchen of the house in question, and one of the daughters had been removed to Homerton Fever Hospital previously to the death of the mother, owing to an attack of typhus fever. Here a family of six, according to the evidence, occupied one bed in a room not fit for a cat or dog to live in, the basements standing in a mass of wet black soil, 5ft. or 6ft. in depth. Dr. Norman Kerr said he had not been out of this street for six weeks; that both the mother and daughter had been suffering from typhus of the most severe type; and that the bedding on which Mrs. Burton had been lying had not been disinfected. From the same witness we learn that the neighbourhood was saturated with the poison of the fever, and that in three houses in this street there had been no less than 19 cases of typhus fever in six months. Eight houses in the same street have been officially reported to the vestry as unfit for habitation. The district surveyor reports that the footings of some of the walls do not reach any solid foundations, though they extend 4ft. or 5ft. below the floor level; that there is no damp-course, and the damp invades not only the basements, but the first floors. Mr. Tomkins, the surveyor, expressly states in his official report: "The houses were generally in so dilapidated a condition that no structural alteration could make them habitable." In one of the four condemned houses, the back walls were much bulged and very damp; the basement-rooms were only 6ft. 3in. high, and the floors laid on the ground. We learn also that these houses are let out in tenements, as many as five persons sleeping in one room, and that the high rent of 2s. 6d. a week was paid for the wretched cell called a kitchen in which the family we have referred to dwelt. According to another authority we learn that typhus fever broke out in Charles-street in August last; there had been 30 cases, of which 14 were confined to four houses. The magistrate gave an order to vacate these four houses, pending proceedings to be taken for their destruction; but proceedings under *Torrens' Act* take time, while the fever is still at work.

When we read these statements of facts we shudder to think of the many other similar plague-spots which exist in the metropolis, the existence of which is not

brought prominently before the public, and of the numerous instances of people stricken down by diseases the real origin of which is misrepresented. Utterly disgraceful as the state of Charles-street is to our boasted sanitary progress, it will be admitted by many who have taken the pains to visit that locality, that streets and tenements many times worse are to be found in London and elsewhere, in the shadow of our palaces and cathedrals, and under the walls of our colleges and great public schools.

One of the greatest difficulties vestries and authorities have to contend against in carrying out remedial measures, is the opposition of the freeholders and owners of properties of this class, as well as in every instance the legal procedure required to carry out provisions under the various Acts, and the apathy and indifference arising from ignorance which exist among the labouring classes. We need only refer the reader to the numerously-attended meeting of the vestry of St. Marylebone, held last week, to hear appeals from the owners of certain houses in Charles-street, which had been condemned by the medical officer of health and surveyor as unfit for habitation, under the provisions of the *Artisans' and Labourers' Dwellings Act*. The reports of those gentlemen (Mr. Blyth and Mr. H. T. Tomkins, the surveyor) afforded ample ground for the vestry to put in force the powers they possess under the above Act, yet there were not wanting those who, from personal interests, objected to the demolition of these houses. The owners of several of these tenements, scarcely fit for the habitation of cattle, without denying the reports, set up a plea that they had only an interest in their leases of nine or ten years, and that it would be a hardship upon them to destroy the houses, and make them rebuild. No doubt, it is a hardship for a lessee holding for a short term to be compelled to rebuild; but the vestry have a paramount duty to fulfil in the interests of the public. The surveyor employed by the lessees differed from the parish surveyor, inasmuch as he thought structural alterations would meet the requirements, and the vestry ultimately decided that the two surveyors might be allowed a week's consultation on the subject.

After a personal inspection of this fever-haunt, we can fully justify the opinion that nothing less than reconstruction would satisfy the most ordinary conditions of public health. Charles-street is a short street leading out of Lisson-grove. The houses are chiefly brick and stucco, of two stories above ground, some of them occupying a very narrow frontage, with little or no outlet in the rear. No. 12 looks as if its foundation had yielded, for the front is not plumb, and the stucco seems in a very crumbling and dilapidated condition. An iron railing in front of the houses incloses a narrow area, and upon it, at the time of our visit, washed clothes were hung out to dry, evidence that there were no back-yards sufficient for such a purpose. A squalor-stricken aspect pervades this short street of dingy-looking houses, of which there are about 17 on each side. Each contains about six rooms, and many of these single rooms hold separate families. The interior of some of these rickety tenements is far worse than their exterior would lead one to suppose. The condemned houses are on one side of the street, and each of them contains two dirty, dismal basement-rooms about 6ft. high, in either of which it could scarcely be possible to believe that any human being could live. As for flooring, these rooms have only a few rotten boards; others, the damp earth; bare the walls, once plastered, show the white bricks, and are in a miserable, damp, and dirty state. In one instance, the floor, which had been taken up for examination, brought to light a reeking accumulation of soil saturated by sewage matter, and it was

upon such filth that the unfortunate woman and her family had lived and slept. It can hardly be imagined that such cellar-like rooms could be let as tenements. They are about 9ft. square and very low. The closets in the back yards of these houses are indescribably filthy: they are simply abominations. The upper rooms, though more habitable, are dirty and dilapidated; the stairs look very shaky, and the ceilings, floors, and walls more or less broken, and a comfortless sort of life at the best must be passed by the inmates with such wretched surroundings.

The "Report of the Dwellings Committee of the Charity Organisation Society," just issued, deals in a very direct manner with the momentous question of housing the poor, and the difficulties encountered in carrying out the provisions of the *Dwellings Acts*. It throws a good deal of light on the possibility of the very existence of such fever dens as we have been describing. The obstacle to all action in providing the working classes with suitable dwellings in the interior of London rests, as the Committee point out, on the inability to purchase for this object. Building associations are powerless to deal with corporate or private owners directly, and the only remedy is for some authority, such as the contemplated Municipality in London, or the Corporation or Metropolitan Board of Works to compel purchase of condemned property such as this for improvement, allowing compensation to the owners under arbitration; but it cannot be denied, that for capital to be available for buildings of this class the Loan Commissioners should lend at a lower rate than 4 per cent. With regard to the question of repairs, *Torrens' Act* throws the responsibility of repair chiefly on the owner, and the *Artisans' Dwellings Act* upon the local authorities. The former, as it stood in 1875, contemplated demolition of dwellings unsuited for habitation, and therefore could not be largely applied to the metropolis. It is evident also in the working of any Act, the perplexities arising out of several ownerships in one area have to be met. These have, to a certain extent it is true, been removed by the *Artisans' Dwellings Act*, 1875-79, which proposed that ill-built and densely-inhabited parts of the metropolis, where fevers and deaths were constantly taking place, should be pulled down and reconstructed, provision being made for the tenants thus displaced. The action taken under this Act has been very small in the City. The two Acts are rather conflicting. The report before us, in one of its conclusions, states: "It appears in the metropolis, owing to the different incidence of the rating and other causes, the effect of the *Artisans' Dwellings Act* of 1875 has been to weaken local responsibility and to impede action under *Torrens' Act*." The Charles-street experience has, undoubtedly, proved the truth of this remark, and we think the recommendation of the committee, that *Torrens' Act* might be enlarged so as to include a few houses not themselves uninhabitable or removable for the erection of open spaces or the opening out of alleys and courts, one deserving attention. But there are other obstacles in the way of carrying out these Acts. The present system of local government rather impedes than facilitates the removal of such neighbourhoods as we have described. The medical officers and inspectors make up a large army of sanitary officers, who have, in many cases, private practice and business to attend. The cost of acquiring cleared areas under the Acts of 1875 and 1879 for the erection of labourers' dwellings have, however, been the main obstacle in the way of improvement. A very important table is given in the report, which shows the high prices paid by associations and others for land for dwellings. Some of these are as high as 4s. 10d. and 13s. 4d. per square foot. Another table

gives the cost, per family, of providing dwellings. In central positions the average cost per family has ranged from £171 to £315; but the cost on Miss Octavia Hill's plan is about £118. It is evident that no association without special aid can make these figures remunerative. The rents charged are out of all proportion to the wages of the labourer. The very lowest estimate, as given by Mr. Gatliff, is about £52 a room, which, at 7½ per cent., would be 1s. 6d. per week; rates and taxes, ground-rent, &c., would bring it to 2s. 2d. for each room—more than the poor can afford to pay. This rent is exceeded by many. Many rooms let at 4s., and such a price can only be paid by the upper class of artisans. The value of property, the procedure under the Acts, the compensations to owners and lessees, have proved, as the report informs us, so serious a hindrance and burden on the rates, that action in London and large towns has been suspended. Land acquired at £1 1s. 8d. per foot has been sold with difficulty at 4s. 8d. per foot, and the conclusion to be drawn is easy. The wages of the working man of the lower class cannot afford to pay for clearing away costly sites at such a price, and also to provide a fair dividend on the outlay in building improved dwellings. Thus, it is very fairly contended in the report of the Minority Committee that there is no "reasonable prospect of such a reduction of this initial outlay as will ever bring the cost of central sites in the metropolis, and the dwellings erected on them, within the means of those on whose behalf the Legislature has endeavoured to intervene, and that this condition is one of increasing difficulty." The recommendations of the Committee, are the following: (1) That the scale of compensation under the Artisans' and Labourers' Dwellings Act of 1875 and 1879 should be reduced, and the mode of procedure simplified. (2) That these Acts should be converted into a Towns Improvement Act, in the application of which the needs of the labouring classes should have due consideration, but that no rigid rule should be laid down with reference to the replacing of dwellings on cleared sites. (3) That effectual means should be taken to insure the application of Torrens' Act in London, and of the Sanitary, Public Health, and Building Acts, both in London and in the suburbs. (4) That all railway companies should be required by law to run cheap workmen's trains similar to those on the Great Eastern Railway to Enfield. Every one who has watched the labours of Associations for improving the dwellings of the poor, and the very inadequate realisation of the objects they had in view; the tardy response of those classes for whom dwellings have been built, and their occupation by a class of artisans who can better afford to pay higher rents, will endorse these recommendations. We believe nothing will be done to rebuild central town sites till the Legislature reduces the compensations paid to owners for unhealthy areas. The price to be paid for such localities as that to which we have directed attention should take into account the miserable condition of the dwellings from which rents are extracted, and the price paid should be more in the nature of a fine on the owners than compensation. Such an enactment would tend to make owners more careful of their own interests and those of their tenants, and the houses would be accordingly looked after. The compulsory adoption of improved bye-laws for suburban dwellings is also one of the chief preventive measures demanded in localities which are now rapidly filling up in the suburbs, by the labouring class in search of dwellings. By such means, legislation may yet do something so arrest the disgraceful condition of the houses of the poor, and induce owners of houses to keep them in a state suited for a civilised community.

HANOVER GALLERY EXHIBITION OF PAINTINGS.

THE autumn exhibition of paintings and water-colour drawings at the Hanover Gallery, New Bond-street, opened last Saturday. C. W. Pittard, whose "Dominio Sampson" appears first in the list, has shown a decided talent for humorous caricature. Bold and vigorous in execution, in which the pigment is put on with no sparing hand, is Oliver Baker's "Derbyshire Mill." The colour is natural. A well-painted distance is given by Geo. Bassett, "On the Elen, Westmoreland." Quite Burne-Jonesian in style is Albert Besnard's "Sweetness." The face is more indicative of misery than sweetness, and the ideal of the painter is evidently borrowed from that intense realism of the ascetic side of life, which the disciples of "high art" affect. The features and hands, by the way, are very delicate, and the face belongs to one of those beings which are too unearthly to be human. The same artist's "Sorrow," a full-length figure of a woman draped in a long black robe, is another conception in the same vein. The woman's hand clutches her heart and has inflicted a deadly wound, from which the blood has poured into a pool at her feet. The idea is too sanguinary and painfully realistic to meet with admirers, and we turn to other pictures. "The Market Boat, Venice," by W. Henry, is pleasing in subject and colour. T. Whittle's picture of "Our Saxon Forefathers in a Pleasure Boat" is crude, and we pass on to notice J. W. Bottomley's "Driving Home" as a well-studied group of cattle. "On the Tummel, Perthshire," by Robt. Harwood, is a very pleasant autumnal landscape. The distant mountains and the yellow foliage which overshadow the stream are effectively painted; and near it we mark "Alderney Cows," a clever study (20). "In Maiden Meditation" (21)—R. Macchell seems to us spoiled from the fact that the artist has injured his subject by the crowded and garish accessories of the room. The mantelpiece with timepiece and other ornaments is faulty in drawing, and the composition and colour are wanting in repose. The best part of the picture is the light which falls upon the delicate china service on the table. F. Tully Lott's "Canterbury Cathedral from the Stour" is pretty; the distance and old gabled houses facing the river are carefully painted. No. 25, "A Diana of the 16th century" is a well-executed study, and the features and dress are painted with much expression and care.

Many pictures of incident are hung. We notice J. Cayton Adams's "Waiting for a Bite," a fresh-looking study; E. J. Broughton's "Confirmation" (32)—three young girls at the altar, the fault of which is a stiffness in the drapery, but it is otherwise feelingly painted; W. M. Egle's "Grace," a prim little girl with hands clasped at the table dressed in a Dolly Varden cap, noticeable for the transparent flesh tints and finished execution. The dark green tapestry background and dado are in good keeping. F. A. Verner's Canadian picture (31) is bold in its masses of water and foliage, but the touch is heavy; T. Ireland's "September Morning" is truthful and freshly painted; and H. Caffieri is the exhibitor of two or three of his charming bright woodland pieces. "Morning in June," a study of a birch glade with children, is springlike, and we never tire of the light sunny effects of this master of foliage in its brighter aspects. The light of the sky is produced, as in all his pieces, by a skilful dappling of white pigment on the green, a mode of handling productive of very soft aerial effects. No. 85, "Misty Morning," is full of soft misty sunlight, and both are thoroughly French in feeling.

Among figure studies we must mention

Rosa Koberwein's ideal face amidst a shady folial background (43); the expression is sweet, though we think hardly an embodiment of the poet's lines which seem to have suggested the theme. The most remarkable picture, probably after that of "Sorrow," is Margaret L. Hooper's imaginative canvas "Twilight—Our Lady of Oblivion" (58). The conception is thoroughly poetical, and the face and drapery of the tall, life-size figure, which is painted in the dark, sombre hue of night, are unmistakably those which we have seen in Mr. Burne-Jones's ideal pictures. The drapery of a blueish green and the background of funeral pines, are strikingly conventional—to bestow no higher praise. "A Modern Sibyl" is another clever subject by the same artist, evincing power. We must also note on the same wall some very pleasing landscapes and subjects of incident. "Dutch Boats," by C. Thornley, is pleasantly grouped; "Will-o'-the-Wisp" (45), by O. P. Yglesias, is equal to the artist's former work—the mist and impasto handling are skilful; "Easter Tide on a Welsh Stream" (65), by H. Howard, is a conscientious transcript of Nature; "French Poppies" is boldly painted with a depth of tone in background which reminds us of an old canvas. There is a little crudeness about Ellen Conolly's "Village Smithy," though the rendering of the forged iron is admirable. A very singular piece of technical execution is J. H. Pollen's "Genoa from the Land" (78), also "Florence" (117). The canvas is unprepared, and the pigments are put on the rough texture, producing the peculiar effect of a coloured crayon drawing a little way off. The surface presents a dead absorbent appearance, more conducive to effect at a distance. A. Heleke's "Showery Weather" is a freshly-painted bit of common, and A. Durer Lucas's "Wild Heath" for finished execution surpasses anything in the gallery. The same artist sends "Blackberry" (106) and an ivory fan, with the seasons and months emblematically represented by miniatures of wild flowers, both delicate *morceaux* of execution and finish. John R. Dicksee, in "Alice Lee Woodstock," shows a happy rendering of an age which artists delight to portray. Leonard Cattermole's "Pass in the Corner" is decorative in conception and colour, and clever; and we must not forget to mention the charming sketches by Clara Montalba (136, 142, 143); Matthew E. Hale's well-drawn and chastely coloured face, "Modesty," especially the same artist's skilful and masterly portrait of a lady, her face shaded in a large black brimmed hat and white frilling, and entitled "Patience." Both are ideal studies of womanhood, and are painted with feeling and power. A few other pictures of merit strike us in Nos. 142, 143, 146, 151, 153. H. T. Schäfer sends a pleasing *genre* subject "Sea Breezes"; No. 144 is pretty; No. 80 is fresh, and 77 may be looked at. One of the smaller pictures of simple incident which merits attention for feeling and colour, is No. 109, by James E. Christie, a little girl in a poppy field. A vigorously-painted picture, and dramatically told incident, is by A. Ballin (153), but is too black in its shadows to be ranked as a gallery picture. It is to be regretted such studies as No. 40, 279, 282, 283 have been hung.

In the water-colours, we can only glance at a few drawings. "Roses," by Emily Jackson, is crisp and truthful in colour. "Confidential" (175), by C. J. Lewis, two girls on a rustic bridge; and Rosalie, W. Watson's sentimental bit of apple blossom and a pair of youthful lovers, go together.

We single out an architectural sketch of "Innholder's Hall, College-street," by Charles J. Watson, a clever bit of old London street architecture; a view of "Lincoln" (230), by Andrew B. Donaldson, in that

artist's hard and conventional style of colouring; "Antwerp Cathedral," by Miss Deane (234); and "St. Jacques, Dieppe," by Lennard Lewis; the last shows some interesting work, and the colouring is transparent. A rather washed-out effect is given in Max Ludby's "Early Spring." Mrs. Paul Naftel contributes a small Welsh sketch, which is skied (246), and we may refer in commendation to a sketch by Miss Deane (248), an old Inn-yard at Bacharach, by J. D. Barnett; a sunny sketch in the New Forest, by Miss Kate Prentice; a hold drawing of a Cornish Valley (305), by Henry Bailey; Linnie Watt's "Blossom," also Nos. 326, 330, 322, &c. A large historical drawing by Andrew B. Donaldson represents "The Expiation of King Henry V. for the Soul of Richard II." There is undoubted skill shown in this curious Mediæval composition, and the drawing and colour are in strict harmony with the theme. We cannot leave the gallery without bestowing high praise on a terra-cotta bust of an Italian boy by Henrietta S. Montalba, a sister of the talented painter, and Geo. H. Saul's marble medallions, representing Night and Morning, are able contributions to the sculpture.

THE WATER QUESTION.—XX.

FLOOD-REGULATION AND WATER-STORAGE.

TO stand in the middle of an extensive valley, by the river, and consider how the injurious effects can be prevented, any reservoir for that purpose would seem to need to be preposterously large, to have any effect there. But that is not the point from which the question should be regarded; it would be beginning at the wrong end; rather, let every thousand acres downwards from the watershed be considered separately or at most in areas of a few thousand acres together, and making sure provision for the floods of each, proceed step by step towards the middle and lower portion of the valley. It is said that in France this question has been discussed since the year 1856 with regard to the valleys of the Seine, the Rhone, the Loire, and the Garonne (*vide* Foreign Abstracts, Min. Proc. Inst.C.E., Vol. LXVI., "On the insufficiency of reservoirs for diminishing the danger of floods," by M. Gros), and that in the case of the Garonne a reservoir capacity of 720,000,000 cubic yards would be required "to protect Toulouse" from a flood similar to one which occurred there in 1875, and the conclusion is that the reservoirs which had been proposed for providing against floods in these vast areas must be abandoned. No doubt the French engineers have sufficient reason for coming to this conclusion, on this scale of things. The Seine, as appears upon a geographical map of France, is 400 miles long, and drains 30,000 square miles; the Loire is 530 miles long, and drains 45,000 square miles, and the Garonne is 300 miles, draining 32,000 square miles, and the Rhone 35,000 square miles in France besides a further tract in Switzerland; indeed, these four rivers appear to drain about two-thirds of the whole country. But for the purposes of river-conservancy in England the requirements are less grand. Here we have in England and Wales but 57,800 square miles altogether, divided into 211 distinct watershed areas or river basins. Many of these, however, are not injuriously affected by floods. The number is made up of 54 draining 7,046 square miles towards the south coast, being an average of 130 square miles; 30 draining towards the east coast, an area of 16,084 square miles, the average being 536; 29 draining towards the north-east coast, an area of 13,291 square miles, being an average of 457; 17 towards the north-west coast, draining an area of 2,345 square miles, or an average of 133; and 81

on the west coast draining 19,029 square miles, or an average of 236 square miles each. Even these are large areas, and a thousand or two thousand acres is a very small part of some of them, and the regulation of the flow off the ground of excessive rainfalls on any such area would do but little to mitigate the effects of floods in the lower part of such large areas. But it stands good for its own position, and if it deals with floods upon its own area it is an effectual work, so far; and the effect may be extended downwards to any distance to which favourable sites extend.

Referring to the example last given of a regulating dam made separately, if it cost £10 an acre it would be an expensive work, for at 5 per cent. interest it would be equivalent to a yearly contribution of 10s. per acre towards getting rid of the floods in the lower part of the valley, which, being made, it would entirely prevent in proportion to its own area. But a separate dam to be made for a drainage area of 1,000 acres only, and costing £10,000, would be an extreme case in point of expense, and we have purposely adduced it for that reason. Where the provision for regulating floods can be combined with a useful reservoir the expense would be very much less. An example has been given of a reservoir and of a regulating dam, each made separately, the reservoir to contain 46,000,000 cubic feet for a drainage area of 2,000 acres where the average annual rainfall is 33in., and the dam to contain 12,000,000 cubic feet per thousand acres of the drainage area irrespective of annual rainfall. Let an example now be taken in which the two are combined: The rainstorm producing 4in. in depth of water, of which a quantity equivalent to 3in. in depth might flow into the regulating dam in a short time, was taken in the preceding examples as proceeding from 1,000 acres of ground, but it might extend over the whole 2,000 acres taken as the drainage area in the example of the reservoir, and in that case 24,000,000 cubic feet of water would have to be provided for in addition to the 46,000,000 of the reservoir, making together 70,000,000 cubic feet. This would be impounded by an embankment 70ft. high.

The quantities of earthwork in embankments of different heights on the same site are proportionate to the cubes of the heights, if to the height of the bank itself be added a height equal to the width of the top of the bank divided by the ratios of the two slopes added together; thus, if the slopes are 3 to 1 and 2 to 1 respectively inside and outside, and the top width of the bank is 20ft.,

$\frac{20}{3+2} = 4\text{ft.}$ to be added to the actual height of the embankment to find the apex in which the prolongation of the two slopes

would meet, and to which point the height is to be measured. Fig. 1 being a cross section, and Fig. 2 a longitudinal section of an embankment, the cubic contents are—

$$\frac{L \times H \times (w + w')}{2 \times 3}$$

In many embankments some part of the

ground towards the middle of the bank is more or less flat, but for the purpose of comparing the quantities of earthwork in embankments of different heights, the side slopes may be assumed to meet in a point, somewhat lower than the actual surface of the ground at the middle of the bank. If there are on a particular site 80,860 cubic yards in an embankment 60ft. high above this point, there would be in one 70ft. high—adding in each case 4ft. for the apex—

$(64)^3 : (74)^3 :: 80,860 : 125,000$ cubic yards, and, deducting the puddle wall, the embankment would be 116,000 cubic yards, for a storage-room of 46,000,000 cubic feet, with the addition of a space of 24,000,000 cubic feet to receive a flood from 2,000 acres.

The water coming into the 46,000,000 c. ft. space would be discharged by the same valves and in the same manner as has been described, the only difference being that the valve tower would be 10ft. higher, and the water which would rise into the upper space of 24,000,000 cubic feet would be discharged by a separate sluice, nearer the end of the bank, at the level at which the waste weir would otherwise be laid, and by the same means as was before described for a separate dam, there being for this discharge a separate culvert; and it might advantageously be placed near that end of the embankment at which the byewash would be made, and might discharge into it. The sill of the sluice would be laid at a depth of 10ft. below the assumed top-water level of the flood space, leaving the lower space, or reservoir proper, intact; but the invert of the culvert should be laid a foot lower. In the other case the height of the sluice-opening was described to be greater than the width; in this one the width should be the greater, and it may conveniently be made twice the height.

In this reservoir there would be a depth of 10ft. above the level, which would otherwise be the top-water level, to contain a flood, instead of its running away over the waste weir otherwise provided at the height which allows 46,000,000 cubic feet of water to accumulate before any passes over it. The top-water level is 10ft. higher, and the top of the bank is 6ft. higher still. This provision of 24,000,000 cubic feet of space for a flood stands instead of the provision of a waste weir and byewash, which, logically, are unnecessary. But to run no risk let them be provided, although they will not be required, in all probability. But they need not be so capacious as if no such flood-space were provided. Let them be of half the capacity. The estimate would then stand thus:—

	Quantity.	Price.	
		s. d. £	
Clearing the seat of the embankment	15,600 sq. yd.	0 2	130
Excavation of the puddle trench	13,000 c. yd.	5 0	3,250
Clay puddle	22,000 "	2 6	750
Embankment	116,000 "	1 6	8,700
Load on top of embankment	1,000 sq. yd.	2 0	100
Covering the inner slope with stone	9,000 "	2 0	900
Soiling the outer slope	7,200 "	0 2	60
Excavation for culverts and valve-tower	5,600 c. yd.	4 0	1,000
Ditto for byewash	2,000 "	1 0	100
Concrete in foundations	500 "	6 0	150
Ditto in byewash	1,200 "	7 0	420
Brickwork in culverts and valve-tower	"	21 0	1680
Gravel puddle	30 "	4 0	160
Stone sills, caps, coping, &c. ..	1,200 c. ft.	2 0	120
Valves, sluice, and other ironwork ..			300
Footbridge			200
Gauge-weir			100
			19,520
Contingencies			1,980
			21,500
Land and fencing			6,500
			£28,000

Adding to this a sum of £3,000 for expenses other than those of works and land, the cost of the combined reservoir and regulating dam in this situation would be £31,000, and deducting the cost of the

reservoir alone, as found before—viz., £22,000, the cost of the provision for floods thus combined with a storage reservoir would be £1 10s. per acre, or equivalent to a yearly contribution, at 5 per cent., of 4s. 6d. per acre.

Thirty-three inches annual rainfall, adopted in the example of a storage reservoir, is not far from the average of the whole of England and Wales, but the average of the upper and middle portions of the river basins is greater. The work about which these general remarks are made can be practically dealt with in no other way than by taking each case as it arises with its attendant circumstances; but we may give one other example, with a more extended area and a greater rainfall, where the area is 3,000 acres or a little more, and the average annual rainfall is a third greater than that before assumed, i.e., where it is 41in. Here the mean of three consecutive years of least rainfall would be about 36in., and deducting 12in. for evaporation, &c., the available annual depth is 24in. This yields, by means of a reservoir, a daily quantity the year round of 720,000 cubic feet. If one third be discharged into the stream there are left for supply 480,000 cubic feet per day, or 3,000,000 gallons.

Where there is this amount of rainfall there will probably be a greater number of wet days than where the amount is but 33in., and the number of days' supply the reservoir should hold would therefore be less. Let it be assumed that 150 days would be in this case the proper length of time during which the storage must be depended upon. This would indicate a reservoir capacity of 108,000,000 cubic feet. If the same proportions be followed as before, this quantity would be contained in a reservoir having a depth of 72ft. at the site of the embankment; but let the depth be taken at 4ft., and the height of the bank at 80ft. The top width of the other banks is assumed to be 20ft.; in this one let the top width be 24ft., or if the 20ft. be retained, let the quantity of earth equivalent to the extra 4ft. be added in benches on the outer slope. The embankment would then contain, after deducting the puddle wall, 174,000 cubic yards, and the estimate for this reservoir would be as follows:—

	Quantity.	Price.	
Clearing the seat of the embankment	21,600 sq. yd.	s. d. £	0 2 140
Excavation of the puddle trench	20,400 c. yd.	5 0	5,100
Clay puddle	32,400 "	2 6	4,050
Embankment	174,000 "	1 6	13,950
Road on top of embankment	1,200 sq. yd.	2 0	120
Covering the inner slope with stone	13,000 "	2 0	1,300
Soiling the outer slope	9,600 "	0 2	50
Excavation for culvert and valve tower	5,500 c. yd.	4 0	1,100
Ditto for brewash	6,000 "	1 0	300
Concrete in foundations	550 "	6 0	165
Ditto in brewash	3,230 "	7 0	1,120
Brickwork in culvert and valve tower	1,050 "	24 0	1,200
Gravel puddle	300 "	4 0	180
Stone sills, caps, coping, &c.	2,000 c. ft.	2 0	200
Valves, &c.			270
Footbridge			230
Gauge weir			200
			28,845
Contingencies			2,855
			31,700
Land and fencing			9,300
			£41,000

To this, for other expenses than those of works and land, let £1,000 be added, making £45,000. This, for a storage of 108,000,000 cubic feet, would be about £420 per million.

To complete the form in which we desire to put this question of water-storage combined with flood-regulation, let now 21,000,000 cubic feet of space be added to this reservoir, which is assumed to be of suitable capacity for an area of 3,000 acres and an average annual rainfall of 41in.; while at the same time it is assumed that one rainstorm in any district of a few square

miles amounts to 4in. in depth over an area of 2,000 acres only; and that, of this depth, three-fourths run directly off the ground, making 24,000,000 to be added to 108,000,000, or together requiring a space of 132,000,000 cubic feet. This would be impounded by an embankment 86ft. high, which would contain, after deducting the puddle wall, 214,000 cubic yards, and the whole cost of this reservoir, with the addition of the flood space above mentioned, would be £15,000 for works and lands, to which may be added £5,000, making £50,000. This reservoir would equalise and render useful the streams of 3,000 acres of ground, and the addition of the flood space would protect that area from any demand for contribution towards the funds of a river conservancy board. If the supply of water from the reservoir—viz., 3,000,000 gallons per day, pays for its construction and attendant expenses, the cost of this flood protection would be very small, being £5,000 for 3,000 acres.

SHOP WINDOWS.—III.

(Continued from page 554.)

THE manufacture of glass has made rapid strides since the abolition of the duty upon it. Prior to 1845 there was little enough inducement to try experiments in the development of new processes, as the duty was levied, not on the perfect glass that left the oven, but on the material that entered it, much of which was destroyed or rendered useless in the firing. Some thirty years ago the Bohemian glass was considered the "ne plus ultra" of vitreous art, and was the admiration of the connoisseurs of the day. Now it is almost out of date; and few—among, at any rate, the more æsthetic portion of the community—would care to see it about their houses. The removal of the duty gave a sudden impetus to the English glass-works, and science and ingenuity combined soon effected an entire transformation in its production and treatment. While the material itself remained expensive, the articles were heavy both in form and substance, and a large amount of labour was bestowed upon cutting, the only form of embellishment then practised. Now, nearly all glass-ware is made as light and delicate as is consistent with the necessary strength—sometimes, indeed, far less so, as housekeepers with careless servants know to their cost—and, when ornamented at all, is, usually, either moulded, engraved, or etched with hydrofluoric acid. Cut glass, however, is by no means defunct, and we should be sorry it should become so. While sacrificing one characteristic of the best glass, viz., its perfect transparency, cutting increases its brilliancy, and brings into play the prismatic refraction, which imparts to it an additional lustre. The best cut glass of the present day is perhaps that of Osler, of Birmingham, especially in its application to chandeliers; but there is a great tendency to overdo this treatment, and we not unfrequently come across glass-cutting run simply mad.

Much of the modern table-glass is extremely elegant, and wine-glasses may easily be selected the stems of which, with ordinary care, do not readily "unscrew." The plain specimens depend for their effect upon the purity of the material employed and the chaste outlines of their form, aided, perhaps, by artistic modelling, or applied work. When surface-decoration steps in, we no longer find it comprised in sprawling fern-leaves and idiotic scrolls; but each article receives a well-considered form of embellishment, whether it be a simple border neatly etched upon a tenpenny wine-glass, or the richly-engraved arabesques upon decanters at so many guineas a-piece. In this, as in many other branches of manu-

facture, the English are now "facile princeps," and we trust they may long continue so.

The revival of the old Venetian glass by Dr. Salvati, at his factory on the Lagoon, is noticeable, not only in itself, but for its influence upon British make. Salvati's glass best combines many of the beauties and many of the defects of its ancient prototype. Quaint in design, rich in the colouring of certain portions, and opalescent in others, unconventional (if we may use such a term for want of a better) in its texture, and bearing the unmistakable impress of individual handiwork; its quaintness, nevertheless, often merges into extravagance, and its details frequently outrage all propriety of treatment as shamelessly as the east iron and Dresden china of which we have already spoken.

The Venetian glass has had an unmistakable influence upon the modern English; but the latter, if wanting in the bold invention and artistic feeling that characterises most of the Murano products, is also free from their vagaries and defects.

We have not the space to enter into an exhaustive notice of stained glass, and we shall, therefore, add nothing to what we have already said about it in dealing with decorative materials. But plate-glass demands a word or two. We can by no means look upon this material as an unmixed blessing. True, it is a comfort to be able to look at our neighbours across the street, or at the hills across the valley, without the distortion created by the old crown, and, to a lesser extent, by the more modern sheet-glass. But plate-glass has had a most baneful influence, not only on shop-windows, but (in the form of the huge mirrors) on half the drawing-rooms in England. In fact, this very material gave rise to an almost interminable feud between two men no less cultivated than Sir Charles Barry and Prince Albert, the latter of whom conceived the astounding idea of lining the House of Lords with looking-glass! Fortunately, Sir Charles' artistic and independent spirit carried the day, and saved us from being the laughing-stock of Europe—though at an immense sacrifice to him of Court influence and legitimate emolument. The great development of stained glass has, however, somewhat moderated the excessive rage for plate; and we may, therefore, hope to see its use confined by degrees within more reasonable limits.

The jeweller's handiwork is one legitimately within our ken, and, like the silversmith's, it has not kept pace with many others in improved taste.

To speak generally, we may look in vain among the London shops for the exquisitely beautiful specimens of the goldsmith's art that greet us in Continental towns; and although as regards finish, our English work is probably superior to most of the foreign, it is, nevertheless, singularly unimaginative. At some of the first jewellers are occasionally to be seen very lovely articles, and we have lately observed some highly artistic settings of pearls, with topaz, onyx, or amethyst. But the brooches, bracelets, locketts, and scarf-pins of the usual types, though delicately worked, evince a sad poverty of invention, and are anything but worthy of our times. We are glad to note an increasing use of the last-named gem. Among the less costly jewels the amethyst is one of the largest and most beautiful, and its rich purple colour contrasts perfectly with dead gold. When thus set—especially if relieved by pearls or white enamel—it forms as lovely an ornament as we can call to mind.

The demonetisation of silver has thrown vast quantities of this metal into the market at a reduced value, and hence has grown up the present large manufacture of silver ornaments. These, as a rule, are far more elegant

than those of proportionate cost in gold, the Birmingham necklets in particular, with pierced or fretted links, and some of the bracelets, being particularly charming. Much of the chasing, too, though not always in the best taste, seems to receive more attention than that of articles in gold. How far this may be due to an antiquated, though still prevailing, notion that gold, from its greater intrinsic value, must necessarily be—without reference to its artistic treatment—a greater personal adornment than silver, we cannot say. But the fact remains, that in silver the average of ornaments are better treated than in gold.

We need hardly speak of diamonds, emeralds, and rubies, as it is on a very small scale only that they figure in shop-windows; but some of the best kinds of low-priced "jewellery" are articles which, really, are not jewellery at all. The Scotch treatment of parti-coloured pebbles (and, occasionally, of real gems) in a silver setting, is frequently most effective. The blues and reds of the Roman mosaics, with their minute tessere, often lend themselves most happily to the completion of a lady's toilette, and we have been particularly struck at Whitby by brooches of Florentine mosaic delicately mounted in jet. All these, like cameo brooches and pins (which are now almost invariably set with quiet, good taste), possess the twofold merit of comparative cheapness and considerable refinement, and indicate in the wearer a higher notion of the æsthetic than the more expensive and pretentious articles of plain gold. Of aluminium it should not be our cue to speak; but its introduction has had no beneficial influence on morality in dress. Cleverly as it is manipulated, and often difficult to distinguish from gold, it is simply a lie, and as such is as objectionable as the gold-plated shams and imitation jewels of the Palais Royale. Better far, for those of slender means, the brass or leaden ornaments that one sometimes sees abroad, than such deceitful rubbish! Still, with the ever-increasing love of display, and the demand for what is cheap and nasty, it is not likely that the manufacturers will cease to flood the market with what commands a sale.

However much we may extol the improvement in taste and design in most branches of manufacture, we regret to find a great falling off in make and quality, and this most notably in textile fabrics. Where shall we meet with the materials for a sheet such as we lately saw in use, marked 1827? Or where the fine and delicate napery that once passed from mother to daughter through successive generations? The good old English term of "spinster" has ceased to have a significance, and become the absurdest of anomalies. Instead of the ample equipment with the household linen, made from time to time, and as a marriage dowry, by the deft and delicate fingers of those who were in time to become the mothers of our future gentlemen—linen that was literally "laid up in lavender" when not in actual use—we find, in many a pretentious house, a beggarly complement of articles from the Tottenham Court-road, that, by a stroke of good luck, and the blessing of a careful washerwoman, are fortunate if they last a twelvemonth without renewal or repair! Carpets, upholstery materials, and those handled by the milliner and dressmaker, have all shared the same fate. This deterioration is, no doubt, mainly attributable to the increased demand for cheapness and variety. Within certain limits this demand is a natural and healthy one; and its satisfaction affords to many the means of possessing things that would have been impossible to them a generation ago. But we are decidedly of opinion that the proper limits have been exceeded; and we think it behoves our leading manufacturers to set an example of en-

deavouring to stem the tide of inferior production, before its effects become seriously disastrous to our commercial morality and reputation.

Though not strictly within the scope, perhaps, of a professional paper, there is one more matter on which a few brief and concluding remarks may not be quite out of place while upon a subject such as we have been dealing with—viz., the arrangement of wares in shop-windows for the purpose of display, or, as it is technically termed by tradesmen, "window-dressing." This is an art of which the principles seem very little understood, but which is equally important as regards the improvement of public taste, and the emolument of the vendors. In an article on "Shop-Fronts" we spoke, some time ago, of some of the evils attendant on the enormous shops now so common; but there exists yet another in the greatly increased difficulty of dressing these huge interminable windows. Every stage-manager knows the difference between preparing a spectacle for such boards as those of "Covent Garden" or "La Scala," and those of the "Prince of Wales's" or "The Court." The same thing applies to shop-windows. The larger they are the more difficult, and, therefore, the worse, is their dressing. We could name many of the smaller drapers or milliners, for instance, whose windows are always elegantly set out; but those of the largest drapery establishments are nearly all so many editions of chaos. This is not to be wondered at; for the principal, whatever be his own taste and skill, can hardly devote much of his personal attention to the tedious and laborious work of filling these acres of plate-glass. This task is consequently left to shopmen, who cannot be expected to possess the feeling for form and colour, the knowledge of analogy and contrast, and the experience in grouping and general arrangement, that are imperatively necessary for success in such a task. Hence we find in one establishment, walnut loobles supporting iron bedsteads or easy chairs; in another, expensive velvets festooned over coal-scuttles; in a third, Brittany butter and Brummagem hardware fraternising with a touching sympathy. If we turn to a large drapery house, we shall meet with mantles, bonnets, petticoats, and gloves, all elbowing each other in a hopeless confusion, that becomes still worse confounded by yards of lace and ribbon, and bales of silk poised upon each other like the structures that our children build with their box of bricks. Sunshades open, sunshades shut, sunshades topsy-turvy, and sunshades dangling from the gas brackets or stuck into their chimneys—each one in an attitude different from its brother (or perhaps we should say its sister)—distract the eye, and drive one nearly crazy. In some of the best-kept windows we may find a distinct and leading idea, carried out with ability and refinement. This breadth and unity of treatment is somewhat a speciality of Bond-street, where we notice a "tone" in the window-dressing, wholly distinct from, and much superior to, that of most other streets, at least in this country. Not long ago our attention was arrested here by some fifteen or twenty immaculate shirt-fronts, placed with mathematical precision between as many crumpled handkerchiefs of dark blue silk; and we have seen a most effective display of nothing more attractive in themselves than bilious-coloured yellow stockings that would have gladdened Malvolio's heart. A chemist's shop is not an establishment calculated to inspire one with a fierce enthusiasm; but, in trimly-arranged windows, a choice collection of black draughts becomes almost as appetising as the bundles of asparagus and baskets of strawberries, arranged with equal symmetry at the leading fruiterers'. The small articles dealt with in such busi-

nesses as the chemist's, the watchmaker's, the bookseller's, and the Italian warehouseman's should be placed together in such numbers, with such regularity, and of so similar an appearance as to form them into large groups; and a few only of such groups should be exhibited at once. By such means the same repose and breadth are attained, as in the display of a single inlaid cabinet or a couple of embroidered ball-dresses. Foremost in the arrangement of the goods displayed in their respective windows are, naturally, the best decorators, and some of these gentlemen's displays afford a gratuitous lesson in taste that is well worth learning.

A few words will suffice to sum up what we have said on window-dressing. The window should be no larger than is necessary, and should never be overcrowded. There should be one leading idea in each successive display, which should be rigorously adhered to. All the best work in the higher branches of art has been thus characterised. When Handel sat down to write a chorus, he knew what he wanted to do, and did it. It was the same with the best of Shakespeare's plays; it is the same now with Mr. Millais', or Mr. Poynter's portraits. Even the world-famed Yankee pill was true to these traditions, for it "attended strictly to business, and never went fooling about." When the articles to be exhibited are large, a very few should be placed in the window at the same time; when they are small, they should be grouped into masses with unflinching regularity. Harmonies of analogy are generally more suitable for the purpose in view than those of contrast; but when the latter are employed at all, they should be used boldly, though sparingly. Lastly, it should be borne in mind that to distract and tire the eye is to defeat the very first object of all shop-windows, and that a distinctly set intention, carried out with simplicity, uniformity, breadth of treatment, and repose, is the one great essential of effective display.* J. G. LIBRA.

CONVERSAZIONE OF THE ARCHITECTURAL ASSOCIATION.

THE 40th session of this Association was inaugurated on Friday evening by a conversation, held at 9, Conduit-street, W. The attendance of members and lady friends was very numerous, but the cloak-room and refreshment arrangements showed considerable improvement on previous years, and the inconveniences of a crowded assembly were minimised. The exhibitions of pictures and needlework usually occupying the walls of the lower galleries at this period of the year were absent, giving the committee better scope for the display of loan exhibits. These included in the east gallery, a large display of water-colour sketches from Norfolk and the Northern Counties, executed by Mr. R. Phené Spiers during a summer tour; others by Mr. F. A. Powell, from the neighbourhood of Laon and Troyes; rough cartoons for wall decoration and for stained glass, by Mr. H. Walter Lonsdale; elevations and sections of Famagosta Cathedral, Cyprus; and a well-arranged and choice collection of Eastern armour and faience, the results of a tour by Mr. Sydney Vacher; design for panel decoration, made by Mr. E. Moore, for Mr. P. Anson. Messrs. Liberty and Co. showed examples of Indian silk and embroidery for portière, Japanese cabinets, with fretwork and lacquered panels, executed by Mr. C. Bevan, and a Chinese cabinet, all containing specimens of Kishni and Satsuma ware; Messrs. Gillow and Co. lent cabinets in the Italian style; Messrs. Gregory and Co. some Turkoman curtains, arranged by Mr. W. P. Collins, from examples in Persian MSS.; the Artists' Furnishers' Alliance cabinets, and reproductions of door-furniture and other metalwork, by Dr. Dresser; and Messrs. Doulton

* We desire to correct a misstatement that we made in our last article respecting Mr. Balm's French paper-hangings. His London agent informs us that the prices of these goods have recently been reduced by something like 50 per cent., and that they are now the cheapest high-class papers to be found anywhere in the market.

and Co. had a stall of their Dou'lon ware and faience. In the west gallery the chief features of interest were the sketches executed during the recent A. A. excursion in Worcestershire, by Messrs. W. H. Lynn, R. H. A., Aston Webb, John Johnson, and Maurice B. Adams; and the photographs taken at the same time by Mr. J. L. Robinson. Some of these photos were mounted in a novel manner, introduced by Messrs. Millard and Robinson; the proofs are floated in a bath of gelatine, and then laid face downwards on the glass, the air being carefully excluded; the whole space at the back is then tinted with an even wash of any suitable coat of oil-colour. By this means the prints are rendered permanent. In those exhibited the margins were sage green, giving an opalescent effect.

At nine o'clock the meeting-room of the Institute was densely crowded, as Mr. Aston Webb was to inaugurate his duties as President for the session, by the

DISTRIBUTION OF PRIZES.

The proceedings commenced by the award, for the first time, of the Architectural Association travelling studentship, consisting of a silver medal and a cheque for £20, which was taken by Henry H. Kemp; second prize, bronze medal and two guineas, F. G. F. Hooper; third prize, bronze medal, W. A. Pite. The Essay Prize was taken by A. T. Ellison. The Architectural Union Medal and Prize had not, the President announced, been awarded, the only set of measured drawings not being considered up to the standard. In the Class of Design, W. Leverton took the first, G. W. Ward the second prize, and E. D. Pickford received hon. mention. In the Elementary Class of Design the first and second prizes were equally divided between W. G. Lander and C. Danch. In the Class of Construction W. A. Pole obtained the first, and W. J. Lander the second prize, and C. Danch hon. mention. In the Colour Class J. N. Nice took the prize. The premiated drawings were hung on the walls of this room. Immediately after the distribution, Mr. Webb delivered the

PRESIDENT'S ADDRESS.

He congratulated the members and guests on the fact that, since they last assembled in that room, the progress of the Association had been satisfactory in almost every way. The session would be memorable on account of the foundation of the first studentship attached to it. Their late President, Mr. Ernest C. Lee, announced the proposal on the occasion of the last *convocation*. The movement was heartily taken up by the members, nearly £700 being promised, and its success assured. Before the session was over, Mr. Lee had the satisfaction of awarding the first travelling studentship to Mr. H. H. Kemp, who had that evening received the medal, and the result of his trip might be seen on the walls, in a series of sketches which, he thought, had set a very high standard to future students. The classes had been well attended during the session, and the prizes keenly competed for, although the open prizes were but poorly supported. They had lost, during the year, a great friend to the Association in Mr. William Burges, A.R.A., who had left to young men an example of great thoroughness in work, strict integrity, and a high standard of professional honour. But a new session was before them, and they had now to consider how, with increasing numbers, they could best augment the usefulness of the Association, and meet the enlarged demands made upon it. Mr. J. D. Mathews, their treasurer, had suggested a course of lectures, so arranged in conjunction with the classes, as to assist those preparing for the compulsory examination of the Institute. The proposal had been met with the support of Professor Roger Smith, and would be carried out, the services of Messrs. Blashill and Tarver having been obtained. The lectures would be a very important departure from the system of mutual help and instruction on which the Association had hitherto been worked; but, like all other foundations, if the Association would continue its usefulness, it must conform to the altered conditions and requirements of the times. But the student must not think that the Association could provide him with all the education required in conjunction with his office work. He should still avail himself, in addition, of some of the many other opportunities for instruction open to archite-

tural students in London—viz., the Architectural School at the Academy, with Mr. R. Phené Spiers as master, and the valuable Academy lectures; the courses of lectures at University and King's Colleges; the South Kensington Museum and reading-room; the Architectural Museum; and the Institute library. The student was, indeed, never so well supplied with means of improvement as at present. Still, there was a lack of completeness and cohesion amongst these means of education, which somewhat detracted from their general usefulness. A strong head was needed to gather up the threads and work them into a comprehensive scheme, so as to systematise them into a complete plan of education. The Architectural Museum, for instance, containing, as it did, an invaluable collection of casts, languished sadly in Tufton-street, whereas, in a more accessible position, its usefulness might be largely increased. Some day, perhaps, they might see a united attempt made towards the foundation of an Architectural College, where their societies might be properly housed, and their students, assisted by the professors of the college, could pass through a course of systematic study, say, for two years, passing then to an architect's office, and finishing up with a one or two years' trip on the Continent previous to entering on the real business of life. But these were only dreams, and he feared, a long way from fulfilment. At the commencement of a new architectural year, members of the profession asked themselves what they were aiming at and working for, what development they had made, and how far they had advanced towards the attainment of a style distinctive of our own day. The search for a new style seemed like the old search for the philosopher's stone—hard to find, and doubtful if it could be found, while some would go so far as to think that, if found, it would not be liked. For the moment, the leading Academic styles were largely discarded in favour of a style with principles not yet formulated and capabilities not fully tested, and, therefore, not easily learnt or taught. The want of a certain directness of aim under these circumstances must be noticeable, together with a certain lack of enthusiasm, compared with even ten years ago. It was to be hoped that the increasing attention that had properly been paid to sanitary matters was not to be given at the expense of design. During the past fifty or sixty years, English architecture had been going through a course of archaeological studies, taken, curiously enough, in something like their original progression, with that progression accelerated a hundredfold. Some amongst his unprofessional hearers might, perhaps, remember when the influence of Stuart and Revett was still felt, and Grecian was thought to be the only architecture. He might remember how, since his youth, he had been hurried on, from Greek to Roman, or a freer Classic style, through all the turmoil of the various stages of the great Gothic revival; then introduced to a glimpse of the dainty conceits of Queen Anne, and even Georgian, and now finally found himself somewhat bewildered and out of breath, as he wondered whether, having been led to this point, he was going to be carried on still further, and brought face to face with a real Victorian style, or, whether, having come to the brink, he would turn back and begin the long round again. This was a question which the young men of the profession would have to answer, and on their diligence, enthusiasm, and imagination that answer would depend. They had now revived all the styles, without succeeding in doing more than revive them. They had hardly revived them or advanced them much beyond the point at which they were left by the originators. Indeed, the Italians were the only people who had ever succeeded in doing this. From the way in which the various styles had been revived, and in turn discarded, we seemed drawn to the conclusion that they were each brought to the highest perfection possible before being abandoned by the old workers. We had now reached the further stage, when all the previous epochs of architecture had been tried, and in some sense found wanting, and now, if ever, a departure must be made. If the departure should occur, it would depend for its life as much on the intelligent interest and the support of the general public, as on the energy of the members of the profession. In all arts subsidiary to architecture there was an increasing interest, and architects might justly claim a share in the

initiation of this. Since, and commencing with the Gothic revival, great attention had been paid to furniture, decoration, needlework, and even ladies' dresses, all of which had been designed by architects. So great an improvement had been made in these, that architects were now, he trusted, able to give less time to such matters and more to architecture proper—the real building in brick and stone. There were now certain well-known æsthetic villages not far from town, where people lived in “cotts,” and filled their gardens with sunflowers, where ladies dressed to suit the houses, and where anything but red brick and white-barred windows were absolutely tabooed. We could not all live in “cotts” even if we wished to, nor all be surrounded with the quaintness of these villages these villages furnished, but the improved taste of the public might assist in checking the miles of dreary stuccoed dwellings with which our suburbs were being burdened. Year by year an overwhelming stretch of Portland cement and stucco was laid upon us thicker and thicker, and we could not remove them, though they fortunately show, in most cases, a great desire to speedily dissolve themselves. Surely it was the fault of the public themselves if this class of building was allowed to still further increase. Let the speculating builder be given to understand that it was to his interest to supply something of better character, and he would find means to do so. These æsthetic villages showed that houses might be built of honest materials, and yet pay, and that palatial monstrosities, badly planned, badly built, and badly drained, were not a necessary evil of the 19th century. Great efforts had been made in recent years to improve the dwellings of the labouring class, but they hardly required improvement more than the suburban dwellings of the middle classes. Our churches had now been nearly all restored. Let architects now set to work to restore something like design in our residential streets, and, more fortunate than church restoration, it would probably be a long time before a society would be started to oppose it. Architects were powerless in the matter unless backed by public opinion, because their aid was not sought in the erection of the houses he condemned. Architecture, to be a living art amongst us, upon which architects can work with the full sympathy of the public and each other, must not be reserved for display only in public buildings, but must also be found in our smaller houses, so that, beginning with the lowest end of the scale, we could work upwards. They looked to such gatherings as the one held that evening, as one of the means by which the general interest in the architectural art might be extended. When this was accomplished, and a knowledge of architecture more widely diffused, the result would be seen in the fact that, not only great buildings, but also the smaller dwellings, would be designed in beauty and built in truth.

Professor T. ROGER SMITH expressed a hope that the numerous attendance that evening was a promise that the session, which would be a more than ordinarily important one, would be one of continued success. For himself, he should endeavour, so far as it lay in his power, to enable the Association and University College to be of mutual benefit and assistance to each other. The exhibited prize-drawings appeared to indicate that the classes of the Association had produced some excellent work during the past session, creditable alike to the prize-holders and to the Association, although it was a matter of surprise and regret to him to see that a considerable proportion of the successful students were not present to receive the awards in person. Those who had seen something of professional life, knew that two of the Darwinian phrases were justified by daily experience: that there was a very real struggle for existence, and that there was as certainly a survival of the fittest. While there was thus in the drawings on the walls a bright augury of future success to the students who had taken prizes, they by no means represented all the good effected in these classes. The steady work accomplished by others, who might last year or next year have taken the prizes, but had now been distanced, would not be without its reward. Although for a time, the mere prize was aimed at, in truth the real honour lay beyond, and existed in the mental efforts called forth by the competition, and the preparation made for actual business-life in the future.

Mr. T. CHATFIELD CLARKE thought that no one who heard that address could fail to see that the young men now growing up had opportunities for education and self-improvement, such as never previously existed, and that it would be a deplorable thing if these opportunities were not availed of to the fullest extent. The search for a new style, as the President had intimated, was not promising; it was singular that, in an age marked by the general diffusion of knowledge, by the advance of scientific discovery, and its utilisation, the spirit and genius of original design seemed to make absolutely no progress. Some of the lack of enthusiasm, to which reference had been made, must be due to the fact that the profession had recently lost several of its foremost workers, including Sir Gilbert Scott and Mr. E. M. Barry, two of the most polished and clever professional men of the day, and the latter a good all-round man, with great powers, both of planning and design.

Professor KERR remarked that the Association occupied a high and very important position in the profession—a position which he declared to be absolutely unique in the world. In no other profession, in no other country, was it possible for the actual students to form and organise a society possessing such power and influence in the profession, which had developed and conducted systematic instruction with the greatest possible success, a success which had been continued for 35 years, and which bid fair to go on for at least another 350 years. The draughtsmanship of the prize-drawings on the walls around them was of the very highest quality; indeed, the amount of masterly skill and draughtsmanship, which was displayed by so many young men was amazing, and there was a danger that buildings would be, and, indeed, now were, mere reproductions of drawings, instead of the converse being as it should be the case. No more useful body than the Association existed, and he was, therefore, very glad to see this year so large an assembly, and so many fresh faces amongst those entering upon a cultivated, a gentlemanly, and what was more important in these days, an honest profession.

During the evening several male-voice part-songs and glees were given in the Institute-room by the Artists' R.V. Musical Society, conducted by Mr. W. H. Thomas, and in the lower galleries Messrs. Coote and Tinney's band played a selection of operatic music.

RHIND LECTURES IN ARCHEOLOGY.

MR. JOSEPH ANDERSON delivered the fourth of the present course of Rhind Lectures in Archaeology, at Edinburgh on Friday last, when he dealt with "The Brochs, or Dry-Built Round Towers of Scotland." Mr. Anderson first gave a description of the Broch of Mousa in Shetland, which consists of a solitary tower of circular form, wide and lofty, constructed of undressed stones, laid upon each other without mortar or other binding material, so that the great mass of its un-cemented wall coheres simply by its own vertical pressure. The tower is placed on a small promontory, and stands about 20ft. back from the edge of the rocks, which slope irregularly to the tide-mark about 20ft. below. There are slight remains of an entrenchment on the sides which look landward; those facing the sea are protected by the natural features of the ground. The suggestion of solidity and strength, which is due to the bulk of the building rather than to the character of its masonry, is further intensified by the absence of external openings, the whole exterior surface being unbroken by a single aperture except the doorway. The wall of the structure is 15ft. thick, inclosing a court 20ft. in diameter. The wall rises to a height of 45ft. Opening from the court is a series of chambers on the ground-floor, constructed in the thickness of the wall, and rudely vaulted with overlapping masonry. Above these are successive ranges of level galleries, also in the thickness of the wall, each going round the tower, and placed so that the roof of the one below always forms the floor of the next above. These galleries are crossed successively by a stair, from which access to them is obtained by facing round and stepping off downwards across the vacant space forming the well of the stair. The three lower galleries only are lighted, and the windows are placed in vertical ranges, so close to each other as to be separated only by

their upper and lower lintels. These remarkable features, he showed, were not related to those of any variety of castle of historic times, but there were many similar structures in different parts of Scotland, among which he instanced and described the brochs at Glenelg, and that at Loch Duich. It was evident, he remarked, from an examination of these structures, that they all pointed more or less obviously to the presence of a double intention in the minds of the constructors of the brochs. The design of the whole structure, and the arrangements of all its separate parts, exhibited a careful and laborious adaptation of the means and material to the two main objects of defence and shelter. The clever constructive idea of turning the house outside in, as it were, placing its rooms within its walls, and turning all their windows towards the interior of the edifice, implied boldness of conception and fertility of resource. The door, securely fastened by its great bar, was too strong to be carried by a rush. Placed 4ft. or more within the passage, it could only be reached by two men at a time, and the narrowness of the passage prevented the use of long levers. But even if forced, and entrance gained to the interior court, the enemy would find himself, as it were, in the bottom of a well 30 to 40ft. in diameter, with walls 50ft. high, pierced on all sides by vertical ranges of windows, or loopholes, commanding every foot of the space below, and rising to the number of 20 or more immediately over the door which gives access to the galleries. In short, the concentration of effort towards this double object was never more strikingly exhibited than in these structures, rude though they were in construction. As regards the range or area of the brochs presenting these typical features, he referred to those on Cockburnlaw, in Berwickshire; at Torwood, Stirlingshire; and Coldoch, Perthshire; which were all the examples known on the mainland of Scotland south of the Caledonian valley. A few years ago they were grass-covered hillocks, indistinguishable from many others that are yet to be seen in various quarters of the same wide district of country. It was impossible to say how many of these unexamined mounds—which exist abundantly in the valleys of the Forth and Teith for instance—might be of similar character. But it was possible to say that where three have been found without being specially looked for, the probability was that more would be found when they were looked for. The case was far otherwise, however, with reference to the district of country that lies to the north of the Caledonian valley and the isles around the northern and western coasts. In such remote and frequently rugged and barren localities the remorseless activity of the agricultural improver had made but little progress in the removal of the ancient land-marks, and brochs and sepulchral cairns, stone circles, and standing monoliths, were still comparatively abundant, though every season was diminishing their number. Still, he estimated that as many as 300 brochs exist in the five northern counties. That meant that we had here the remains of a period of architectural activity which had no parallel in the early history of our country. Indeed, he questioned whether all the remains of the feudal period in Scotland, from the 12th century to the Reformation, would be found to equal in magnitude the extent of constructive architecture thus represented. Out of Scotland this type of building was totally unknown. In his last course of lectures, he showed that, as a nation, we were the sole possessors of the remains of a school of art exemplified in a series of monumental types which were so truly unique that no other nation possesses a single example. He had now demonstrated that we were also the sole possessors of the remains of a school of architecture which was as truly unique, which was even more pronounced in its features of absolute individuality, and of which no other nation possesses a single example. This was a fact in the general history of architecture which would not be found noticed in architectural books. The presence of this vast series of massive structures, so closely alike in their general features, implied a wide-spread concentration of thought and energy towards a common object which was found only in communities that have attained to a comparatively high condition of general culture and social organisation. Judged by their proper standard—the measure of their fitness for the purpose for

which they were plainly intended—they fulfilled the most exacting requirements of criticism. In order more fully to determine the nature of that purpose, the lecturer went on to describe brochs found in Orkney and Caithness which present other peculiar features, such as defensive works, wells, and drains, and even a water supply within their own inclosed area. The round towers of Ireland originated in the liability of the ecclesiastical communities to sudden danger of plunder and murder by roving bands of marauding Norsemen; and it was certainly a suggestive fact that in Scotland the area which was chiefly occupied by the brochs was an area which was peculiarly exposed to similar occurrences, over which there ebbed and flowed for centuries an irregular intermittent warfare, chiefly consisting of plundering forays by bands of marauding invaders. Against such danger to the persons of the people and the produce of their soil there could be no more effective system of defence provided than a multitude of "safes," which should be burglar-proof and big enough to contain the families, goods, and cattle of the joint proprietors; and that this was the idea of which the typical broch structure was the actual embodiment appeared to be fairly demonstrated from the character of its construction.

The fifth lecture was delivered on Monday, the subject being "The Brochs and their Contents." The lecturer observed in the outset that in 1852 the late Mr. A. H. Rhind, of Liberton, the founder of the Rhind Lectureship, made a systematic investigation of an ancient structure at Kettleburn, near Wick, in Caithness. It was a work of great magnitude, employing a number of men for upwards of three months. It was easy for them, with their superior knowledge of that class of buildings, to recognise the features of the structure as those of a broch, although it was not so considered by Mr. Rhind. The external appearance of the ruin was that of a mound somewhat more than 120ft. in diameter, and 10ft. high. It stood in a cultivated field; the plough had regularly passed over it for a quarter of a century, and a cottage had been built out of one of its sides. Though thus diminished and dilapidated, there remained enough of its structure underneath its surface to show clearly what were its general features. Where fully cleared from the ruin of its upper portion the lower part of the building showed a circular construction, consisting of a wall 15ft. thick surrounding a central area of 30ft. diameter. The doorway, passing straight through the wall, was flanked by a guard-chamber on either side. Remains of two oblong chambers, constructed in the thickness of the wall, were also found some distance apart. The roofs of all the chambers were gone; but the lintels remained on the passages leading into them. There was a well with steps leading down to it in the central area. It was 9ft. deep, and, being covered for the support of a partition wall which passed over it, was full of good spring-water when discovered. The area inclosed within the circular wall of the broch was subdivided into irregular shaped spaces by walls built across it in various directions, and abutting on the main wall. The area outside the tower, for a distance of 25ft. from its external wall, was covered by the ruins of similar irregular constructions. The whole was surrounded at that distance from the central tower by a wall 3ft. thick, of whose height little more than the foundations remained. After describing the objects, manufactured and unmanufactured, of bronze, iron, stone, and bone, found within the broch, the lecturer said that, so far as the evidence went, there was no reason for attributing to the people who had inhabited the broch an exceptionally low condition of culture or civilisation. They had seen that the type of defensive dwelling with which they found those people associated was one which possessed remarkable features of constructive merit and originality of design. Their diet was not less varied in kind and quality of nutriment than that of modern times; they possessed iron and bronze; and their manufactured implements showed that they were neither destitute of technical skill nor deficient in artistic taste. He proceeded next to give an account of the broch of Kintradwell, some miles north of Brora, excavated by the Rev. Dr. Joass. It was situated on a natural terrace close to the edge of the declivity which marked the old sea margin of the east coast of Sutherlandshire,

Previous to its excavation it was a rounded grass-covered knoll. Within this mound, formed by the debris of the structure, the basement of the broch was found entire to the height of about 14ft. The circular wall, 18ft. in thickness, inclosed a central space 31ft. in diameter. The doorway was 7ft. high, with inclined instead of perpendicular sides, so that the width was 3½ft. at the bottom and 3ft. at the top. The entrance passage went straight through the wall, and was provided with cheeks for two doors—the first at 6ft. within the outer face of the wall, and the second 8ft. farther in. Between the two doors a guard chamber opened on the right of the passage. It was circular in form on the ground plan, 7ft. in diameter and 11ft. high, being roofed in the usual way by overlapping stones. On one side of the area was a well 7ft. deep, with steps leading down to a point 3ft. from the bottom. A stone cup, presumably the common drinking-cup of the establishment, lay near the steps of the well. Having pointed out some constructive features in which this broch differed from others already described, he said a little to the north-west of the principal group of outbuildings was a shallow open cavity lined with flat stones set on edge, and containing the fragments of a human skeleton and an iron dagger blade. In one of the outbuildings also there were found a human skeleton and an iron spear head. Portions of eight other human skeletons were found in and about the ruins, mostly at a depth of from 2 to 2½ft. under the turf which covered the mound, but not in such circumstances as would necessarily imply that they belonged to the period of the occupation of the broch. It was rather suggested, by the frequency with which such remains had been met with in other cases, that burials were occasionally made in these mounds long after they had become grass-grown hillocks. The relics in this mound also included a variety of manufactured articles in stone and bone, bronze and iron, the stone objects forming a very considerable and striking group, and including upwards of fifty querns or hand-mill stones. Having next given an account of another broch in Dunrobin Park, also excavated by the Rev. Dr. Joass, he said the most interesting objects in metal found in it were two plates of brass, each a little more than 1in. in thickness—the one oblong, rectangular, 11in. in length and 7½in. in breadth; the other nearly semi-circular, and about 7½in. in radius. Both were found near the floor of the interior area of the broch. They were hammer-marked with blows of the pin end of the hammer in lines across the surface. That they were brass and not bronze was certified by the analysis made of the one now in the museum by Dr. Stevenson Macadam. The composition was found to be 82 parts of copper to 16 of zinc, with one part of tin and a trace of lead. This fact was important, because while the alloy of copper and tin which constituted bronze had been in use for an indefinitely remote prehistoric period, the alloy of copper and zinc which constituted brass was not found earlier than the period of the Roman Empire. Mr. Anderson next gave an account of the broch of Yerros, which he had excavated in 1866 and 1867, and which was situated in the south-east of the loch of the same name, about five miles south of Wick; and of the brochs of Old Stirkoke, Bowermaddon, and Dunbeath. These examples, he said, sufficed to convey a general idea of the nature and contents of the brochs of Sutherland and Caithness, and to show how closely they resembled one another, alike in the style of their construction, the nature of their arrangements, and the general character of their contained relics. He then proceeded to notice briefly a few of those which had been excavated in Orkney and Shetland, and which all exhibited the same typical structure. That the people, he observed in conclusion, who occupied these extraordinary strongholds, were the people of the soil, and not strangers effecting a settlement, was plain from the general character of the relics of their domestic life. The typical forms and relations of these relics were those of the Celtic era and of post-Roman times. No group of objects in its general *façade* entirely comparable to the group which was characteristic of the brochs existed either on the continent of Europe or anywhere out of Scotland, but the typical forms of which the group was composed had special relations with those which characterised the general group of relics assignable to the early Celtic or Iron-age culture

of Scotland, England, and Ireland. This unique series of objects formed a unique type of structure, illustrating a phase in the early culture and civilisation of our country which but a few years ago was absolutely unknown, and was now only beginning to be disclosed. This unique series already formed a body of scientific material of exceptional interest and suggestiveness, if the National Museum could afford the space necessary to allow it to tell its own story in the most effective way. And as these lectures had continuously disclosed series after series of similarly unique groups, it was obvious that if they also could be made to speak to the public eye the lesson thus taught would be plainly this—that Scotland had an archaeology which could only be disclosed by her own remains.

ART EPOCHS.

PROFESSOR BROWN commenced the work of the Fine Art Class of the University of Edinburgh, on Tuesday, with an introductory lecture. At the outset Professor Brown said: I cannot address you to-day without a word of deep regret for the loss which all who are in any way connected with art in Scotland have sustained by the death of the distinguished artist who has so lately passed from amongst us. The loss of Mr. William Brodie is both a public and a personal one. Of the public loss those will speak with whom in his busy life he was brought into official connection; but no one who ever saw him engaged on his public duties will fail to know what a secretary the Academy has lost in him, and what a wise adviser has left his place vacant at its council board. Nor will his place in art be easily filled. He had a rare gift in portraiture, and held a position second to none in these islands in a branch of art in which some of the greatest artists of the world have won their triumphs. His monumental works, which were neither few nor unimportant, showed that modern sculpture has no need to turn to genre in search of a field for its efforts; but he will be remembered, perhaps, by the largest number of his admirers for his especially national gift in realising in his marble statuettes the pathos and the humour of some of the finest creations of Sir Walter Scott. All whose privilege it was to know Mr. Brodie in private life will miss in him the kindest of friends and the most prudent of counsellors. To myself personally the loss is peculiarly heavy. I can never fully express the gratitude I feel for his reception of me when I came as a stranger to Edinburgh, or my sense of what I have been deprived of now that his helping hand can be no more stretched out to me. When I took leave of him last spring, I looked forward for many years to the enjoyment of his genial friendship and the assistance of his advice—advice made of especial value by his shrewd mother-wit, his large experience, and, more than all, his earnest and noble character. But the ill-health from which he was then suffering changed rapidly to mortal disease, and my only connection with him now is to add my word of respect and affection to the many which will be spoken about his grave, my tribute to the memory of one who united in a happy way, peculiarly his own, the double qualities of a good and gifted man.

Proceeding with his lecture, Professor Brown said that among the distinct epochs of artistic activity of which the historian of art had to give an account, there were two which were distinguished above the rest by the number and excellence of the works produced in them. These were the epochs of Classical art and of that Mediæval and Christian art, which, though it flourished on both sides of the Alps, found its most perfect development among the Italian cities in the thirteenth and following centuries. The special character of these two art epochs was imparted to them mainly through the close relation which existed between the activity of the artist and the general life of the community in which he worked. For art was in these times, as it were, the natural speech of the community, and everything which was of interest to it was recorded in some way or another in an artistic form. Hence a general demand for works of art in every variety of shape and for every purpose of public and private life—a demand which led to their production in an abundance of which, in the case of Greece at least, it was difficult to form any adequate idea. Hence, too, the creation of a body of artistic craftsmen more

numerous and skilful than had ever at other periods been consecrated to the service of the arts, craftsmen handing down their skill from generation to generation, till the technical excellence of their work reached a point unattainable by modern imitators. But not only in technical excellence, but to a still greater extent in the higher artistic qualities, the art of these two epochs owed its acknowledged pre-eminence to its close connection with the national life. Going on to compare the art of Greek and Mediæval times with that of some other epochs, in order to see more clearly wherein its special characteristics consisted, the lecturer said that with us art belonged rather to the few, and pretended to no close connection with the interests of the people. It did not follow from this, however, that art was necessarily of less importance in the present day. On the contrary, the inartistic character of most of our modern surroundings might make art all the more valuable an element in our lives; but it did follow that art imported, as it were, deliberately from without into the circle of our interests, no longer possessed that naïve simplicity which was the peculiar charm of the early productions of Greece and Italy. There, where the whole community participated in the activity of the arts, art came so naturally to the people that they would never be called upon to give any special thought to it. It was mixed up so closely with daily life that occasion never arose for reflection or discussion upon it. Anything like theorising upon art, or even art criticism, was unknown in the palmy days of Greece and Italy, and a philosophy of art was an invention of quite a recent era. Hence it followed that the ancient artist worked in an entirely different artistic atmosphere to that which surrounded the modern—one much less charged with reflection upon art, and so in proportion more favourable to artistic production. For though, on the one hand, the artist of more simple times was not of so much importance as a personage as he was in the modern world, he had the advantage of being able to work in perfect freedom, unwatched and uncriticised. Having pointed out that, as a condition of securing this quiet and freedom for his work, the ancient was content to sink his own personality as creative artist in that of craftsman, Professor Brown went on to remark that a popular modern artist might well afford to forego a portion of his personal display for the sake of working under the same conditions as the Greek. The artist himself was, indeed, so far as the artistic gift was concerned, the same in every age, but there were times when he lacked the stimulus which at other epochs called forth his noblest powers. Such a time was the present. Though the artist of to-day might invest his poetic creation, his scene of rustic character, or his landscape, with as true an artistic charm and as pure a grace of line or colour as any Greek sculptor, his youth or maiden, or Mediæval frescoist his Madonna, yet his efforts were circumscribed by the absence of those great demands to which Athenian and Florentine were so ready to respond. Through the limited number of works of a public character, which in this country at least gave employment to the artist, he was deprived of the most valuable of all means of education and of the highest stimulus to his powers. The place of this stimulus they often saw supplied in a somewhat feeble form by criticism. Critics sometimes told the modern artist that his forms lacked power, his style grandeur, the effect of his whole work simplicity. And the critics might be right, and yet the fault might not lie wholly with the artist. There was many an artist of to-day who could cry with the Italian frescoist of old, that, now that he had learned the manner of his craft, he would fain cover the whole circuit of his city walls with stories, but no great work ever came in prospect to quicken the generous fire of his genius. After next briefly comparing the art of Greek and Mediæval times with that of Egypt and Assyria, the lecturer pointed out that the former occupied a place in history midway between the art which in Egypt and Assyria was purely ceremonial, without any life or independence of its own, and that which in modern times was purely secular, and produced for the satisfaction of private taste. On the one side, as based upon religion, as consecrated to the service of the State, it was charged with meaning, and appealed not only to the artistic judgment, but to the heart and conscience of the citizens; on the other side, as the work of men born and bred

in the midst of shapes of beauty, and themselves modelling and painting as naturally as if there were nothing else in life to do, it possessed in all its forms that purely artistic charm, that grace of spontaneity and naturalness which was the unmistakable stamp of the born artist. The lecturer concluded with some remarks on the study of the remains of ancient art.

DR. ZERFFI ON PREHISTORIC ART.

ON Wednesday, at the Crystal Palace, Dr. G. G. Zerffi, F.R.Hist.S. and F.R.S.L., delivered the first of two courses of 12 lectures each on "The History of the Art Development of Humanity." The lecture was a general introduction to the subject, and the immediate topic was "Prehistoric Art." The lecturer started by saying that he should treat the subject scientifically, meaning by the latter term anything capable of being defined analytically or technically. The first part of the lecture was devoted to the explanation of certain diagrams of the frontal angle in the human face. The facial angle of the black races was about 83, of the yellow 85, and of the white 92. It was the brain faculty they had to work upon, and with a small brain it was impossible to get a true work of art. The savage race might produce beautiful things, but none of them were true works of art. The black man might imitate, but never originate. The yellow races had attained a higher development, but were now stationary; the patterns of the Chinese and Japanese were the same as those of 3,000 years ago. The white races, on the contrary, were progressive. There was, in fact, no limit to the degree in which the white brain might be cultivated, though that limit, as regards the black race, was very marked indeed. Taking humanity altogether there was real progress. The earlier inhabitants of the earth had developed into families, tribes, and nations; each might be traced to the three different facial angles. The lecturer then described the habitations of prehistoric man. The black race, those with a receding facial angle, could not go beyond a mere tripod of three sticks, with a skin or grass covering, and an entrance always low. The yellow or square-headed man made a square house, with curtains, and to keep off snow and rain learned to place a conical roof on it. The white man brought his reasoning power to bear upon the problem, and made his house with square walls, conical roof, and, in addition, windows for light and a proper door for admission. Further on still, man became conscious of his beauty, and tried to ornament himself, first by tattooing his body, and then by arraying himself in such gorgeous apparel as he could get hold of. The clothes of barbaric races were nothing but the substitute for the tattooing in which New Zealanders and others indulged. The bright garments of the Eastern nations and of Hungarians and Poles were only the modern survival of the same idea. As for the art of prehistoric man, its earliest instance was found in the incised representation of a mammoth on an ivory blade, a picture of which was shown in the room, and the artist of which, the lecturer said, might well claim to be a prehistoric Michael Angelo. A striking account was then given of the Cave of Aurignac, in France, where had been discovered in close juxtaposition the bones of antediluvian animals, and weapons and utensils, which proved that prehistoric man not only killed his prey, but cooked his food. A necklace of stones was shown, the symmetry of which would not disgrace a modern jeweller. The lecturer next remarked upon the great similarity between the huts of the Laplander and the ancient tombs; and remarked that this was owing to the idea of a future state possessed by these people, the dead being regarded as still living, though in another sphere. In the course of a description of Stonehenge, he remarked that it was undoubtedly an astronomical temple, an observation which elicited the assent of many in the company. In an eloquent peroration the lecturer concluded by asserting that the progress of art was the history of the progress of the human race. A spoon was as good plain as ornamented, a rude rudder would steer a ship as well as a carved one, yet both were ornamented. Beauty and virtue were in truth the same. Beauty was virtue in form; virtue was beauty in action. It

was from such a standpoint that men would lose their little petty animosities, and without this no genuine estimate could be formed of the progress of the race.

NEW BOOKS ON ARCHITECTURE AND CONSTRUCTION.

WORKS on the theory of art and architecture are not very popular in this country, and it is not often we have to review a work of nearly 500 pages devoted solely to metaphysical disquisitions. Mr. Leopold Eidlitz, architect, in a new work on "The Nature and Function of Art, more especially of Architecture,"* attempts to inquire into the causes of the present condition of architecture, and to define the nature and function of art in general, and of architecture in particular, with the object of showing how architecture may become again a living and creative art. Mr. Eidlitz is not the first who has pointed out that architecture is a dead language, that the architect's education is too much confined to historic eras, and runs on the forms of the past. Years ago these views were advanced in these pages on somewhat the same grounds. No one can dispute the illogical consequence of accepting the completed forms of art as its basis, in other words, of taking styles as the groundwork of art. Few architects can venture to deny also the assertion that architecture has ceased to be a living art. It would be vain to attempt to give the reader any idea of the arguments the author here unfolds. It is sufficient to quote a few sentences. The author says: "That art deals with ideas is universally admitted; but it seems desirable to know exactly how the idea is finally expressed in matter, how it assumes a physical form. The exact definition of this process may lead to a better understanding of the nature of beauty, and also of the nature and function of art." Again: "If architecture is to be a living and creative art, the study of styles must be directed to the art principles manifested in the relation of their forms to contemporary ideas and knowledge of construction, to the end that new forms, based upon modern ideas and the present development of construction, may supersede the forms of the past." We pass over several of the earlier chapters on common sense and taste, the aim of architecture, definition of architecture, views on proportion, &c., which contain many sensible ideas, but which are painfully verbose, to other chapters touching on more practical views of the subject. The chapter on definition of architecture is not lacking in philosophical reasoning, but the author leads the reader into a maze of useless analogies to show how an idea can be expressed in a structure. It is a kind of Will-o'-the-Wisp hunt, and the whole 16 pages might have been condensed into a couple. Another unnecessarily long chapter on "Ideas" follows, which seems to enter into a variety of speculations, but from which the reader can draw few practical suggestions. Monuments form the subject of another chapter. "Every expression of thought in durable form is a monument," and the gist of the author's reasoning is apparently to show that the art of designing a monument is to give the structure a form which will correspond with the acts performed within its walls, and the human groups accommodated. The monumental form should be dictated by mechanical and other laws in the same manner as a natural organism is developed by certain environments. Discussing form and construction, the author begins by asserting the fundamental value of statical mechanics. Methods of construction are defined to be geometrical demonstrations in matter of mechanical ideas, and are for that reason not works of fine art. Fine art means representation, and not demonstration. The author of a demonstration of an idea is not an artist. The author very justly observes that many architects design the outer form of their buildings as if it had no relation to the interior. Sham construction is preferred to the real. Mr. Fergusson is quoted on this subject, and the author's elaborate argument may be summed up in the simple proposition that form should be controlled by statical laws in regard to the material, and that, in short, iron columns ought not to be

imitations of stone and wood. We have not space nor inclination to follow the author into the subject of proportion. The remarks are in the main sound generalisations which few would care to question. The practice of lining brickwork in Northern Italian buildings is reprobated, and in the main we agree with the view that portions of the brickwork should find expression, and not be totally concealed by marble slabs. Terra-cotta is briefly referred to, and the author condemns the employment of iron when used to imitate stone or marble. We do not enter into the other chapters dealing with style, ornament, and colour decoration, analysis, criticism, &c.; our only object has been to show the general drift of the author's speculations.

"The Science of Building"† is the title of a treatise which has been well received by students of the profession. Mr. E. Wyndham Tarn, M.A., architect, is the author of the book, the second edition of which lies on our table. We noticed the appearance of this useful guide at the time of its publication, and we need now merely refer to the enlargement it has undergone. The preface informs us the whole of the work has undergone a thorough revision, and that much has been rewritten, while a considerable amount of new matter has been added. Amongst the additions that have been made we find, the practical application of that useful proposition, the triangle of forces, to the bracket, a piece of construction which has not been so generally referred to in these textbooks as its importance demands. In the section on "Stability of structures" the author refers to "corbelling out" walls, and shows the danger of allowing builders to make chimney breasts extend a considerable length of the wall when corbelled out above a certain height. A new chapter explains the geometrical means of determining the thrust of an arch, which may be usefully employed as an approximate method. A similar method was described in the *BUILDING NEWS*. Gothic vaults, cupolas, and some remarks on the construction of spires are usefully introduced, showing the conditions of the stability of these structures, their thrust, &c. The chapter on the chemical composition of stones has been enlarged; and the author has added some useful facts bearing on the nature of iron and the mode of finding the safe load on a beam. We find also a new chapter upon the method of protecting buildings from lightning, and several useful tables, which will make this new edition a valuable handbook to the student who is desirous of qualifying himself for the architectural examinations. As a repertoire of the scientific principles of construction in which the architect is concerned, Mr. Tarn's little book is unsurpassed. The same author's work on "Practical Geometry,"‡ intended for the architect, engineer, and surveyor's use, has also reached a second edition. We find few changes in the work with the exception of appendices, treating on diagrams of strains, as a practical application of geometry to constructive purposes, and on isometrical projection. As one of the best textbooks on "Practical Geometry," applicable to the architect's wants, we can again highly recommend it to the student.

"Tramways, their Construction and Working,"§ is a new edition, or rather a supplementary volume, by Mr. D. Kinnear Clark, M.Inst.C.E., of a work we have already noticed. The author's original work was a very useful treatise on the subject of tramway construction, and the present volume is the result of experience during the last four years. We must here content ourselves with a very general glance at the new work. Mr. Clark continues his account of expenditure by referring to the North Metropolitan Tramway Company, which, he says, follows the best model for the yearly or half-yearly statements of accounts, on the system prescribed by the Regulation of Railways Act, 1868. Some very instructive tables are furnished, giving the total length of streets and roads traversed by tramways in the United Kingdom, the capital, expenditure, and the rate per mile. The cost, receipts, expenses, and working stock of tramways for the last few years form another useful table, of much prac-

* The Science of Building. By E. WYNDHAM TARN, M.A. London: Crosby Lockwood and Co.

† Practical Geometry. By E. WYNDHAM TARN, M.A. London: Crosby Lockwood and Co.

* The Nature and Function of Art, more especially of Architecture. By LEOPOLD EIDLITZ, architect. London: Sampson Low, Marston, Searle, and Rivington.

tical interest to promoters and others. The chronological summary of tramways is a capital index of progress made, and the various systems of construction known as Kincaid's, Wilson's, the Aldred-Spielmann system, Trusswell's, Vignoles', Deacon's, Shaw's, and others, are fully described and illustrated, with sections and details. Speaking of horse-power, Mr. Clark says: "That horse-power will eventually be superseded by mechanical power is a foregone conclusion." The direct steam-power tramway-engine is pronounced more economical than the compressed-air system. The work contains detailed particulars, with engravings, of all the principal steam cars and locomotives, including France's hot water and Beaumont's compressed-air locomotives; and we can fully accord to Mr. Clark's new volume the merit of digesting in a practical manner the results of the last few years' experience in this important branch of engineering.

HENDERSON'S ARCHITECTS' AND ENGINEERS' SCALE.

MR. ANKETELL M. HENDERSON, C.E., of the firm of Henderson and Smart, architects, Melbourne, Victoria, has invented a new scale, the object of which is to secure rapidity and accuracy in drawing. At a recent meeting of the Royal Society of Victoria, the scale was described by the inventor, as designed to meet the needs of the architect more than those of the engineer. The scale has been used in the office of the inventor for some time, and its good points tested and developed. To understand Mr. Henderson's new scale fully, a diagram of its application is necessary; we may, however, describe it in general terms from the description and engravings he has sent us. With ordinary scales, the setting out of a dimension consists in placing the zero of the scale opposite the starting-point, and a pencil or pricker is used to mark off the required distance. This operation requires the eye to be perpendicularly over the zero, and the head and eye have to be moved to mark off. Mr. Henderson's scale obviates this operation and the chances of error. It consists of a steel point fixed to the edge of scale at the zero and the end of scale. By simply moving the scale till the required distance is opposite the starting-point, and raising the back of the scale, the steel point marks the distance on the paper and all movements of the eye and head is avoided. From the diagrams we have before us, we find important differences in the division of the scale. In the usual architect's scale the zeros are at each end; in this instrument they are placed 10 feet from the ends, by which means rapid working from centre lines is facilitated—a decided advantage in preparing scaled drawings. The upper side of the scale shows the centre portion divided into 40, and the under side into 60 parts. The author, in speaking of the use of the scale, refers to the value of setting out joists, rafters, studs, &c., to the proper centres. This operation can be performed by a scale on the back. Each of the larger dimensions on the scale is 16in., and the smaller 8in. It is often necessary in drawings to lay down series of odd and fractional dimensions, such as stair-treads 11in., 10½in., 9¾in., &c.; courses of brick, 4 courses to 13½in., or 13in.; patterns of tiles running 6½in., 9¾in., &c.; centres of palisading 3½in., 5in., &c. Such divisional work is performed by an arrangement called a "reducing arc" on each side of the instrument, by which means, dimensions from 12in. to 5in., running 1-16in., may be set off on the front of the scale, and from 8in. to 5in., in 1-16in., on the back. "This is done by setting the scale so that the zero point and the required dimension are on the line to be divided, and then marking off with a pencil from the scale, or still more rapidly, by drawing a line along the scale on the paper, and using the toothed ends for registering the divisions"; calculations are avoided, and time saved. The scale also shows the number of risers of any fractional number, such as 6½in., necessary to go from one floor to the next, and the number of treads of any width can be rapidly found. On the upper side of scale is a diagram of radiating lines, by which the widths and gutters falling 1½in. in 10ft., and on slopes of 20°, 30°, 40°, &c., may be instantly obtained opposite the respective lengths of gutters; and another useful feature of the scale under notice is that stock dimen-

sions, those constantly occurring in practice and plan drawing, are given on one edge. Thus fireplace openings, 3ft.; doorways, 3ft. 3in.; fireplace jambs, 13½in., 18in., and 22½in., their projections and the width of hearth-stones being also indicated. Who has not wished the sizes of door-panels marked off, so that they may be rapidly drawn, the heights of bottom, lock, and top rails? These are shown on one edge of the scale. The sizes of flues required in setting out chimney stacks, instead of laborious sums of addition, are marked, and the dimensions are so arranged that the positions of fireplaces, &c., can be ticked off in their central positions. On the whole, from a careful study of the scale shown, we have every confidence in recommending it to the notice of the architectural and engineering professions. The architect and draughtsman, from the very nature of their work, require facility and expedition in laying off constantly recurring dimensions, and those who prepare plans and sections will find Mr. Henderson's instrument a great help in lessening the amount of purely mechanical labour involved in work of this kind. Accuracy also in the setting out of series of divisions, such as joists, stair risers, &c., is essential, sometimes of incalculable moment to the quantity surveyor, who also will find the scale an acquisition.

LIME AS A PRESERVATIVE.

LIME, it is well known, preserves ironwork; and Wren, in his "Parentalia," mentions the freshness of iron cramps which had been bedded in mortar for 400 years. It is usual to limewash iron mains, tanks, and other articles to prevent rust; and bricklayers are in the habit of smearing their trowels with mortar. In the demolition of old buildings the ends of joists, ceiling-laths, quarters, plates, and bond timber which have been bedded in lime-mortar, are usually found in a sound condition, in spite of their having been bedded all round. Higgins, in his well-known treatise on "Calcareous Cements," now rather an antiquated work, speaks of the value of lime-water or water freed from "acidulous gas." Something of this protection is rendered to wood and iron which are covered with lime. It is well known that an alkaline solution prevents corrosion of iron; and Mallet, in his work on "The Action of Air and Water upon Iron," proposed limewater to replace bilgewater, and thus prevent the internal corrosion in iron ships. Lime has a powerful affinity for oxygen, and to this cause may be attributed its preservative effects upon iron and other materials.

It would be interesting to record the many evidences of the value of lime in arresting decay. As long ago as 1769 a Mr. Jackson, a chemist, obtained permission to prepare timber for the shipyards, by immersing it in a solution of salt water, lime, muriate of soda, &c.; another practical experimentalist suggested slaked lime, thinned with a solution of glue, for mopping the timbers of a ship. The preservation of timber has been attempted by surrounding it with pounded lime, and several attempts have been made to preserve timber by the use of lime. Mr. Britton, in his work on "Dry Rot," mentions a number of cases where lime has been of service. He says "quicklime with damp has been found to accelerate putrefaction in consequence of its extracting carbon; but when dry and in such large quantities as to absorb all moisture from the wood, the wood is preserved and the sap hardened." "Vessels long in the lime trade have afforded proof of this fact, also examples in plastering laths which are generally found sound where they have been dry." The joists and sleepers of basement floors are rendered less subject to decay by a coating of limewash; and this might be renewed at intervals. The same writer adds, "it does not appear practicable to use limewater to any extent for preserving timber, because water holds in solution only about 1-500th part of lime, which quantity would be too inconsiderable, it, however, renders timber more durable, but at the same time very hard and difficult to be worked." These facts are instructive, they show, at least, that lime in a sufficient quantity kept dry is a valuable preservative agent, and some practical chemist might earn a deserved repute if he could prepare a lime solution that would be capable of rendering so substantial a service to all builders. Such a solution would be at

least sufficiently remunerative to make it worth while to try a few experiments in this direction. It is stated on good authority that the white ant in India costs the Government £100,000 a year for repairing woodwork, bridges, &c., caused by its depredations. Concrete basements have been found to resist the encroachments of the ant. Dr. Darwin proposed a process of timber preservation some years ago, in which an absorption of limewater was effected, and after that had dried, a weak solution of sulphuric acid, so as to form sulphate of lime in the pores of the wood. The growth of dry-rot or fungus on timber has been prevented by limewater, and many instances have been mentioned of its value.

The cleansing and sanitary virtues of lime are more generally known. The painter uses limewater to kill the grease upon his work instead of turpentine; and soot stains on the outside of flues have been removed by the agency of thick warm limewash. The value of lime white as a wash for walls, as a purifier of the air in sheds, stables, and other buildings, is unquestionable, though all limewashed roof-timbers have rather a rough and penurious look. As a preservative coating to the joists of floors and other timbers not exposed to damp, it seems worthy of a more extended trial.

INSTITUTION OF CIVIL ENGINEERS.

THE council of this institution have just issued the annual list of subjects on which they invite original communications. To those papers which shall be approved premiums arising out of special funds, bequeathed for the purpose, will be awarded. These comprise the Telford Fund, now producing £260 annually; the Manby Donation, about £10; the Miller Fund (for students), £160, out of which is established a scholarship of £40 per annum, tenable for three years; the Howard Bequest, about £16, which is accumulated for five years, a prize being then awarded to "the author of a treatise on the uses and properties of iron, or to the inventor of some new and valuable process relating thereto." The next award will be made in 1882. Amongst the proposed subjects are:—"The Adoption of a Standard Test-piece for Bars and Plates;" "The Mechanical and other Properties of Iron and Steel;" "The Behaviour of Iron and Steel under ordinary Loads, and up to the Limit of Elasticity;" "The Methods of Protecting Metal-work exposed to Corrosion;" "Modern Bridge-building in Germany;" "The Action of High Winds on Lofty and Exposed Structures;" "Determining the Discharge of Rivers;" "River Improvement;" "River Conservancy;" "Mechanical Power on Tramways;" "The Quantity of Water yielded by the Chalk Formation;" "The Analysis of Water for Potable Purposes;" "The Design and Construction of Covered Service-Reservoirs for Town Water-Supply;" "The Sewering of Towns on the Separate System;" "Drilling and Riveting Machinery for Girder Work;" "The different systems of Lifts in use in Warehouses and in Dwellings;" "The Distribution of Heat over large areas from a central source of supply;" "On proportioning Mains for the distribution of Water and of Gas."

THE ARCHITECTURAL ASSOCIATION "BROWN-BOOK."

THE annual report of the Architectural Association by the committee, just published in the "Brown Book," is a record of continued prosperity. The library is largely used and now contains, with recent additions, 1,100 volumes; the Institute library has been opened to members of the association under the age of 23 years. The entrance fee to the association has, by a new rule, been raised to one guinea. Admission to the associateship of the Institute being now attainable only by passing an examination, the arrangements of the classes have been varied with a view to making them specially useful to members preparing for that examination. The meetings of the classes generally have been rearranged; an entirely new class for the study of professional practice has been started; and courses of lectures, dealing especially with design and construction, and connected with the classes, have been arranged to be given by Messrs. E. J. Tarver and T. Blashill. The

appeal made by Mr. E. C. Lee, as president, to raise a fund for endowing a travelling studentship, resulted in the collection of nearly £700. The money will be invested in the names of Messrs. Cole A. Adams, E. C. Lee, and Aston Webb, as trustees, and the studentship will be of the value of £20, with additional prizes. During the past year the following honours were taken by members of the Association: Royal Institute of British Architects—Soane Medallion, R. T. Conder, and hon. mention in same competition, Mr. J. Lansdell; Tite Prize—R. W. Collier; Grissell Prize, 2nd—J. H. Curry and A. B. Pite, aeq.; Royal Academy—Travelling Studentship, W. J. N. Millard; Measured Drawings—Silver Medals, E. J. M. Allen and E. G. Hardy. The balance-sheet for session 1880-81, also published in this book, shows totals on the debit side of £196 11s. 10d. for the past, and £168 10s. 6d. for the current session, the principal items being members' subscriptions, £125 for past and £291 17s. 6d. current; entrance fees, £61 19s.; rent of offices, £18 17s. past and £80 current; and prize fund donations, £18 1s. The credit side shows £39 11s. 6d. for past and £512 16s. 6d. for current session, including rent of premises, £155; stationery, printing, and advertisements, £118 9s. 2d.; library grant, £10. The balance in treasurer's hands has increased during the year from £51 13s. 10d. to £112 14s. 4d., and after providing £40 for prizes and sundries, the balance of assets over liabilities in favour of the association is £953 13s. 10d.

The complete syllabus for the current session is as follows:—

- Nov. 11, 1881. Address from the President (Mr. Aston Webb).
- Nov. 25. "The New Examination and What it Involves," Prof. T. Roger Smith.
- Dec. 8. "Barnacles," Mr. Cole A. Adams.
- Jan. 6, 1882. "A Chat with the Younger Members on the Writing of Specifications," Mr. Ewan Christian.
- Jan. 20. "Architectural Inconsistencies," Mr. Philip E. Massey.
- Feb. 8. "The Treatment of Sculpture with Architecture," Mr. Hugh Stannus.
- Feb. 17. "Physical Science in Relation to Architecture," Mr. J. Slater, B.A.
- March 3. "Ideal Dwelling Houses," Mr. E. Ingress Bell.
- March 17. Members' Soirée. Members only admitted.
- March 31. "Sundry Working Drawings," Mr. J. P. Seddon.
- April 21. "Some Thoughts on the Principles of Design and Style in Church Architecture," Mr. B. E. Ferrey.
- May 5. "Coloured Decorations," Mr. G. Aitchison, A.R.A.
- May 19. "Markets," Mr. John Hebb. Nomination of officers.
- June 2. "The Influence of Ritual on Church Architecture," Mr. E. Eldon Deane. Election of officers.

A course of nine lectures on "The History of Architecture," will be given by Mr. E. J. Tarrver, in connection with the Class of Design, on Friday evenings at 6.30 p.m.; and a course of eight lectures on "Construction," by Mr. T. Blashill, in connection with the Classes of Construction on the same evenings, and at the same hour. The list of members published at the end of the volume shows a total of 691 resident in London, and 172 resident elsewhere, making together 863 names on the books. A striking illustration of the comparatively youthful period at which it is possible to rise to the chair of the Association, and of the continued interest shown in the Association by the senior members of the profession, is afforded in the fact that no fewer than nineteen members in the present list are distinguished by the prefix of an asterisk, denoting that they have served the presidential office.

A new and very useful feature of the "Brown-Book" is an appendix furnishing particulars of some of the other opportunities for carrying on special studies now afforded to architectural students. It supplies information as to the Architectural Examination, the Academy school, and the mode of obtaining admission as a student, the courses of lectures at King's and University Colleges, and the classes of the Royal Architectural Museum, the National Art Training School, and some particulars as to the Artists' Rifle Volunteer Corps, in which Companies D and E are enrolled from members of the architectural profession.

THE LATE MR. WILLIAM BRODIE, R.S.A.

MR. WILLIAM BRODIE, R.S.A., died on Sunday in Edinburgh. The deceased gentleman was a native of Banff, and in early life showed a taste for fine arts, painting, and sculpture, which he prosecuted in Aberdeen and

afterwards in Edinburgh. He, however, felt a greater aptitude for sculpture than for the sister art of painting, and studied in Rome. Returning to Edinburgh, he, in the course of a long and successful career, has, perhaps, executed more busts in portraiture than any other artist in the same line. A number of statues by him are placed in different towns in Scotland, among them being that of Dr. Graham Professor of Chemistry, in Glasgow, which is in bronze; the Prince Consort statue, at Perth, in freestone; the statue of Sir James Y. Simpson, at Edinburgh, in bronze; the statue of Sir David Brewster, in the quadrangle of Edinburgh University, in marble; the statue of Lord Cockburn, in Parliament-house, Edinburgh, in marble; and many of the statuettes in the niches of the Scott monument. In 1851, Brodie was elected an Associate of the Royal Scottish Academy; in 1859 he attained full rank as an Academician; and in 1876, on the retirement of Mr. J. D. Peddie, R.S.A., he was elected secretary to the academical body. As far as his work permitted, he kept himself up in literature, enjoying books of all kinds. He also studied architectural decoration, and turned his knowledge to good account in designs for monumental erections, usually in combination with sculpture, but not invariably so.

COST OF SITES UNDER THE ARTISANS' DWELLINGS ACT.

A FEW facts connected with the working of the Artisans' Dwellings Act, 1875, as reported by the committee of the Charity Organisation, may be of interest. From that part of the report of the Dwellings Committee dealing with the action taken under the Acts of 1875 and 1879, as given in the last return, dated January, 1881, we learn that in the City, where the Commissioners of Sewers constitute the local authority, two official representations have been made. Four areas, or 126,390 square feet, have been cleared for artisans' dwellings. The tenders received are at the rate of 3d. per foot, and the Home Secretary was applied to as to whether the ground-floor and basements can be utilised for shops and thus prevent a serious loss to the ratepayers. The report of the select committee, which we gave in outline (p. 547 ante), is to the effect "that with the view of lessening the expense of carrying out the Act of 1875, the confirming authority might well consent to the basement and ground-floor of any building being let as shops or workshops." From the facts stated it appears the net result in the City is that the Act has not yet been carried out in any instance, but that in about a third of the area represented it may be adopted with modifications. A table follows, showing an analysis of the return of the Metropolitan Board of Works, from which it appears that little, or almost nothing, has been done. In seven different cases of official representations, the areas are still under consideration or otherwise disposed of. We find 682 houses and 5 areas have arrived at this stage; in another instance 319 houses are regarded as too limited in size for the application of the Act; other houses are certified not unhealthy, or the cases have been withdrawn or otherwise not dealt with. No action has been taken with regard to 1,295 houses occupying 39½ acres and 5 areas, action has been taken regarding 1,402 houses, and areas comprising 945 houses and 6 acres have been sold and dealt with.

In the provinces we find the Act has made slow progress. In Birmingham an area of 93 acres, at an estimated cost of £1,310,000, is being dealt with. In Brighton, Dover, Exeter, Hastings, Salford, and Sheffield, the Act is under consideration; and we hear that in 77 towns no steps have been taken, and in no town have the proceedings under the Act been completed. At Liverpool, Norwich, Nottingham, Swansea, Walsall, and Wolverhampton, the Act has been in operation; the areas have been cleared or purchased. From the table given, the estimated nett cost per square foot is 5s. at Swansea, 7s. 6d. at Nottingham, and 6s. 2d. at Liverpool. The returns of the Metropolitan Board of Works show the cost of the areas to be at the rate of £2 17s. 5d. the square foot, after sale to the Peabody trustees, and of a part for commercial purposes. It is important to observe that had the land acquired been sold for commercial purposes only, the Metropolitan Board of Works would have acquired the areas

for street improvements, &c., at a cost of 13s. 10d. per foot. But the advantages purchased at the higher rate include the demolition of unhealthy dwellings, the opening out of proper roadways, open spaces round dwellings, and the erection of habitable houses. It is well asked whether it is worth while to incur this cost per foot for new dwellings on part of the cleared sites, when demolition and roadways can be purchased at a cost to the rates of 13s. 10d. per foot. Mr. Selway, in the Minutes of Evidence, estimated that on the various sites of the Peabody Dwellings, the prices sold at is equivalent to making each family a present of £250 out of the rates of the Metropolis. The fact simply told is that buying under the Act and selling for these dwellings necessitates a great loss, which can only be met by a less expensive rate of compensation to owners and lessees. The report shows further that rents have been raised by owners for the purpose of increasing the value of their property; the formalities in conducting compensations are long and expensive, and large sums of money have to be given for the trade and connection of low public-houses. Again, it is stated that by systematic distribution, economy of space and higher buildings, one-half more people might be housed. To acquire central positions at high rates, and erect artisans' dwellings on them, must incur loss. Dwelling associations ought to purchase land at such a rate as will enable them to make at least four per cent., and from the tables furnished it is clear that associations have purchased at cheaper rates without municipal intervention.

CHIPS.

An inquiry was held at Dover on Saturday before Mr. Stephen H. Perry, C.E., Local Government Board Inspector, with reference to an application from the Dover town council for sanction to borrow £9,500 for waterworks extension. It transpired that the town council had entered into a contract for the work before obtaining sanction from the Local Government Board, and the inspector said this could not be allowed to occur again. Considerable opposition was offered to the proposal by townspeople.

New Wesleyan Sunday-school buildings were opened in Wells City on Tuesday week. The schools adjoin the chapel and are built of local stone, with Doubling stone dressings. The chief room is 50ft. by 36ft., and the open-timber roof and seating are of varnished pitch-pine.

The town council of Guildford last week sealed the revised plan and specification for the superstructure of the proposed new bridge, as prepared by Mr. C. H. Sparkes, C.E.

The parish-church of Salhouse, Norfolk, which had long been in a disgraceful state of disrepair, has just been retored by Mr. John Oldrid Scott, from plans prepared by the late Sir Gilbert Scott. The reopening services took place on Tuesday last.

The Congregational Chapel at Ebley, Gloucestershire, was reopened on Thursday week, after rebuilding, and the erection of new organ. It now seats 600 persons. The architect was Mr. J. Thomas, of London, and the builders were Messrs English and Sons, of Stroud. The cost has been £3,215.

New board-schools at Hebburn, near Newcastle-on-Tyne, were opened on Monday week. They accommodate 800 children, and have been built by Mr. John Smith, contractor, of Jarrow, from the designs and under the superintendence of Mr. J. H. Morton, architect, of South Shields.

The town council of Accrington have decided to apply to Parliament, in the ensuing session, for powers to construct about 7½ miles of tramways, extensive intercepting and outfall sewers, precipitation works, a branch canal about a mile in length, and new store yard, with stabling sheds and railway sidings. The plans are being prepared by the borough engineer and surveyor, Mr. E. Knowles.

The late Mr. William Ward, who died on the 26th of October, has bequeathed the sum of £100 as a legacy to the Builders' Clerks' Benevolent Institution. Mr. Ward was the uncle of Mr. Thomas Peto Ward, the founder of this excellent charity, and the above bequest is the first that has been made to its funds.

A petition was filed in the Sheffield Bankruptcy Court on Saturday on behalf of James Joseph Donellan, builder and contractor, with liabilities estimated at £6,500. Mr. S. Lockwood Levick has been appointed receiver.

STATUES OF THE DOMESTIC VIRTUES.—THE "LOTHIANS."
HAMSTEAD.—CONGREGATIONAL CHURCH, NEW BARNET.
—LODGE, ELY GRANGE, FRANT.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ARTISTS' HOMES, NO. 16: "THE LOTHIANS,"
HAMSTEAD.

THIS house, situated at the Swiss Cottage end of Fitzjohn's Avenue, is from the designs of Messrs. Wm. Wallace and Flockharts. The walling is of red Suffolk brick, with Beer stone dressings, the roof covered with Whitland Abbey slates. The staircase is of wainscot; hall and vestibule floors laid with mosaic. As is to be expected in an artist's house, the studio is the principal feature in this plan. The room is one of the largest that has been built in London, having a clear floor space of 50ft. by 30ft. The builders were Messrs. S. Dowling and Son, of Notting-hill.

CONGREGATIONAL CHURCH, NEW BARNET, HERTS.

THE plan of this church consists of nave and aisles of the usual relative proportions, but there is only a single granite column on each side forming any appreciable obstruction to sight. From these spring two very wide pointed arches, covering the whole space occupied by the seats, and abutting on strong clustered shafts towards each corner of the building. These again carry small arches, the space inclosed by them being used as an organ-chamber and invalids' seats on each side of the pulpit, and towards the entrance end as part of a wide and spacious lobby stretching across the building. This is divided from the seated portion of the building by a glazed screen formed of a series of folding doors, which, when occasion requires, can be thrown open and the whole of the lobby used for extra sittings. At one end of the lobby (opposite the tower) is a cloak-room with conveniences attached, for the use of the congregation. As the ground slopes rapidly to the back, a large amount of space is available under the vestries, &c., and is used as an infants' classroom, with gallery for 80, and three good classrooms for about 25 scholars each, with the usual conveniences, heating-chamber, scullery, &c. The building is erected in stock bricks, faced externally with Kentish rag in courses, with Bath stone dressings, and internally with Beart's white bricks for plain surfaces, and mouldings, &c., in Bath stone. The spire reaches a height of 150ft. The buildings were very satisfactorily carried out by Messrs. L. H. and R. Roberts, of Islington, from the designs of Mr. John Salaman, of 1, Farnival's Inn, E.C.

STATUES OF DOMESTIC VIRTUES.

THESE statues have been designed and carved by Mr. John Roddis, of Birmingham, for the recently erected offices of the Scottish Provident Institution in that town. The building itself

is in the French Renaissance style, and was designed by Messrs. Osborn and Reading. The statues stand in niches, and are a little over life-size. It will be seen that the sculptor's aim has been to impart as much variety as possible in costume and general treatment.

THE ROYAL COURTS OF JUSTICE.

MR. W. ARMSTRONG concludes an illustrated description of the New Law Courts in the last number of the *Magazine of Art* with the following criticism:—

We have to offer in all humility a few criticisms upon what we conceive to be its architectural merits and demerits. To begin with the latter, it seems to us that Mr. Street's creation lays itself fairly open to the charge which has more than once been brought against it—of a perverse disregard of balance and symmetry in its masses. With the single exception of that part of the Strand elevation which is included between the two octagonal stair towers, there is not an instance of symmetrical repetition on a large scale in the whole exterior. On the other hand, there are many instances of what looks like carelessness, but is, in fact, studious—almost malicious—disregard of symmetry; and these are terribly destructive of architectural effect. Perhaps the most provoking of them is to be found on the Carey-street front, where the apex of the carved label over the central doorway cuts the sill of the great window above it into two very unequal parts. Similar failures of coincidence occur here and there throughout the building, and help to call attention to the lack of any governing artistic motive in the general design. There are six towers all different, though all of very squat proportions; there are eight facades, counting those in the great, or eastern, quadrangle, and they are all, with the doubtful exception of that which faces Clement's Inn, broken up into so many parts and into such unsymmetrical masses, that no one of them is much more expressive than if it were made up of half a dozen buildings by as many different architects.

Such want of coherence was appropriate enough in the great Mediaeval buildings upon which Mr. Street has modelled his art. They were usually the work of several generations, and as they received successively the impress of many directing minds, their irregularity was a natural growth, and was as true in expression as it was picturesque. In these days of what may be called Romantic architecture it is too often forgotten that a picturesque *ensemble* is in its very nature irreconcilable with a great artistic conception. The latter cannot exist without unity, symmetry—in a word, without individuality; but the qualities which make a building picturesque are identical with those which deprive it of individual expression. A picturesque thing is one which lends itself to pictorial treatment; that is, one which, being without any inseparable unique expression of its own, can be clothed in the personality of the painter, etcher, or other artist who may treat it. In this way our new Palace of Justice is more picturesque, perhaps, than any other modern building of equal importance. It would not be a hopeless task to make a good picture of it, because, by careful selection of the point of view, by combining the light and shadows, by repressing a little here and accentuating a little there, it could be turned, by the utterance of some painters' individuality, into a synthetic work at last. And we must admit that Mr. Street's analytical method has its compensations. In these courts of justice there is none of the thoughtless repetition of detail which disfigures so many great buildings. The sections of every door or window moulding, the designs for each carved capital, string-course, label, or dripstone, for each stair balustrade and stone chimney-piece, for every detail of groining or oak framing, have been the objects of his separate and individual attention. In this respect his work contrasts very greatly with that of many other architects. He appears to have a perfect horror of monotony, and to aim at making his building look as if its decorative details had been left to a crowd of separate and independent designers. Many of these details, however, are very beautiful. We may give, as an instance, the balustrades round the galleries in the central hall. These are Venetian rather

than English in design, and are carried out in a warm grey Derbyshire marble from Henton Wood, a large quantity of which is used for similar purposes in the building. One of these galleries—that at the northern end of the hall—seems to have been suggested to Mr. Street by a curious balcony or canopy which occurs in the Church of St. Peter, at Maid's Morton, in Buckinghamshire. The balcony in question is over the west door of the church. It is supported by two brackets, which are similar in form and detail to the pendentives of such fan-vaults as the roof of St. George's at Windsor, or King's College Chapel at Cambridge. These brackets rest upon engaged shafts, and the space enclosed by the whole is filled up by the doorway. Mr. Street's gallery is a repetition of this arrangement, with the exception that it is supported by three brackets instead of two, that there are two doorways between them, and that the details are, of course, Edwardian, while those of the Buckinghamshire church are Perpendicular. The way in which the gallery at the south end is supported is, on the other hand, clumsy in the extreme; it rests upon two huge and heavy stone corbels, which, in their turn, are each supported by a comparatively slender shaft of English marble, which appears quite unequal to the work which it has to do; but the minor details of the building are generally both beautiful and appropriate; and although the work, as a whole, must be denied the glory which belongs to a great artistic conception, it certainly deserves that which should be given to the effects of a severe taste and of an extraordinary power of work.

It is at present intended to lay out, as a garden, the space which intervenes between the western facade of the Royal Courts, and Clement's Inn; but it is certain that before many years have passed over us further court accommodation will be required, and an opportunity, which we sincerely hope may not be thrown away, will then be given of adding to the monumental effect of the Strand front by repeating its eastern wing.

SCHOOLS OF ART.

GATESHEAD.—The annual meeting for the distribution of prizes and certificates at the classes in this town took place on Wednesday week. The report stated that there were on the Barncliffe class-books 107 students, and that at the May examinations 84 were examined and obtained 17 Queen's prizes, including a bronze medal and 84 certificates. At the North Eastern Railway Institute classes there were 34 students, who had obtained seven Queen's prizes and 30 certificates. At the Prior-street classes, with 45 students, two Queen's prizes and 17 certificates had been gained; and at the Alexandra-road schools there were 108 students, against 57 last session: 43 Queen's prizes and 171 certificates were obtained at the examinations.

CHIPS.

The City Commissioners of Sewers have voted the following sums, equal to half a year's salary, to officers who have been engaged in carrying out the Artisans' Dwellings Acts:—to the engineer, £1,000; to the solicitor, £750; to the medical officer of health, £250; to the principal clerk, £100; to the first assistant clerk, £50.

The local board of Diss, Norfolk, is about to be sewered from plans by Mr. Thomas Reed, C.E., of Normanton, Yorks. The sewage will be conveyed about a mile in earthenware pipes, varying from 12in. to 21in. in diameter, and having been carried under the river Waveney in an iron pipe, will be received in a tank and settling-chamber, and disposed on the land.

A memorial stained-glass window to the late Dr. Copeman has been placed in St. Luke's Chapel, an ovate projection from the south-east angle of Norwich Cathedral. The subjects are treated in medallion style, and are three acts of healing performed by our Saviour. Messrs. Clayton and Bell, of Regent-street, London, have executed the work.

There is, it is reported, to be another effort made next Session to obtain a Bill for the construction of a new railway from London to Brighton. The plans are prepared, and show that the route will be by way of the Metropolitan District Line to Chelsea, and thence across the river to Shoreham and Brighton direct.

THE DISPOSAL OF REFUSE IN THE CITY OF LONDON.

A REPORT on the disposal of refuse from the City, with special reference to effecting it by the apparatus of Messrs. Manlove, Alliott, Fryer, and Co., engineers, of Nottingham, was presented to a Committee of the City Commissioners of Sewers on the 11th inst., by Col. Haywood, their surveyor. The refuse may be broadly divided into five classes:—(1) house refuse; (2) trade refuse; (3) market refuse (animal and vegetable); (4) street sweepings; and (5) condemned meat. All except the last class of refuse are now carted to Lett's Wharf, on the south side of Waterloo-bridge. There, the house and some of the trade refuse is forked over and sorted; leather, iron, glass, crockery, and certain other materials, are separated from the ashes, and sold to various dealers, the ashes and breeze are sifted and sold to brickmakers. All these materials are, with the exception of a trifling quantity of vegetable refuse, generally dry. Their removal from the wharf is made daily. The street-sweepings and the animal and vegetable refuse removed from the markets and from the premises of large traders are got rid of together; the market refuse is at once mixed with the sweepings when they are dry, or nearly so, and shot from the carts into barges which are always lying at the wharf ready to receive them. Barges leave with this material daily. The street-sweepings, when in large quantities and in a state of slop, are not at all times shot into the barges, but are thrown down on to the wharf and mixed with straw and dry materials; the water rapidly drains away from them, and the residue is then mixed with street-sweepings, stable manure, or other drier matters having manurial value, is cast into the barges and taken away by agriculturists, who purchase it. No materials liable to decompose or be offensive are removed from the wharf through the public streets; old iron, tin, lead, glass, leather, paper, and a few other hard materials alone are carted away, and of these not more than a load or two leave the wharf daily. All materials are, as a rule sold, and with some gain: under exigencies some may have to be given away, and on very exceptional occasions the Commission may even have paid for getting rid of portion of them. On the wharf is a chimney shaft, 120ft. high, attached to a furnace, in which are burnt baskets, matting, shavings, dry leaves, and various kinds of refuse worth nothing for sale, and injurious to the sale of the street-sweepings and market refuse if mixed with them. No registers of the weights of materials received at the wharf has been kept, but the numbers of loads brought into the yard have been recorded under the general heads of Dust and Sweepings, the first including all trade and house refuse, and latter all street sweepings and slop, a load roughly representing a ton of material. Last year, 1880, there were dealt with 31,161 loads of "dust," and 30,078 tons of sweepings, in all, 61,239 tons, and the quantity increases annually. The average of receipts and costs for the four years, 1877-80 has been: Receipts, by sale of manure, £1,919 4s. 10d., and of ashes and selected material, £3,587 0s. 4d.; total, £5,506 5s. 2d.; expenditure in sorting, sifting, and removal, was £3,811 18s. 3d., leaving a balance to credit of £2,194 6s. 11d. per annum. This does not, however, include the cost of collection in the City, or of cartage to the wharf. The wharf premises have been in use for a dozen years past, and were reconstructed in 1876, since which time no complaints have been made of smoke, of effluvia, or nuisance arising from them. Passing on to consider the apparatus suggested to be used for refuse disposal, Col. Haywood remarks that these consist of a destructor, a carboniser, a carcass-crusher, and a Firman dryer, which he inspected in operation at Leeds, Farnworth, and Warrington. The destructor is a furnace of special construction, into which the dust, ashes, and other refuse are thrown just as they are collected, without separating or sorting the materials. All is consumed in the furnace, which, in the first case, is lighted by cinders and materials selected from the refuse itself. The furnace is assumed to be continuously in operation, and great heat is necessary for its success; it leaves a residuum consisting of clinkers, which are sold for road-making or ground up into mortar. The carboniser consists of a furnace attached to a close iron chamber,

round which the heat circulates. In this chamber vegetable refuse is reduced to a charcoal, and the fumes given off are mingled with the products of combustion and destroyed. The carcass crusher is a modification of the ordinary bone crusher, used by artificial manure manufacturers, and consists of two pairs of toothed cylinders revolving with different velocities at some distance apart from each other. By its agency large masses of flesh and bone can be reduced to sizes suitable for being operated upon by the Firman dryer, which is an apparatus for reducing, by heat, to a dry, or nearly dry, condition, the previously-prepared meat and bones; the residuum comes out in the form of a coarse powder, somewhat resembling the manure made at Paris and other cities on the Continent from human excreta, commercially known as "poudrette," and is said to be very valuable as manure. It has been suggested by the medical officer of health for the City that a large establishment should be made at Golden-lane, to which house, trade, and market refuse, as well as condemned meat, should be carted and dealt with by a system combining destructor, carboniser, carcass crushers, and Firman dryers. This would involve the sacrifice of a large rent of the area for commercial uses, and would also necessitate the maintenance of two stations, Golden-lane and Lett's Wharf, a division of site and work not tending towards economy, in the opinion of the City engineer. Farther than this, the use of such a site, placed in the heart of a community, is not, he thinks, desirable. The apparatus would be efficient for the purpose, but he does not think the processes would be financially successful. Should the Committee think a fundamental alteration in the mode of disposal is needed, the City engineer recommends that experimental works should be erected at Lett's wharf on an area of some 6,700 square feet. On this could be erected a destructor of ten cells, capable of dealing with 10 tons of refuse per 24 hours, or more than half the City output, mortar mills, carcass crushers, and Firman dryers. Messrs. Manlove, Alliott, Fryer, and Co. tender to supply these as per plan and specification given with the report, for £6,605, to which would have to be added structural alterations at the wharf, estimated at £2,700. The Commissioners of Sewers have adopted the recommendation of this report.

THE BASILICA OF NOLA.

ONE of the earliest Christian churches, of the plan and decoration of which we have any precise account, is that built at Nola, about the year 490, by Paulinus, a wealthy Roman patrician, of which Lady Margaret Daville contributes a description to the *Antiquary*. Nola, said to have been founded by a colony of Greeks, was a town of some repute in Roman annals. Under its strongly-fortified walls the victorious career of Hannibal was checked by the Consul Marcellus. The birth-place of Augustus, it was there that the curtain fell on the long drama in which the dying emperor claimed, not unduly, the merit of having played his part well. But at the latter end of the fourth century Nola's title of honour was as the place of death and burial, not of Augustus, but of Felix, a Christian martyr and bishop, over whose tomb a small church had been erected in very early times. This church, however, no longer sufficed for the rapidly-increasing Christian community, and Paulinus, who, having renounced all personal use of his great possessions, had ample means at his disposal, undertook to build another.

The building of the church of Nola occupied three years, at least; and in the letters written by Paulinus during that period to his friend Septimius Severus, the general design and decoration are minutely described. Other details have been gleaned from his poems and miscellaneous writings.

The plan was that of a basilica with an apse, or, as it was then more frequently termed, a bema; two rows of columns divided the main portion into a centre and two side aisles. Into the outer walls of the aisles were built little chapels or cellæ, destined for special purposes: some probably for private prayer, others as places of burial for the dead, who, according to the custom of the time, lay in the House of God, awaiting the resurrection. The altar was at the junction of apse and nave. The outer façade had three doors, and the building was turned,

not as was usually the case, eastwards, but to the tomb of St. Felix. A ruined church which filled up the space between the basilicas, was pulled down, and openings made in the wall of the older one, corresponding to the three doors of the newer, so that a full view could be had from the one church into the other. They were connected by a vestibule, in the centre of which a fountain threw up its crystal waters, while the walls were covered with inscriptions in mosaic. A distich over the entrance gave the salutation of peace to all who entered the sanctuary with pure hearts. On each of the side doors of the basilica of Paulinus was painted a cross, wreathed with flowers, on which doves nestled; over one an inscription, which was as follows:—

"See, in the atrium of Christ, this crowned cross; it is the symbol of the rewards which await our labours: take up the cross, all ye who would bear away the crown."

Underneath was written:—

"By the virtue of thy cross make us die to the world, and the world be dead to us. May death to sin give our souls life; of us too, O Christ, thou wilt make thy beloved doves, if peace dwell in our purified souls."

The inscription over the centre door ran thus:—

"As Christ our peace has filled up the gulf which divided the two nations, and breaking down with His cross the wall which separated them, of the two has made one; so see we here, after the destruction of the older building (it will be remembered that a former church had been removed): the two basilicas are joined and united. Here, too, a fountain lends its waters to those who would wash their hands before they enter. In the double sanctuary of Felix the people adore Christ. Paul, the bishop, rules them by his word."

The great door of the new basilica was also surmounted by an inscription, telling that it was consecrated by Paul the Bishop to the blessed celebrations; it is characteristic of Paulinus that each time the foundation of the basilica was alluded to, the name written on the marble was not his own.

Over the arches which formed the outer court of the basilica, Paulinus had built rooms for the use of pilgrims. Beyond, to the right, was a larger atrium, which he called the *area interior*; it was surrounded on the four sides by pillars, and open to the sky. In the centre rose a beautiful fountain, and at the corners four smaller ones richly sculptured: to supply them, piping had been constructed outside. This outer court is frequently alluded to by Paulinus in his poems; he delights in telling how the pilgrims, resting between their devotions, used to pace the cloisters, sheltered alike from the summer heats or the winter storms, then leaning against the balustrades which linked the columns, watched the sparkling waters break forth with joyful and pleasant sound.

The internal decorations of the basilica were no less carefully executed. The choir was formed by a triple apse (*trichora*), of which the central portion was considerably the largest of the two side recesses, called by Paulinus *secretaria*; one served as a receptacle for the sacred vessels and sacerdotal vestments; in the other were deposited the liturgical books and Sacred Scriptures. It was likewise used as a place for private prayer and meditation. The sanctuary was paved and its walls incrustured with precious marbles. Above glowed a lustrous mosaic, which, by symbols familiar to the Early Church, recalled to the worshippers the principal mysteries of the faith—the Trinity, the Incarnation, the Atonement; a hand issuing from a cloud symbolised the Eternal Father saying, "This is my beloved Son, in whom I am well pleased." Beneath were the mystic Dove, and the Lamb of God bearing the cross on which he was immolated. The cross was red, surmounted by a crown of light, signifying the royalty of Christ, who by the shedding of his blood had conquered the world. On each side of the cross were grouped doves, representing the twelve Apostles. The feet of the Lamb rested on a rock, from which issued four streams of living water—the four Evangelists. A long inscription (for in those days, when men's eyes were not wearied by printing, the architect was sure of readers) made the meaning of it all familiar to the people. Standing somewhat forward at the entrance of the nave was the altar, covered with rich veils. Over it was suspended a cross, enriched with precious stones and goldsmith's

work, and bearing and monogram of Christ; while from the roof hang lamps of silver and of crystal. The walls of the basilica were covered with pictures of sacred subjects, principally taken from the Old Testament; some, illustrating the deliverance of the Israelites from Egypt, had, to those but recently themselves liberated from a yet more terrible bondage, a special interest. What value these mosaics may have had as works of art we have no means of judging; only from the circumstance of their being alluded to by Panlinus as done *in raro more*, it is likely they were of the best work procurable at the time, and that, had they been preserved, they might now serve as connecting links between the rough, unskilful symbolism of the Catacombs and of San Clemente, and the majestic, awe-inspiring forms that look down on us from the darkening gold of the domes of Ravenna. But no trace of fifth-century work remains at Nola. Its cathedral has been rebuilt again and again; and even the keen eye of the Cavaliere Rossi has only succeeded in discovering, built here and there into the modern masonry, some fragmentary inscriptions, which, alike from their evident antiquity, and from the spirit of love and charity which they breathe, may be accepted as coming to us straight from the hands of Panlinus of Nola.

THE RECENT TURNERS' EXHIBITION.

IN our recent notice of the Turners' Exhibition, we spoke in praise of the objects submitted by Mr. J. S. Coulson, of Thirsk, to which the first prize was awarded. A correspondent of the *English Mechanic and World of Science*, who is evidently familiar with Mr. Coulson and his workshop, sends to that journal a photograph of one of the pairs of vases. He says:—

It will be remembered that Mr. Coulson gained the second prize last year, on that occasion also with a pair of vases somewhat similar to those exhibited this year. The latter are superior to the former in being more chaste in design, and more carefully executed. The material used is laburnum inlaid with purple-wood, and the surfaces of the vases, which are exactly alike, are perfectly smooth, and are French-polished. It may seem surprising to some that specimens of turning so simple in design, and so free from complications, should gain the first prize; but it should be remembered that skill in turning is not so much shown in the production in ivory and hard wood of highly elaborate

work, done more by scraping than by cutting, as in the successful execution of simpler designs in the softer woods. The specimens submitted by Mr. Coulson furnish us with almost perfect examples of this, the highest branch of wood-turning. I say "almost" perfect, because one scarcely likes to fix a limit to human skill; but it may be safely said that anyone who sets himself to produce better work, will have a very hard nut to crack. Mr. Coulson is a joiner, cabinet-maker, and wood-turner by trade. His workshop is situated up a narrow passage, in one of the leading streets of Thirsk, and is so choked up with wood, and a miscellaneous collection of things in general, that it is with difficulty one can move

about in it. Mr. Coulson is at all times willing to show his lathes and specimens of work to those who are interested in such matters; but if anyone expects to see a hundred-guinea lathe by Holtzapffel, with appliances costing as much again, he will be disappointed.

BUILDING NEWS DESIGNING CLUB, 1881-1882.

NUMEROUS requests having been made to us to reopen the Designing Club, we publish to-day the first list of subjects with the rules of competition.

RULES OF COMPETITION.

1. Drawings to be sent in 28 days after the publication of the list of subjects.
2. Usually two subjects will be given every month, from which a competitor may choose.
3. The drawings to be executed in firm black lines on white drawing-paper, in sheets of the absolute size of 22in. by 11in., with no washes or tinting in colour whatever. Outline to be the first consideration; but drawings may be slightly shaded with shadows executed wholly in line. Sectional parts to be shown in ruled "hatching," or blocked in. The scale to be used will be given with each subject.
4. Drawings to be forwarded unmounted, by post, care being taken to roll the short way of the drawing, as packages over 18in. long are not transmissible through the post.
5. On entering the class (which may be done at any time) each competitor is required to furnish his name and address, which must be written legibly on the back of each drawing, as a guarantee of good faith, the *nom de plume* the author intends to adopt being boldly marked on the front of each separate drawing.
6. Prizes of £10 10s., £5 5s., and £3 3s. will be awarded to the best series of designs, such series not to consist of less than twelve subjects. Our decision to be final.
7. Before awarding the prizes any contributor will be expected to furnish proof, if necessary, as to his age, and the time during which he has been engaged in professional pursuits, though no candidate need be strictly an architectural student.
8. We reserve the right of arranging the drawings for publication in any manner we deem necessary.
9. A critical notice of the designs sent in of each series will be given in an early issue following the receipt of the drawings.

LIST OF SUBJECTS.

- A. A pair of model cottages for labourers, suited for a rural site. A living-room, scullery, and three bedrooms, with necessary conveniences. Economy of arrangement and style will be considered of the first importance. Drawings to comprise plans, section, and two elevations to an eighth of an inch scale, and details to half an inch to the foot.
- B. The treatment of a small staircase and entrance-hall to a villa. Hall to be 15ft. by 8ft. and 10ft. high in clear; a window to be provided on one side. Drawings to be made to fin. to the foot.

The directors of the Felixstowe Railway Company signed on Saturday a contract with Messrs. Lake and Co. for the construction of a deep-water tidal basin at Felixstowe, with an entrance 100ft. wide into Harwich Harbour, and with a depth of 23ft. at low water. The contract includes the making of a railway upon each side of the basin in connection with the main line, and also the erection of warehouses. The contract price is £50,000.

The paltry deal seats which have so long disfigured the nave of Durham Cathedral are being removed, and good oak seats, from designs by Mr. C. H. Fowler, F.S.A., are taking their place. New oak book-stands are also being placed in the choir, adding greatly to the convenience of those engaged in the services. The work was placed in the hands of Mr. Grabon, of North-road, Durham, and Mr. Roddis, of Birmingham, has executed the carving.

The Barton-on-Irwell Conservative Club, which is situated in Monton-road, Eccles, was opened on Tuesday. The building occupies an area of about 3,000 superficial yards. The total cost has been about £1,000. The club has been erected, from plans furnished by Mr. H. Lord, John Dalton-street, Manchester, by Mr. W. Brown, of Salford.

Building Intelligence.

COLCHESTER.—The repair of the Church of St. Martin, Colchester, is now about to be commenced. This beautiful and interesting church has in the course of years been reduced to a state bordering on ruin. It was inspected by the Royal Archaeological Institute on the occasion of their visit to Colchester in 1876; and at the suggestion of the late Sir G. G. Scott, the chancel ceiling was stripped, and the fine 14th-century curved-rib roof exposed to view. The present reparation is, for lack of funds, confined to the works most urgently required to preserve the fabric from the destructive effects of the weather, and includes the removal of ceilings, and the opening and repair of roofs. The works are under the direction of Mr. Edward J. Dampier, of Colchester, the contract being taken by Messrs. Gardner and Son, of Coggeshall.

DUBLIN.—The new South City Markets, Dublin, were opened on Wednesday week. The architects are Messrs. W. and R. Mawson. The building contract was given to Mr. Thomas Hall Thorpe, of Leeds. The space actually occupied by the building is about 1½ acres, but the site acquired by the Company for the markets, a portion of which has been used to widen the four surrounding streets, covers 2½ acres. The principal facade in South Great George's-street partakes of the Gothic style, with an intermixture of Flemish ornamentation. It has a frontage here of fully 300ft. The entire block occupies a square, with four entrances. The slating on the roof covers an extent of 2 acres, glass 1½ acres, plaster-work 8 acres, painting work 6 acres, wood partitions 1½ acres, wood skirting 4 miles, wood architrave moulding 4 miles, and plaster cornices 3½ mil s. There are 41 iron columns in the market-hall.

EBBERSTON.—The parish-church of Ebberston, Yorks, was reopened on Tuesday week, after restoration begun in 1869, under the superintendence of Mr. Ewan Christinn, and carried on throughout according to his plans. The tower has been carefully restored, much of the walls of the nave and chancel rebuilt, the former rough roof of oak and fir, with lath-and-plaster ceiling, has been replaced by an open roof of pitch-pine, the pillars, arches, and other stonework carefully cleared of plaster and colour, washed and repaired where necessary; the chancel arch entirely renewed, new stone windows inserted, the old damp floors removed and solid wooden ones laid down with proper ventilation, the whole church reseated with open pews, new pulpit, prayer-desk, altar-table, and choir-stalls, the floor of the chancel being laid with encaustic tiles, the decayed porch removed and replaced by a new one of Norman style. The restoration has been carried out by Messrs. Metcalf and Mr. F. Thorp.

EDINBURGH.—North Merchiston Established Church, Edinburgh, has made rapid progress during the past six months; the side aisles are roofed, and the main gables are almost completed. The church will accommodate 1,000 without galleries. It is in the Gothic style of the 13th century. The plan consists of a nave and side-aisles, with a small transept for organ at the east end of the north aisle, adjoining which is the vestry. The principal entrance is at the other end under the tower, the base of which forms the porch, while to the west of this is placed a session house, a hall for prayer-meetings, &c., a commodious beadle's house, &c., so that the total length of the buildings is 197ft. The width of the church inside is 62ft. 6in., and the height from floor to top of ridge is 66ft. The tower is nearly 30ft. square, and rises to a height of 134ft. 6in. above the road. The architect of the building is Mr. Honeyman, of Glasgow.

HALIFAX.—To St. Augustine's Church, Hanson-lane, the nave and transepts of which were erected from the designs of Mr. Coad, of London, a chancel has just been added from plans by and under the superintendence of Mr. C. F. L. Horsfall, of Halifax. The recent addition, which is to be opened to-day (Friday), is apsidal in form and 40ft. in length; the three faces of apse are each occupied by a two-light window 22ft. high with cusped circular head. The internal walls are lined with ashlar masonry, the floor is laid with encaustic tiles, and the

roof, choir-stalls, kneeling-desk, credence table, screens to organ-chapel, and vestry are of pitch pine. The reredos is of Caen stone, with black marble shafts dividing into panels; the central space is occupied by the *Angus Dei*. The window above in centre of apse is filled with stained glass, the subjects being the Crucifixion and the Resurrection. A new pulpit, of Caen stone, with rich marble steps and octagonal in form, has been placed against the north-west angle of chancel arch. The organ chapel measures 22ft. by 16ft. Messrs. Drake and Riley have been the masons, and Mr. John Mansley has been the joiner. A vicarage house is being built next the church, and the only portion of the scheme remaining to be carried out is the tower and spire.

MIRFIELD.—On Tue-day the new church of St. Paul, which has been erected at Easthorpe, Mirfield, was consecrated. The foundation-stone was laid in January last, and its erection proceeded very rapidly, under Messrs. Milner and Son, the contractors. The architect is Mr. W. S. Barber, of Halifax. The walls are faced with polished local ashlar. The columns of the arcades are Dalbeattie granite monoliths placed upon octagonal stone bases. There are seven bays to form the nave, and a wide chancel. The building really forms a parallelogram. There is a small tower, but it is carried to no great height. It is surmounted by a gabled roof, upon which is a wrought iron cross. The style is 14th century. The cost has been defrayed by Mr. E. B. W. Balme, of Cote Wall; Mrs. Hague, of Crow Nest, Dewsbury, and Mr. Charles Wheatley, of Sands House, Mirfield.

PAIGNTON.—The old churchyard having for some years past been dangerously overcrowded, it became absolutely necessary that a new burial-ground should be formed. After careful inquiry, the local board purchased two acres of land for £100, in a convenient position. The main portion of the cemetery is a parallelogram, and the paths have been formed square with the sides, by which means much space is saved in laying out the grave-spaces. The boundary-walls on two sides are 6ft. high, and consists of red-rock rubble-wall, coped with limestone "Scotch" coping. On the other two sides, which adjoin roads, the walls are 3ft. high, of tooled limestone, square-tuck pointed, and coped with chamfered Portland stone, having 4ft. high ornamental railing fixed in it. The entrance-way has a pair of handsome iron gates, hung to nicely-worked stone pillars. The contractor for the railing and gates was Mr. R. Waycott, the cost being £230 (painting, extra £20). The contractor for the masonry was Mr. Evans, and the cost £335. The plans of the two chapels were prepared by Mr. W. G. Coudry, architect, Paignton. The chapels have been erected by Messrs. Webber and Wallace, the cost of both, under one roof, being only £428. They are plain, but substantial, the walling being hammer-faced, square-pointed red rock, with quoins and window-dressings of white brick. The whole of the woodwork is of pitch-pine, the seats and other interior work being slightly stained and varnished.

PLYMOUTH.—The foundation-stone has just been laid of four blocks of dwellings which are now being erected by the Plymouth Workmen's Dwellings Company, Limited, on an exceptionally open site adjoining the manufacturing end of the town. The buildings, which are to be 4 stories high and on a somewhat new principle, will contain accommodation for 96 families in 256 rooms, exclusive of washhouses (with drying areas attached), pantries, coal-bunks, and cupboards, w.c.'s, and urinals. Each landing will contain provision also for drawing water, and for the removal of dust (in shoots) and dirty water. The w.c.'s are separate for the sexes. The buildings will be constructed in a most substantial manner. Great attention has been paid to the sanitary arrangements. The contractor is Mr. Philip Blowey, of Buckland Monachorum, and the architects Messrs. Hine and Odgers, of Plymouth. It is anticipated that the new dwellings will be quite as successful financially as those recently erected in Lower-street from the designs of the same architects, and which pay a clear 5 per cent. after making due allowance for voids, &c. The rent charged for each dwelling (including use of washhouse and all domestic conveniences) is only 2s. 2d. per week, except where two bedrooms are attached instead of one, in which case the rental is 3s. 3d. per week.

RATBY.—The parish church of Ratby, in the diocese of Peterborough, was reopened by the Bishop on the 25th Oct., after having undergone a partial restoration under the superintendence of Mr. Nicholas Joyce, A.R.I.B.A., of Stafford. The work carried out includes the following:—The whole of the roofs have been renewed and covered with local (Swythland) slates. The nave and aisle have been fitted up with new benches of pitch-pine, and the chancel with stalls of oak. A new vestry, with chamber for heating apparatus underneath, has been constructed on the north side of the chancel. The old brick porches have been removed, and a new porch of stone built on the north side. The nave arcade has been restored, and the decayed stonework in the walls, as well as the windows, doorways, plinths, and string-courses have been cut out and replaced with new stone. In the floor of the church were a large number of memorial slabs. These have been replaced in the positions they formerly occupied in the passages, the spaces between the slabs being made up with the new slate paving. The pulpit is of Caen-stone on a shaft of red stone. It is circular in plan, and has a richly carved capping. In front are figures in low relief of St. Philip and St. James the Less. A well-executed stained-glass window, by Mr. Francis A. Oldaker, of Epsom, has been placed in the south aisle as a memorial to the Geary family. The committee have already expended over £3,000. The restoration of the south aisle and the west tower remain to be done. The contractor is Mr. James Stanford, of Ashby-de-la-Zouch. The hot-water apparatus is the work of Messenger and Co., of Loughborough, and Thos. Brawn and Son, of Birmingham, have executed the ironwork.

ST. EWE, CORNWALL.—The parish-church of this village, situated some five miles south of St. Anstell, has been restored, from the designs of Mr. J. Piers St. Aubyn, architect, of the Temple, London. The edifice consists of nave, south aisle, chancel, north transept, two fine porches, and a western tower and spire. The latter is an interesting feature, spires being extremely rare in Cornwall. St. Ewe is also celebrated for its fine old oak Perpendicular rood-screen. This is one of the very few remaining in the county, and is by far the handsomest example existing in that far-off western land. The altar-plate, presented to the church by one Jacob Robins, of Tregenna, so long ago as 1695, is massive and of good design. During the progress of the restoration, several highly interesting archaeological remains were discovered. They have been carefully preserved to the church by Rural Dean the Rev. A. Lawrence, vicar. Most of the windows are new, well wrought in Wild Duck stone, and filled with painted subjects. The glass is by Messrs. Heaton, Butler, and Baynes, of London, and by Messrs. Fouracre and Watson, of Plymouth. The old carved waggon-headed oak roofs in the south aisle and north transept and porches have been restored. Those covering the nave and chancel are new. The chancel floor and the approaches and avenues are laid with encaustic tiles. The benches are of pitch-pine; so is the parclose screen and the stalls. The rood screen has been re-fixed on a new sill, in its original place between the nave and chancel; it has also been lengthened several bays, the new work being of the precise character as the old. The coats of whitewash and of varnish have been removed, and the various coats of arms have been renovated. This screen is groined on both sides, and hence has a famous wide rood-loft over the cornices. Its restoration was undertaken by Mr. Harry Hems, of Exeter. The contractor for the general works was Mr. W. May, builder, of Pool, near Camborne. The cost of restoration has been £2,500.

SWINDON.—The cemetery here is now complete. The site is eleven acres in extent. The buildings consist of chapel, care-taker's lodge, and mortuary, and are built of local stone, with Bath stone dressings. The chapel is in the 13th-century style, and will accommodate 100; it has an apsidal end and a bell-turret; the roof is covered with Bangor slates and bands of green. The fittings are of pitch-pine; the tiles are from Minton, Hollins, and Co. The carving has been executed by Mr. Chapman, of Bath. The work has been carried out from the designs, and under the superintendence of Mr. W. H. Read, architect, of Swindon, whose plans were selected in a limited competition. The con-

tractors are Messrs. Phillips and Powell, and G. Wiltshire, jointly, and Mr. Gilling has acted as clerk of works. The total cost is about £10,000.

WINSFORD.—Winsford Weaver Navigation Church, which was erected less than 40 years ago (Mr. Edmund Sharpe, of Lancaster, being the architect) has had to be taken down in consequence of the serious subsidence which has taken place in the salt districts of Cheshire, and the River Weaver Trustees have instructed Mr. Richard Beckett, of Hartford, to re-erect the same forthwith. The structure will be built on the same foundations as before, using the old roof, seats, and fittings; but the walls are now to be built on the half-timber principle, of strong timbers filled in with brickwork on lifting beams, so making provision for lifting in case of any future subsidence. Mr. Beckett has recently lifted the Town Bridge a height of 4½ ft., under the direction of Mr. Stanhope Bull, the county surveyor. The town hall (with five shops, a corn warehouse attached, &c.), was also lifted by the same contractor, about two years and a half ago, a height of 8½ ft.

ARCHÆOLOGICAL.

ANTIQUITIES AT ROYSTON.—The Cambridge Antiquarian Society visited Royston on Tuesday week. The Cave was seen under the guidance of Professor Hughes, who remarked upon its position at the junction of four parishes, and called attention to the rudely-cut figures and other carvings on the wall, which he attributed to the 11th or 12th centuries. It might have been a hermitage or prison. The Rev. S. S. Lewis said the cave was at the junction of two Roman roads, the Icknield-way and Ermen-street; the figures on the walls represented the high altar, St. Catherine, St. Christopher, St. Lawrence, St. John, and St. Thomas of Canterbury. A hermit of Royston existed in Edward VI.'s time; but there was no intimation that he lived in this cave; the only bones found in it were those of domestic animals. The priory church was next visited, Mr. W. M. Fawcett, M.A., explaining its leading features, and expressing his regret that the fine chancel-screen, described in Cusson's "History of Hertfordshire," had been removed in modern times. Mr. Bendall said the screen was cut up and reformed into the present pulpit and reading desk; the original font was turned out by the late vicar, and was bought from the stonemason's by a farmer who used it as a trough under a pump. It had eventually been purchased by a neighbour, Mr. Phillips, to place in his garden.

BRISTOL.—An interesting archaeological discovery has been made on the premises of Mr. H. Boxall, 19, Mary-le-Port-street, Bristol, during some alterations. A fine freestone mantelpiece, ornately sculptured, and bearing a shield charged with the arms borne by George Harrington, Mayor of Bristol in 1617, having been exhumed from a thick covering of mortar. It is being carefully restored under the supervision of Messrs. J. W. Trew and Sons, architects, of 56, Broad-street. Harrington's residence, whilst mayor, was in Corn-street. Mr. J. F. Nichols, City Librarian, points out that this coat, which in the Mayors' Calendar is ascribed to the above Mayor, is there tintured incorrectly, colour upon colour, thus Gules on a chevron sable, three tuns, or, between six garbs (wheatheaves) placed in pairs salterwise, two one and one, or. Of course, the stonework shows no tincture, and the ordinary and devices are as above. The curious thing in connection with these arms is that they occur twice in the same street—viz., on the fronts of Nos. 38 and 40, below the first-floor windows. This raises a question as to whether these were not the arms of the Brewers' Company of Bristol, and were born by Harrington with a difference for his own coat, he being a brewer, just as Robert Aldworth bore for his coat the arms of the Merchant Venturers with a difference.

A stained-glass window has been placed in the south side of choir at Painswick parish-church. The subject is the Adoration of the Magi. Messrs. Hardman and Co., of Birmingham, were the artists.

The first ordinary meeting of the session of the Surveyors' Institution will be held on Monday evening, at 8 p.m., when the president, Mr. Edward Ryde, will open the session with an address.

"To a practical man with a taste for mechanics, and the bumps of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion.—*The Brightonian*. Price Two-pence of all newsmen, or post free 2d.—31, Tavistock street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eighth word after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 80c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.
Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL., Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—J. K. and Son.—V. and Co.—J. W.—B. and S.—W. T. and Son.—W. B. S. and S.—B. S. and H.—G. B. and L.—D. and C. O. E.—L. F. Co.—H. C. and Co.—J. M.—S. and Co.

H. H. B. (The material is dextrin or "British gum." It is made by subjecting starch to a heat of 600°)—S. WILTSHIRE. (Write to B. T. Batsford, 52, High Holborn.)

Correspondence.

THE DUBLIN MUSEUM COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—Dublin Museum competitors should ask the Treasury to require from each member of the committee of selection, before acting, a statement that he has not seen any design, nor been canvassed, directly or indirectly.—I am, &c., FAIR PLAY.

PARC GWYLLT ASYLUM, GLAMORGAN.

SIR,—The statement contained in your issue of last week being calculated to mislead, and likely to injure us professionally, we must ask your insertion of the inclosed resolution of the committee, which puts the matter in its proper light.

On August 11th, 1881, meeting of committee resolved—

That Messrs Giles and Gough be requested to prepare a plan of each floor of proposed Asylum for 700 patients to 1 16th scale, together with sketch elevation, for submission to Quarter Sessions and Lunacy Commissioners, for the sum of £350 in event of work not proceeding to merge into usual commission as works proceed.

On Sept. 9th, when the sketches were submitted, resolved—

That the plans be approved and be submitted to the Court of Quarter Sessions.

We are, &c.,

JOHN GILES & GOUGH.

28, Craven-street, Charing-cross, Nov. 2.

WATER-TRAPS AND SIPHONS.

SIR,—I fear I must enlarge the historical data somewhat which Mr. Davies gives at page 492, where he says Mr. Jennings was one of the first to use a ball inside a trap, his first patent being dated 1871. Now, permit me to state that long before this, viz., in 1834, Mr. Rawlinson, C.E., invented a ball-trap. Then in 1863 Mr. Fenwick brought out another one, while in 1866 Mr. Williams, an American, invented a ball-trap, in which the ball lay in the outer limb of the siphon trap, below the water, just as does the ball in the trap invented by Mr. Davies (as he candidly tells us on page 575) ten years after. In the ball-trap (Fig 101, page 459) invented by me, the ball is placed above the water, in which respect it differs from both Williams' and Davies' traps. I make little account of this trap myself, and have repeatedly pointed out that these ball-traps, supposing they were "perfect" *per se*, were useless for doing any good in case of a leak in the pipe beyond the trap. To protect the inmates properly, the waste-pipe I pointed out had to be protected. This confession and information does not, of course, please quacks who have perfect cure-alls to sell.

In regard to Mr. Davies thinking "Mr. Buchan is not a careful reader," because I stated on page 545 that the ball in Jennings' "perfect" trap would only be a "sham sentinel" if a hole got into the water trap or into the metal above it—I have re-examined the drawing (Fig. 103, page 492), and repeat what I said.—I am, &c.,

W. P. BUCHAN.

[We have no further space to spare for this discussion.—Ed.]

PRACTICAL EXPERIMENTS WITH CLOSET-TRAPS.

SIR,—Mr. Emptage has, I think, scarcely paid sufficient attention to my diagrams, by which I endeavoured to show the result of practical experiments on traps. If he will refer to 5, Fig. 3, he will see that without any pipe at all upon the outlet, the momentum is precisely the same as if there were 100ft. of pipe.

With regard to the 2in. ventilator that he has suggested, I must say that his idea is the same as Mr. Ernest Turner and Mr. Rogers Field. These gentlemen had a 1 1/2in. hole cut in the top of one of Beard and Dent's "O"-traps, when they of course found the result the same. Now, referring to Mr. Emptage's remark as to the efficacy of the T-trap under a valve-closet, allow me to tell him that Mr. J. Clark (Beard and Dent's foreman) has asserted, in presence of others beside myself, that they never fix a T-trap under a valve-closet.

But to clear up this matter finally, we have fixed a valve-closet over one of Beard and Dent's half O-traps, when the trap momentum out every time a basin of water was discharged. We did this with a 1 1/2in. air pipe, also with trap open at the top, and again without ventilation excepting at the soil-pipe. In all these cases the result proved to be precisely the same.

In reply to "W. N. O." I think the first three paragraphs are answered in the above letter, and with regard to the Eclipse trap, I must acknowledge that I overestimated its capacities; but on finding by the test in what points it failed, I hastened to explain it to my readers.—I am, &c.,

P. J. DAVIES, II.M.A.S.P.

THE BIRKENHEAD v. THE GLASGOW TOWN-HALL COMPETITION.

SIR,—There is one feature in the Birkenhead conditions that is at least suggestive. Although modelled on the Glasgow conditions, those for Birkenhead differ in this: that the guinea charged for conditions is a deposit, not a payment. Considering the work involved in the preparation of the drawings is infinitely less in the Birkenhead than the Glasgow competition, the large-heartedness of the English municipal body contrasts favourably with the niggardliness of the wealthy Scotch corporation.—I am, &c.,

A SCOT.

The annual distribution of prizes and certificates to the students in the science and art classes at Ashford, Kent, took place on Thursday week. The report was of a highly encouraging character.

The Town Council of Scarborough at their last meeting accepted tenders amounting to £9,216 16s. 10d. for constructing new sewers and carrying out improvements to causeways from the plans of the borough surveyor, whose estimate for the work had been £7,000.

At a special meeting of the City of Wells Town Council held on Wednesday week it was decided to carry out works of sewerage disposal, as recommended in the report of Mr. Ellis, C.E., in which a process of deodorisation, filtration, and precipitation will be adopted. The estimated cost is £3,865 for works and plant, and £1,500 for purchase of land.

Entercommunication.

QUESTIONS.

[6746].—**Architect's Account.**—Can an architect be compelled to supply a client at the termination of a contract, with a complete detailed bill of extras and omissions containing the builder's prices, or is an abstract or summary all that the owner can legally claim?—MAX-CUSIAK.

[6747].—**Thatched Churches.**—Do any old churches with thatched roofs still remain in England?—G. C.

[6748].—**Palace for Guicowar of Baroda.**—Will some one give the leading dimensions, or supply the scale for the plan of above, as given in the BUILDING NEWS of the 28th October, 1881?—INDIA.

[6749].—**Commonplace Book.**—I am about to enter an architect's office, and wish to keep a commonplace book. Being rather at a loss how to set about it, would some of your readers oblige by giving a few hints?—L. E. K.

[6750].—**Removing Oil Stains from Paper.**—I have just had some books and drawings stained by the oil from a lamp accidentally overturned, and shall be thankful if any correspondent can inform me of means by which the stains can be removed.—NEWTON ABBOT.

[6751].—**English Buildings Previous to the Conquest.**—Can any of your readers refer me to a list other than the one in Rickman) of buildings, more particularly churches, which were erected previous to the Conquest, and of which remains are still left?—F. P.

[6752].—**Zinc Roofs.**—I have a flat about 24ft. by 18ft. that I intend covering with zinc. The fall will be in one direction, from a wall to the eaves. Can any one inform me where I can obtain the best quality zinc for the purpose, as to best way of laying it, length of time it would last, and best way to secure the zinc at eaves and verges. Any information on the subject will be very acceptable.—ZINC.

[6753].—**French Casements.**—I am about to fix in a library somewhat exposed casement windows opening down to the floor. The sill I thought of having in oak, the other portions pitch-pine. Can any reader inform me if the wood I propose for the sill is a good one to stand for that purpose? Also, I shall be glad of a sketch or section of a good casement of the description named, to be water tight and of good appearance, showing sill, bottom rail, and the transom with top rail; also meeting stiles, mullions, &c. Some of the casements open inwards and others out. Also where the best description of fastenings may be obtained for the casements in question.—READER.

[6754].—**Chimney Shaft.**—I shall feel obliged if a contributor to your "Intercommunication" column would inform me where I could see in course of erection a chimney shaft, about two hundred feet high.—W. HICEST.

[6755].—**Oak.**—1. What is the difference between brown and white English oak, and to what purpose is each kind put? 2. Is it a fact that the importations of foreign oak have been doubled during the last seven years, and much to the depreciation of English oak? 3. In what part of the metropolis is most English oak used, and from where is it principally supplied?—YONGE OAK.

[6756].—**Pointing.**—Would some practical reader kindly inform me what is the best to use for pointing the joints of outside walls of a mansion which is built of limestone?—M. N. O.

[6757].—**Road Surveyor, &c.**—Will some kind reader of this valuable paper advise me a would-be road surveyor and sanitary inspector as to the best work on this subject I could get to read up from, also price of same, and oblige.—SARCA.

[6758].—**Measuring Brickwork.**—What is the custom in and around London when measuring for labour only and for labour and materials? Is it usual in the first case to make no deductions for openings, such as for doors and windows, and in the second case to deduct only half the openings? I have heard of it being done in the Eastern counties, but should like to know if it is correct and general.—M. A. J.

[6759].—**Notice to Quit.**—Will any subscriber answer me the following? About five weeks ago, wishing to leave my house I determined to give the landlord a month's notice, but he, not having given his address, I was obliged to wait until he called for the rent, which was not until the 11th of October, or eleven days later than usual. I then informed him of my intention of leaving, to which he agreed, and told me to try and let the house (also raised the rent). I did not succeed in doing so. At the end of the month I left the house, and wrote him to that effect, to which he replied that he required a month's notice from the 1st, thus claiming another month's rent. Am I legally bound to do so, or was not the notice I gave him, the raising the rent, and authorising me to try and find a tenant a sufficient acknowledgment of the notice being sufficient?—F. W. H.

REPLIES.

[6678].—**O-Traps.**—I notice in your issue of Sept. 13rd, amongst intercommunications under the above heading, a description of a trap given by "Inquirer," of which he seeks further particulars. The one he refers to was patented about 12 months ago; it possesses the essential points necessary for a good trap, and I fully endorse the opinion in respect to it expressed by "Practical" in your issue of Oct. 7th. I am intimately acquainted with Mr. Pullen's patent O trap; it is well made, and is a great improvement upon both the manner and form in which these traps were previously made. I also am thoroughly conversant with Mr. Davies' scale for making O traps, one of the great defects in the manufacture of these was the rule of thumb principle upon which they were generally constructed. The O-Interceptor, as "Inquirer" names it, might be described as having two chambers formed by the

diaphragm, which assists to make the seal, the one chamber being the size only of the dip-pipe and corresponding exactly to that half of the eclipse trap as shown Figs. 75 and 76 in the BUILDING NEWS for the week ending Sept. 16th. The other chamber is rather more than double the width, and has the channel of the trap carried right across it, the contents being emptied on both its sides. The channel is sometimes carried at one of the sides, the contents in that case running over the other side, the outlet being taken preferably in a straight line from the bottom of the trap. It is self-cleansing, and retains its water-seal, especially against waiving out by strong currents, however induced. The remarks in the latter part of "Practical's" communication, I think, were well timed, and I am strengthened in this opinion by Mr. Davies' rejoinder to Mr. Buchan in your paper for Oct. 28th. I do not think that he should have assumed such a tone, as it is apparent, even to those who do not know them (I happen to know both gentlemen well), that there is a latent interest in whatever either has written. I am expressing the opinions of several with whom I have conversed upon the matter, in regretting this exhibition of personal feeling, as there is no doubt great good will proceed from the opinions and experience of the several correspondents who have taken part in the controversy, especially from the able and practical articles written by Mr. Davies. At the same time one cannot help taking exception to the invidious references and comparisons that occur in respect to traps of his own design or make; for instance, he refers to the oval lip-trap, Fig. 97, as being similar to one of his, Fig. 95. Again, Sept. 30th, he advances the plea of its being all-sufficient to state that Pollen's new and improved \square trap is made after his seal; and again, in treating of ball-traps, after first describing those of his own design, I cannot help but express an opinion (not mine alone) that he has not done justice to the Bower-Trap, Fig. 102. He refers to the bottom piece C being made of glass militating much against the efficacy of the trap under certain conditions, which he gives. Now Mr. Davies must, or should know, that the depending cup C is more generally made of lead, and most certainly would not be recommended fitted with glass cup to be used under the conditions he names. There are at least two special features of this trap patented, and which cannot be infringed: (1st) The use of the floating ball as adapted in this case, and which he admits would be required in his No. 95 trap to make it equally as efficient. Can he adopt this part of the patent? He further proves the utility of the floating-ball by directing the overflow pipe to be taken into the inlet-pipe, because, however charged with sewer-gas the contents of the cup might be, the ball being securely seated against the dip or inlet-pipe, prevents the passage of any of these gases through the fixture; another advantage of the ball-seal is that the trap is not so liable to have its water-seal broken by evaporation. (2nd) The depending cup, when taken off, holding all the contents of the trap, is a desideratum in the case of the cup and screw. This could not be done, and very frequently it would be impossible to place a vessel underneath to catch it. I may say that I am not in any way interested in the Bower-Trap—rather otherwise.—J. W. HOLLAND.

[6385.]—Variation of the Compass.—Every now and then the subject of the variation of the compass is called attention to by some of the readers of the BUILDING NEWS, and, so far as I am aware, no entirely satisfactory solution of the problem has yet appeared in its columns. In this paper I shall explain three of the methods usually employed to find the variation, and I hope in such a manner as to be easily understood without much help from the science of physical astronomy. Some of our almanacs give the variation from year to year at Greenwich, which may serve the purpose of those who live near that place, but the variation not only varies from year to year, but is also different at different places at the same time, thus making the given Greenwich variation of little practical value to the community at large. The first method I shall notice is that of finding the true south from the sun; it may be stated in a rule thus:—Find the time when the sun will be due south, and observe its centre at that time. At Greenwich the sun is due south at 12 o'clock Greenwich time, on, say, four days every year, for all other days his southing at that place may be found by adding or subtracting the "equation of time" from 12 o'clock. The equation of time may be got from an almanac under some such heading as "clock fast," "clock slow," "clock before the sun," &c. The time of southing at Greenwich is next corrected for the longitude of the place where the observation is made. This correction is in proportion as 15 deg. is to the longitude, so is one hour to the correction, to be added when the longitude is west, and subtracted when it is east from Greenwich. Thus, at a place 7° 15' west longitude, the sun will be south at 29 minutes past 12, when the sun and the clock are together. The semidiameter of the sun should be noted previous to the observation, so that the edge of the sun's disc may be taken and the semidiameter added or subtracted to get the centre. The greatest objection to this method is the difficulty of getting Greenwich time in out-of-the-way places with sufficient accuracy for the purpose. Near places connected to Greenwich by telegraph the difficulty is not so great; but when it is considered that four seconds of time will cause an error of 9" in the result, even time sent by telegraph (unless with instruments specially constructed for the purpose), will be looked on with suspicion for this purpose. The error likely to occur from incorrect time in observing the sun is greatly diminished when a star near the North Pole is observed instead of the sun. Thus an error of four minutes in time would give an error of 1° if applied to the sun, but if applied to the Pole star the error from this cause could not exceed one minute. This proves that the second or stellar method, if carefully performed, is less likely to give any appreciable error than the first or solar method. This second rule is:—Find the time that any star at or near the North Pole will be north or south, and observe it at that time. The time when any star, the right ascension of which is known, is due south is found thus:—In most almanacs is a column headed "Sidereal time at noon" or "Sun's right ascension at noon." Subtract the time given in this column opposite at day of the month from the star's right ascension (if the star's right ascension be less than the sidereal time add 24 hours to it) and further diminish the result by 10 seconds for every hour of the result. This will give the time

from midnight that the star will be south at Greenwich. This must be corrected for longitude as in the first method, with the sun at the rate of one hour for every 15 deg. east or west, but no correction is required for the equation of time. The time when any star will be due north is 11h. 58min. after it is due south. The right ascension of the Pole star may be taken as 1h. 15min. 15sec., and its distance from the Pole 1° 19' 23". Both of these are subject to a slight variation from year to year, but for practical purposes this may be disregarded. From what has been stated, it will be seen that the Pole Star is 1° 19' 23" from the Pole when due east or west, and that it will be due east or west 5 hours 59min. before or after it is due south. This gives an opportunity for observing it at every six hours end. The sidereal time at noon can be approximately found thus:—At midnight between 21st and 22nd March in each year, it is 0 hours 0min. 0sec., and increases 3min. 56sec. every 24 hours, so that on coming to the same date the following year it will be 24 hours or 0 hours—then if 3min. 56sec. be multiplied by the number of days between March 21st and the date of observation and 1min. 28sec. added, it will give the sidereal time at noon for that date. The longitude of the place can be got from a large scale map. Both of these methods of finding the variation are open to the objection that they require the use of some data which may not always be accessible to the observer, such as the Greenwich mean time. But I will now give a plan of solving this problem, which does not require the use of any data whatever, a solution which is not affected by data, time, nor place on the earth's surface, but it is only practicable when any fixed star can be twice seen at an interval of 11 hours and 56 minutes from the same place, and, of course, can only be accomplished during the long winter nights, and when the evenings and mornings are clear. Select a star about the same height from the horizon as the Pole star, or the Pole star itself, find its azimuth bearing from the magnetic meridian (or any other fixed point), and note the time of observation. 11 hours 56 minutes afterwards repeat the observation on the same star, then half the difference in azimuth it has changed its position will be its distance from the northern meridian. This added or subtracted from its magnetic azimuth will give the variation of the compass. In the annexed diagram, let O be the place of the observer, O M

the magnetic meridian, P the North Pole, and at six o'clock let the star, S, be observed 25° east of M, the magnetic pole. At 5.56 next morning the same star is seen at S, 15° east of the magnetic pole; it having moved 10° in azimuth during the interval, will then be $\frac{10}{2} = 5^\circ$ from the true north; this added to 15° or subtracted from 25° gives the variation of the compass. Although I have advised a star near the Pole to be selected as less likely to be affected by refraction, the method may be applied to any star, and will give the variation exactly when the star is equidistant from the horizon at both observations; in other cases there is a slight error caused by the difference of atmospheric refraction. This error is so slight that it may be disregarded with impunity under ordinary circumstances, and the nearer the star is to the horizon it is the easier observed with the compass. A star's place in the heavens can be calculated when the star is invisible to the eye.—J. MCW.

[6712.]—Breaking Weight of Cast-Iron Stanchions.—"Inexperienced" omits one of the most important in his dimensions of stanchions, that is the height, for on this depends the question whether the column or stanchion will be broken by crushing or bending or both combined. For a height of five diameters and less it will have a tendency to break by crushing only, above eight diameters by crushing and bending combined, and above about sixty diameters by bending only. The height should not exceed twenty-five diameters. In a series of tables given in a paper read by Mr. R. Moreland, jun., M.I.C.E., at the Architectural Association on "Iron Construction," H stanchions of equal measurements each way bore a breaking load in tons per square inch, for 16 diameters high 2½, 20 diameters 17½, and 25 diameters 13½ tons. This may help "Inexperienced" in what he requires. The diameter would be the smallest dimension of section; in the case given by him, 5in., the safe load would be one-tenth of this. If both dimensions were equal one-sixth might be allowed. This paper can be found in BUILDING NEWS, Jan. 16, 1874. See my answer to No. 6560 on "Beating Loads" in BUILDING NEWS, July 22 of this year. I see no formula in Hurst applying to the case in point, but "Inexperienced" and others cannot expect anything easier for the purpose than the formulae given in that and similar works.—H. McLACHLAN.

[6713.]—Shoring.—What is generally required in shoring is to relieve the weight from some damaged portion of a wall that it may be repaired, to support the wall above when the lower portion is removed as in putting in a shop-front or a bay-window, to prevent a wall buckling or falling outwards, to stay the openings and sometimes to support the floors and roofs so that less weight may be thrown on the wall. "W. G. M." will learn most by studying shoring of buildings when in pro-

gress. He can read "A chapter on Posts and Shores," BUILDING NEWS, Aug. 24, 1877; "The Mechanics of Shoring," BUILDING NEWS, Sept. 14, 1877, and a paper by Mr. J. P. Seddon read at the Royal Institute of British Architects "On the Shoring of Grosvenor Church," reported in the BUILDING NEWS of Feb. 7, 1873. The best is to be found in M. V. Le Duc's "Dictionnaire de l'Architecture," on the word "Etai." It is well illustrated.—H. McLACHLAN.

[6715.]—Varnishing Exterior Woodwork.—In what way is paint "more or less a sham"? I have always considered a sham to be an imitation or pretence, and cannot see anything of a sham in a plain coat of paint, though it may become such when used in graining, marbling, &c. In my opinion for exterior woodwork there is nothing like a plain coat of oil-paint of a good colour which will not readily show dirt, for instance oak-brown or bronze-green; no one would ever take either of these to be imitations of oak or bronze. Also if light-coloured woods are varnished, it is necessary first to stain them, even though in a slight degree, and I consider this is far more of a sham than a coat of paint, as it makes a commoner description of wood to appear to be of a better kind. Varnish may be used if preferred and the objections made apply also to paint. Look at coach-builder's varnish on carriages and see how much more free from blistering it is than paint. Certainly this is of the best description, but I believe others of a cheaper description might be obtained to equal it. Ask the opinion of a manufacturer as to the most suitable kinds. Those made of the harder gums would be found to be less likely to blister and more durable than the others as far as I know. It should be remembered that paint for exterior work is never less than three coats thick, whilst varnish is generally not more than one, to obtain durable work more should be added. If superior woods are used, as oak, teak or pitch-pine, I should prefer varnish or dead polish, but if deal paint; pitch-pine is not very suitable for exterior work. Varnishing and painting should be left till September; it has then a longer time to harden before being exposed to the summer sun which causes the blistering whilst the work is soft. If left till later in the year, it is slow in drying, there being more moisture in the air.—H. McLACHLAN.

[6716.]—Examination Question, Roof.—"Student" will have to study construction more than he has done at present. The problem of compound iron and wood construction is a very common one, the ends of timber scantlings are received into cast-iron sockets or shoes with holes for the passage of the tie-rods, the latter being screwed up tight by means of nuts; when the main tie-rod runs horizontally across, like a tie-beam, it is flattened out in the centre and a hole made for the king-rod to pass through, the nut being fastened on beneath.

Fig. 1 is sketch of joint at foot of king-rod. The joint at head is similar. The proper way to determine the size of the different members is to find the strains on them, either by the graphic method referred to in other answers or by calculation. I have shown annexed a diagram Fig. 2, scale 16ft. to an inch; Fig. 3, 1in. to a ton, of the strains with roof worked out by the graphic method, and have supposed loads of 1 ton each acting at joints 3, 4, 7, 8 and 10, with reactions of 2½ tons each at 1 and 2. There are of course additional strains and reactions at 1 and 2, but as they act directly on the walls, may for the purpose under consideration be neglected. Compressible strains are represented by thick lines and tensile by thin. The strains in the several members are as follows:—A, compressible, about 6 tons; B, compressible, about 5½ tons; C, compressible, about 3½ tons; tie-rod between G and C, tensile, about 5½ tons; between G and C, about 4½ tons tensile; king-rod, tensile about 2 tons; tie between b and c, about 1 ton; strut between c and d, compressible, about 1½ tons, and strut between a and b about 1 ton. Whether the strain is compressible or tensile is shown by the triangle or polygon of forces for the joint under consideration, the arrow-heads following round all the sides in the same direction when the joint is in equilibrium, and since the direction of one of these must be known, the others will follow in due course; and if such triangle or polygon be supposed to be applied to the joint under consideration, those arrow-heads which point towards the joint would show that the pieces are under a compressible strain, and if from, under a tensile. I have numbered the joints as they should be taken in due course; first, No. 1, draw G A = 2½ tons on scale, parallel to wall with arrow-head

pointing upwards showing the reaction of the wall, from A draw Aa parallel to piece between A and a, and from G draw Gg parallel to tie-rod between G and g, meeting the last in a, G A a is the triangle of forces for joint 1; and since G A points upwards, A a points obliquely downwards towards the joint, the raft A a is therefore subject to a compressive strain, following in the same direction as the tie-rod from the joint showing the tie-rod is subject to a tensile strain. In the same manner with the other joints, finishing with joint 10, the polygon for which is C D E F G H I J K L M N O P Q R S T U V W X Y Z A, which is a closed polygon, and forms two triangles, Joint 9, I would mention is more regular, being G d e f, the line G being equal and over G d, acting in opposite directions and neutralising each other. The line A F represents the scale of external loads and reactions which of course neutralise each other. The lines representing the strains of the pieces in the external framing are drawn from this, and for the miter braces, &c., from the ends of the former to which they are adjacent. The diagram of strains is lettered so that the strains of the pieces represented therein lie between the same letters as in the diagram of the roof above; and all lines are drawn parallel to the pieces the strain of which they represent. It will also be noticed that each line in the lower diagram will be read twice and in opposite directions, showing it is in equilibrium. The line or part thereof is traversed eight times to represent the tie-rod, G a, G h, G i and G j. I cannot go further into this but if "Student" will study the books referred to in answer 6728 he will without doubt understand the whole. I give to finish the dimensions of pieces required:—Rafters 2in. by 11in. large struts 1in. by 3in., small struts 3in. by 2in., tie-rod 1in. diameter, king-rod 1in. diameter, remaining ties 1in. diameter. The question did not however require all this to be worked out, a rule of thumb answer evidently only was required. —HUGH MACLACHLAN.

[6733].—Asbestos.—If "A Subscriber" wishes to return a room, I should not recommend an asbestos fire. One was used where I was articulated; it had to give way to hot water, owing to the untold complaint of a working in the room. Mr. Trevor also in his answer owns that "the heat generated in insufficient to make a good draught in the flue." It certainly is cleanly, and in the appearance of a fire is only required, I know of nothing better for the purpose. There is usually more than three times the quantity of pumice-stone than asbestos used, it being as serviceable and much cheaper. —H. MACLACHLAN.

[6731].—Old Crosses in West Cornwall.—Mr. Henry Hens, in his interesting communication, does not really answer the inquiry for information, as I suppose, in reference to purpose and origin of Cornish crosses. I am not aware of anything having been written on the subject. This much is clear. There are three descriptions of crosses in Cornwall—namely, the tall churchyard and wayside crosses on steps, which in no way differ from others in various parts of England, and a third sort, which I have only seen in Cornwall. This is a short cross, about 5ft. high, with no step, with generally a rounded top, which is carved a Maltese cross. These abound. Their date, I think, is early 14th century. There are two theories as to their use. One is that they marked the boundary of ecclesiastical property. The other, which I think the correct one, is that they were guides to pilgrims visiting the holy wells. Two things must be remembered of Cornwall in the olden time. A great part of the country, it being hilly, was uncultivated and sparsely inhabited, consequently there would be few roads. The other, the partiality which the people showed for sacred wells and springs. Of course, in a hilly country there are a great number of these, and they so dominated in the impressionable minds of the Keltic as to be made objects of worship, which continued into Christian times, and was made useful by the priesthood. Now, when from some reason—a fictitious miracle, perhaps—a spring or well became famous, it was necessary over the open country to guide people to it, and this I think is the origin and use of the crosses referred to—guide marks. Some years ago, when visiting my friend Mr. Venning, and who, no doubt, would be glad to see Mr. Hens, he showed me in the neighbourhood of his house at St. Clether, about a dozen of these crosses, several of them being on his farm. In confirmation of the theory of being guide-posts, I found them without exception on the side of present roads, these roads, of course, being formed on the old tracks in more modern times, and they led to a ruined chapel built over a well on Mr. Venning's farm. The nearest two or three crosses appeared to be exceptions to the rule of marking a road, as road there was none. On my mentioning the matter, however, to my friend, he informed me that these crosses did really mark an old road, but that the road in modern times had been diverted for the convenience of his farm. Three miles from Luaneston, at Holywell, is one of these crosses with its well. —M.

[6732].—Dow-draught in Chimneys.—When a chimney acts as the air-conductor into a room, it shows that air inlets are wanted. Provide these by vertical pipes, sherringham ventilators or other openings and I believe that the majority of cases of dow-draught would be cured. Such a method does not of course prevent the wind blowing down the chimney or other little matters which cause chimneys to smoke. Chimneys should never act as fresh air inlets, though they may sometimes serve the purpose of foul-air outlets; proper ventilation also acts favourably on the health of those using the room. Improved stoves will cure smoky chimneys at times but the patent Manchester grate is only one of many. "W. B." can refer for further information to an answer of mine on "Smoky Chimneys" in August or the end of July last. —H. MACLACHLAN.

[6734].—Rain-Water.—I would advise "J. R." to have the tank examined. Possibly some mortar has been left in by the workmen engaged in building it, the lime when it dissolved by the rain water would account for the hardness. A tank-lime or chalk is easily acted on if any has been about got into the tank. Good cement would not be dissolved, but if any has broken away and the contents have been mixed up with common mortar, the water would reach it. —H. MACLACHLAN.

[6735].—Rain-Water Separator.—The invention which "B. S." inquires about is Buck's Patent Percolator, an apparatus for rejecting the bad and storing the pure water from a roof. It is self-acting, and prevents the first portion of the rainfall, which washes down the

impurities of the roof, from passing into the storage tank by directing the water into a waste pipe or separate tank for a time. Afterwards, when a certain quantity has passed through, the percolator vents over and turns the pure water into the storage tank. Having tested the apparatus thoroughly for two years, and finding the results most satisfactory, I have, within the last fortnight, purchased the patent, and have arranged for its manufacture at the Percolator Works, Hachinore, Surrey. —CHAS. GAY ROBERTS.

[6731].—Rain Water.—The machine referred to by "B. S." is very likely that known as a Buck's Patent Percolator. It was described in "The Gatherer" in *Cassell's Magazine* for January, 1880. I am not able to give the address, but perhaps the above will assist in finding more particulars. —A. R. F. TREV.

[6733].—Working and Detail Drawings.—There is a book on "Working Drawings and Practical Designs in Modern Building and Architecture," edited by R. Scott Burn, the price of which is £1 15s., and may be obtained at Mr. Batsford's, 52, High Holborn, W.C. There is also another book on "Drawings for Builders and Students," by George Payne, published by Crosby Lockwood and Co., price 7s. 6d., giving practical rules on drawings for the operative builder and young student in architecture. —FRED J. FREEMAN.

[6733].—Working and Detail Drawings.—The only works I know with working drawings are the series published by Messrs. Laxton some years ago, now difficult to obtain. The subject may be learned from Nicholson's works. Rolson's "Carpenter, Joiner, Mason, and Plasterer's Guide," both works out of print. Perhaps the best elementary treatise is "Journeyman Plasterer" can get it that published by Cassell and Co., and which appeared in the "Technical Educator." The series I mean were intended to instruct artificers in their trades, and, I believe, most of the trades are published at a very moderate price. —G. H. G.

[6740].—Concrete Houses.—With good cement and a suitable aggregate, concrete walls can be built one-fourth less in thickness than is needed if of brickwork, and with better results. To construct floors and staircases of concrete is necessarily more difficult than to build plain walls, and would require in respect for explanation than could possibly be permitted in the Intercommunication Column of the BUILDING NEWS. There are several patented methods and processes for floor construction; but in an ordinary way the latter can be easily accomplished with Portland cement and coke cinders, or brick debris, with a small amount of practical experience and at a moderate cost. As an instance of the extraordinary strength of concrete, I give one of a series of experiments made with concrete composed of one part of Portland cement and four parts of broken brick ballast gauged to an inch mesh, the concrete being well beaten in place, and covered with water for seven days. The size of floor was 17ft. 6in. by 16ft. 6in., the actual dimensions in clear of sustaining walls 14ft. 6in. by 13ft. 6in., and the thickness 6in. uniformly throughout. At the end of 21 days a party of 80 men marched on to it at quick time and double time, then jumped, but no fracture taking place, it was loaded with bricks till 10 tons was accumulated, when it broke suddenly without any warning. The result of this experiment will give your correspondent some idea of the thickness needed for his floors and the proportions of his materials. Concrete made from any calcined material will withstand heat as well or better than ordinary bricks, but for flues the circular fire-day flue-pipes are certainly preferable.

For party floors there is a patented glue made by Eberhard and Co., 8, Edward-street, Hampstead-road, which is, I believe, very efficacious in causing the wood to adhere to the concrete. Wood bricks can be built in the walls for fixing the joinery thereto, but the concrete fixing bricks made by Mr. Lascelles, of Bunhill-row, are far preferable for that purpose. The cost of concrete depends largely upon circumstances, but may be said to range from one-half to three-fourths or more that of brickwork. For further information on each of these points see "Concrete, its Use in Building," published by Spott and Co.—THOMAS POTTER.

[6740].—Concrete Houses, having concrete floors, stairs and roofs (as well as walls) have been built in considerable numbers during fourteen years past, and some are now in course of erection by the undersigned, who will have much pleasure in showing them and in giving fullest information upon all the points mentioned in the question. As to give anything like a complete reply would occupy much more space than the usual limits of "Intercommunication," and could not be so complete as verbal information, combined with ocular demonstration. I shall be glad to give the latter if "Dulce et Decorum" will communicate with me. —CHARLES DRAKE, Railway Wharf, Battersea Park.

[6740].—Concrete Houses.—Let "Dulce et Decorum" apply to any of the concrete manufacturers and builders advertised in the BUILDING NEWS, who will furnish him with every particular. There is no reason why the floors and staircases should not be built of concrete, the former require iron joints at intervals and we can recommend the Bennett's stem. Stairs of concrete, 3in. to 4in. thick, have been laid on light iron joists or wooden joists. Staircases are constructed every day of this material, and there is no material that surpasses it for strength, durability, or fireproof qualities. Walls of ordinary houses may be about a third thicker than those of brickwork. The stairs are best cast and put together like stone ones. Concrete stands into heat well. Wood blocks or wedges are necessary for fixing. —G. H. G.

[6743].—Liability of Yearly Tenant.—There is no implied covenant on the part of the tenant that he will put building in repair. There ought to have been an agreement to make repairs compulsory on the tenant, if such was intended. But even when there is no agreement I believe a tenant can be made to keep the fences in repair. The tenant of rural lands is supposed to use the buildings in a tenant-like manner, and I turn in a husband like manner. —G. H. G.

[6741].—Measuring Hay-Ricks.—Consult any work on measurement of solids, such as Baker's treatise, Lockwood and Co.'s or Nesbit's "Measurement." The rules for measuring are precisely the same as those for calculating the contents of solids. Circular ricks have to be measured in two parts—1st, for the frustum of cone or

the lower part of rick, and 2nd, the cone or roof. Square or rectangular ricks are measured as follows:—The lower part is taken as a prismoid, and the upper as a triangular prism, the rules for which may be found in any book on mathematics. —G. H. G.

[6741].—Measuring Hay-Ricks.—The best method of measuring hay-stacks is to take the length of side half way between ground and eaves from out to out, and allow from 6in. to 6in., according as the exterior presents either a neat or loose appearance. Then take the opposite side adding the two together and dividing by 2 to get the average; proceed, the same with the ends. The height is taken about one third way up the roof, either at the ends or side by putting the tape on a rod or stick. Measure to ground and allow 6in. for steddle or the debris on which the rick rests. To ascertain the cubical contents, find the number of feet per truss, say, 6ft. to 7ft. close, 7ft. to 8ft. medium, and 8ft. to 9ft. loose. Multiply the average of sides and ends together, and that by the height. Divide that total by the number of feet per truss, according as you think the stack either close or coarse, and that remainder by 36 to bring it to loads, and 40 to bring it to tons. —T. WILLIAMS, Farnham.

[6741].—Measuring Hay-Ricks.—In reply to "Karyaka," I beg to offer some hints on the measurement and weight of above. The weight of a hay stack varies with the density of hay, from 1 to 2 cwt. per cubic yard. A rick of hay seldom weighs above 5 stones (of 22lb. avoirdupois each) per cubic yard. A hay-stack of a moderate size, when newly made, may, in ordinary cases, weigh about 6 stones, and after it has stood for some time, about 7 stones per cubic yard. A large stack may weigh about 8 stones, and, when the hay is old, about 9 or 10 stones per cubic yard. The weight of any hay-stack may be estimated pretty accurately as follows:—Cut out from that part of the stack where you judge the hay to be of a medium density, a part from the top to the bottom, extending to the centre of the stack, and, having weighed it, say, as the content of the vacancy, to the content of the whole stack, so is the weight of the part cut out to the weight of the stack. Thus, for example, if from a hay stack which measures 350 cubic yards, a piece measuring 12 cubic yards being cut out, is found to weigh 18cwt. 14lb., the weight of the stack may be estimated to be about 25 tons 18cwt. for 12 : 350 :: 18cwt. 14lb. : 25 tons 18cwt. 3qrs. 12lb. No. 1. To measure a hay-stack when the body resembles a cylinder, add one-third of the perpendicular height of the top above the horizontal section, passing through the eaves, in feet, to the height from the ground to the eaves, in feet, for the mean height, which multiply continually by the square of the girt in feet, and by .00294; then will the last product be the content of the rick in cubic yards. Example:—How many cubic yards and stones of hay are there in a rick which measures 18ft. from the ground to the eaves, 9ft. above the eaves, and 5ft. in circumference, allowing 7 stns of 22lb. avoirdupois each to the cubic yard! $(18 + 3) \times 57 \times 22 \times .00294 = 201.1$ cubic yards $201.1 \times 7 = 1407.7$ stones. No. 2. When the body of the stack resembles a conic frustum, add together the square of the girt at the bottom in feet, the square of the girt at the eaves in feet, and the product of these two girts. Multiply the sum by the perpendicular height of the eaves from the ground in feet. To the product add that of the square of the girt at the eaves, multiplied by the perpendicular height of the top above the horizontal section passing through the eaves. Then multiply the sum by .00294; and the product will be the content of the stack in cubic yards. Example:—How many cubic yards are there in a hay-stack of which the perpendicular height from the ground to the eaves measures 11ft., the perpendicular height of the top above the horizontal section passing through the eaves 10ft., the girt at the bottom 33ft., and at the eaves 60ft. ?

$$\frac{(33^2 + 60^2 + 60 \times 33) \times 11}{60^2 \times 10} = 73350$$

$$\frac{(18 + 3) \times 57 \times 22 \times .00294}{109350} = 201.1$$

$$\times .00294 = 107.41 \text{ cubic yards.}$$

—FRED J. FREEMAN.

CHIPS.

A branch lending library of the South London free library and art gallery was opened at the Horns Institute, Bermondsey-square, on Tuesday, by a fine art exhibition.

The partnership between Messrs. Whitmore and Kennard, architects and surveyors, of Devonshire-square, Bishopsgate-street, E.C., has been dissolved.

The corner-stone of the first villa in Walton Naze Park, East Essex, was laid on Monday by Lady Johnson, of St. Osyth Priory. The estate has been acquired from Sir John H. Johnson on a 999 years lease, by Mr. Philip Breanor, architect, of London, who proposes, in consultation with Dr. B. W. Richardson, to form "a true Hygeiaopolis." The villas will be built on the cliff summit, and will be Gothic and Swiss, and the undercliff is to be laid out as gardens, and made accessible by winding roads and stairs. The scheme also includes as future operations, the formation of docks in Walton creek, a railway line connecting with the Great Eastern Railway system both at Walton and Harwich, and the reclamation of waste land to the north of the estate.

Zion Baptist Chapel in Adelaide-square, Windsor, was opened on Tuesday week. Built of white brick, it is furnished with moveable seats for 100 persons; Mr. E. Knapp was the contractor.

The river Wear Commissioners, at their meeting on Wednesday week, decided to build a new north pier at the entrance to Sunderland Harbour, in accordance with a report made by Sir John Coode, C.E. The estimated cost is £145,000.

LEGAL INTELLIGENCE.

BREACH OF BY-LAWS.—At Hammersmith last week Joseph Stapleton, a builder, of Devonshire-road, Chiswick, and James Baker, appeared to answer summonses for disobeying the by-laws of the Improvement Commissioners of that parish. Mr. Poland, instructed by Mr. Finnis, clerk to the Commissioners, appeared to support the summonses; Mr. Grain for the defendant Stapleton. It appeared that the defendant Baker occupied a house in a row which had been built by Stapleton and a partner in Chiswick-fields-lane in accordance with plans allowed by the Commissioners, leaving an open space of 200 square feet behind each, as required by the bye-laws. After the occupation of the house by Baker alterations were made by the erection of a bakehouse and oven at the rear without the consent in writing of the Commissioners, thus reducing the area of the open space. Mr. Poland said it was an important matter to the parish, as it affected all the open spaces of the houses which had been erected by the defendant Stapleton. The object of the proceedings was to obtain the judgment of the Court so that it might be known that the by-laws must be observed. Mr. Grain argued that his client was not liable, as the lease had passed out of his hands. Mr. De Rutzen, after hearing witnesses, said it was clear that both defendants had taken a share in building on the open space without the consent of the Commissioners. It was important that it should be nipped in the bud, for, if additions were allowed, in time the whole would be built over. He fined each of the defendants 10s., with three guineas costs in one case, and 1s. and 2s. costs in another. Mr. Finnis then proceeded with a third summons against the defendant Stapleton for building on another part of the estate without notice to the Commissioners or depositing plans. Mr. Grain admitted that an error had been committed, but said his client was quite willing to comply with the regulations. Mr. Finnis said the Commissioners had no desire to press the case unduly, but he hoped in future that the defendant would take care not to infringe the by-laws. Mr. De Rutzen said it was important that the notices should be given, and fined him 40s. and 2s. costs.

SURVEYOR'S CLAIM ON A CONTRACTOR.—At the Court of Record, Scarborough, before the Borough Recorder and a jury, the case of Baker v. Jowsey was heard on Tuesday and Wednesday week. Plaintiff, James Baker, carries on business in Scarborough and Parliament-street, Westminster, and defendant, William Jowsey, is a contractor at Scarborough. The action was for £127 4s. 10d., for work done, services rendered, and money paid at defendant's request, and defendant paid £20 into court to satisfy the claim. For the plaintiff it was stated that he was called in by defendant to settle a dispute with the South Cliff Tramway Company in respect to the amount due under a contract, when plaintiff rendered efficient services and was paid £90. Afterwards the defendant contracted with the Seamer School Board for the erection of schools there, and had only proceeded with the work a short time when he became involved in disputes with the board. He again applied to Mr. Baker to assist, and 59 letters passed between the parties between February 14th and September 10th of the present year. Plaintiff eventually came down and saw Mr. Woodall, the clerk of the Seamer School Board, and Mr. Carrall, their architect, on several occasions, and endeavoured to effect a settlement. Plaintiff had charged three guineas per day for his services, third-class railway-fare, and 7s. per day hotel expenses, and of the total claim £127 4s. 10d. was disputed. Plaintiff's counsel added that it was known to defendant that plaintiff had got into difficulty with his private affairs, and defendant no doubt thought that if he refused to pay, plaintiff would not dare to come into court and have certain affairs inquired into. Plaintiff was examined in support of his claim, and said that the usual charge was by commission, if over a certain sum, but below that the surveyors charged five guineas per day. Mr. Carrall, architect to the Seamer School Board, said, when the dispute occurred as to extra work, defendant introduced plaintiff to him as his surveyor, and the latter endeavoured to arrange the dispute. Defendant, however, was not open to reason of any sort, although witness offered to make considerable sacrifice out of his own pocket. He considered three guineas per day not an excessive, but a fair, charge. In cross-examination he said he believed he spent altogether about seven hours with plaintiff and defendant discussing the matter. Mr. Woodall, clerk to the Seamer School Board, corroborated as to plaintiff's services, and said it was owing to his action that the board consented to knock off the £1 a day penalties, which they were entitled to under the contract. For the defence it was contended that the sum charged was a monstrous charge for the services rendered, and would be amply met by £20, as the final settlement was made without Mr. Baker's assistance. Mr. J. Barry, Scarborough, said £20 was sufficient for the work done. The measurement could be

done in a day. Mr. W. Peacock said it was ridiculous that anybody should occupy 15 days for a little job like that at Seamer; he would not pay three guineas a day to a surveyor. Mr. D. Petch, architect, Scarborough, also thought the charge excessive. The jury returned a verdict for £35, in addition to the £20 paid into court, and the costs were ordered to follow the verdict.

CITY COMPENSATION CASE.—(Lord Mayor's Court.—Before the Recorder and a special jury.)—A claim was made on behalf of Mr. Wayland to recover compensation against the Metropolitan and Metropolitan District Railway Companies in respect of certain property in Eastcheap, of which he was the freeholder, and which was required by them under the compulsory powers of their Act of Parliament for the completion of the Inner Circle Railway. On the part of the claimant, the value of the property was variously estimated by Mr. Castle (Messrs. Fuller and Horsey), Mr. Chatfield Clarke and Mr. Price (Ellis and Co.), at from £16,000 to £16,500. On the part of the defendants, Mr. Alderman Ellis (Lord Mayor elect), Mr. George Trist (Watney and Trist), and Mr. Farmer (Debenham, Tewson, and Farmer), valued it at under £10,000. The case lasted nearly two days, and ultimately the jury found for the claimant for £12,975.

RAILWAY COMPENSATION CASE.—(Middlesex Sheriff's Court.—Before Mr. Under-Sheriff Burchell and a Special Jury.—Greenville and Woodbridge v. the Hounslow and Metropolitan Railway Company.)—This was a remarkable railway compensation case. Between three and four acres of land was required for the new railway being constructed at Hounslow, and the claim was about £7,000, and the surveyors who were examined for the claimants considered the land was fit for "building purposes." On the part of the company the claim was termed "exaggerated," as the utmost value was estimated at between £1,500 and £1,600. The case occupied the whole of Wednesday, and had been adjourned from August, when only a few jurymen attended, and it was postponed until this week on account of the "insufficient number of jurymen." On behalf of the company it was alleged that it was 20 years "in advance of the time" to term it "building land." In the course of the case Mr. W. G. Harrison, Q.C. (with Mr. Dugdale), who appeared for the claimants, said that lawyers disagreed and doctors differed, but of all men "surveyors disagreed." Mr. Grantham, Q.C., with Mr. Wright, represented the company. The learned Under-Sheriff left the jury to decide on the conflicting evidence of the surveyors, and after a brief consultation gave a verdict for £4,000.

MOSSE V. KILLICK.—This was a peculiar case. The plaintiff, a clergyman, who is patron and former incumbent of the valuable benefice of Great Smeaton, in Yorkshire, in the year 1879 presented the defendant to that living. The rectory house was at that time temporarily tenanted by a Major Godman; the plaintiff claimed a certain amount of rent payable by the tenant of the rectory-house, and brought an action therefor in the Court of Queen's Bench, in which he failed. There was a further charge for fixtures, which it had been agreed should be taken by valuation. Included, was an item for a conservatory of peculiar construction, which the defendant contended was not a fixture; it was attached to the freehold, and even then a useless incumbrance. The defendant also set up a claim, on demurrer, for use and occupation of glebe by the plaintiff for certain of his brood stock of horses, together with some stacks of hay, the plaintiff alleging in reply that he had rented the pasturage of the then occupying tenant, and had duly paid his demands. The case was sent down to Mr. Ralph Nicholson, of Westminster, diocesan surveyor for Ripon, as a special referee, to try the case. Mr. R. O. Lane, barrister, represented the plaintiff, and Mr. Gainsford Bruce, barrister, the defendant, at the trial. A curious point turned upon the straying of the plaintiff's horses, in consequence of the fences being broken down by the South Durham Hunt. It being deemed advisable that the referee should view, an adjournment for that purpose was made.

UNHEALTHY SCHOOLS.—At Wandsworth on Wednesday, a summons was heard against the occupier of the Boys' School at Roehampton in respect of a nuisance on the premises. Mr. Radford, the surveyor under the Board of Works, said the drainage of the school was in a very bad state. It was not only dangerous to the inmates, but it was a nuisance to persons who passed the schools. The schoolmaster, who appeared to answer the summons, said there had been scarlet fever in the school, causing it to be closed for six weeks. There was a scare in the neighbourhood, and many of the families left, so that the subscriptions ceased, and the committee could not meet. The school was open again, and he thought they would be able to proceed with the work. They were quite anxious to get rid of the nuisance as the Board Mr. Corsellis, the clerk of the Board, suggested that scarlet fever broke out at the school in con-

sequence of the state of the premises. The schoolmaster said the disease broke out, not in the school, but outside. An order was made as prayed, the work to be completed in a month.

WATER SUPPLY AND SANITARY MATTERS.

ASHFORD, KENT.—On Wednesday week, Mr. Samuel J. Smith, C.E., inspector of the Local Government Board, held an inquiry at Ashford, Kent, with reference to an application from the local board for leave to borrow £15,000 for the purchase and enlargement of the waterworks; £16,000 for the contemplated intercepting sewer and works of sewage disposal; and £300 for road repairs. As to the waterworks, a copy of the award was put in, stipulating that the board should pay to the water company the sum of £10,311, and also £411 8s. 6d., the arbitrators' fees. The inspector commented on the smallness of the pipes in some of the side streets, remarking that the Local Government Board would not sanction such pipes now. The surveyor to the local board exhibited plans of proposed additions to the works, including a new reservoir to hold 115,000 gallons, new rising main, duplicate engines and pump, the whole estimated to cost about £4,000. In regard to the sewage-works, Mr. Mansergh, C.E., gave explanations, showing that the estimated cost was £13,370, and £2,000 for a new sewage system to South Ashford. The inspector said the system of sewage treatment in operation at Canterbury would not be permitted at Ashford, and the board must decide on some chemical process before the sanction of the Local Government Board would be given. He mentioned the process adopted at Tong, near Bolton, as being reported to be very successful. Mr. Mansergh advised the Coventry system.

SOUTHAM, WARWICKSHIRE.—On the 21st ult. the sewage disposal works were handed over to the sanitary authority. The works comprise the laying of a main outfall sewer, from tanks to new outfall grounds, and the preparation of the same for the reception and purification of the sewage. The purification works consist of three and a half acres of land situate about one mile from Southam, and formed into six level beds. The ground was dug over to the depth of 3ft. 6in., underneath which is placed a foot of sand and gravel, having drains, sewage distributing carriers and chambers, and roads. The system adopted is intermittent filtration. The rural sanitary authority only a few years ago carried out at Southam a system of sewage and screening through so-called filters in tanks in duplicate, the result of which proved a total failure, and terminated in action being taken by the riparian proprietors below the town. In the scheme of filtration now adopted, the existing tanks in duplicate, which are situated near the town, are utilised to arrest the solids and road detritus, which deposit will be removed periodically by means of a four-inch diameter chain-pump, and will be dug into the ground adjacent to the tanks. The distance from the tanks to the sewage farm is about a mile, a nine-inch main having been laid at a gradient of 1 in 600. The normal flow of sewage is estimated at 75,000 gallons every 24 hours, with a capacity for 565,000 gallons in case of storm, and outlet into the river in case of necessity. By opening the disc-valves the sewage can be applied to any one or the whole of the six beds at the same time, and would be capable of successfully dealing with upwards of half a million gallons per day. The cost of the works, inclusive of purchase of land, has been about £2500. Mr. Edward Pritchard, C.E., F.G.S., of Westminster and Birmingham, was the engineer-in-chief; Mr. Charles Law Green, C.E., the resident engineer, and Mr. Alfred Palmer, of Birmingham, the contractor.

THE DRAINAGE OF TWICKENHAM.—The Local Board of Twickenham having applied to the Local Government Board for sanction to borrow an additional sum of £10,000 for works of sewage, Major Hector Tulloch, R.E., one of the inspectors of the latter authority, has just held a public inquiry into the subject matter of such application. About £70,000 has already been expended in the drainage of the town, which, it was stated, is so near completion that no further loan beyond that now asked for would be required. The precipitation and filtration scheme in progress is that of the town surveyor, Mr. H. M. Ramsay. It was understood that Major Tulloch would recommend the sanction of the Local Government Board to the proposed loan.

The parish-church of Thurston, Norfolk, was reopened last week after restoration, including rebuilding of north wall and the re-laying of the entire roof with new thatch. The work has been carried out by Mr. John Fowler, of Seething.

An exhibition of Scandinavian art is to be held next year at South Kensington.

STAINED GLASS.

ST. LEONARD'S.—The east window of St. John's Church, St. Leonard-on-Sea, has recently been filled with stained glass. The subject represented is the Crucifixion, with Mary Magdalene kneeling at the Cross; on either side are standing figures of St. John and the Blessed Virgin Mary and St. Peter and St. Paul. Under each of the figures are subjects relative to the life of St. John (after whom the church is named). There are angels at the top of each light looking towards the figure on the Cross. In the tracing is the Dove and the Alpha and Omega. The window was designed and executed by Messrs. Heaton, Butler, and Bayne, of London.

SWINDON.—Two memorial windows have just been placed in Swindon Church, Wiltshire. The larger of the two is a two-light and tracery window, with the subject of the Call of Nathaniel, carried through the two lights, with floriated ornament surrounding the same, and a similar style of ornament in the two bases, with an inscription at bottom of window (same ornament carried through tracery). The other is a two-light and tracery window, with the subject of Christ healing at the Pool of Bethesda, carried through the two lights, with perpendicular canopy above, and baselined in a similar manner. In the largest piece of tracery is the bust of St. Luke as the Good Physician.

CARDIFF.—Four of the windows, facing Working-street, in the reference department of the new Free Public Library, have been filled with stained glass at the cost of Mr. J. Ware. The glass has been carried out from the designs of the architects of the building, Messrs. James, Seward and Thomas, of Cardiff, by Messrs. W. B. Simpson and Co., of St. Martin's-lane, London, W.C., and the subjects are:—1, Poetry, represented by a portrait of Milton; 2, History, represented by Gibralt; 3, Travel, represented by Raleigh; 4, Fiction, represented by Scott. The whole of the figure work has been drawn by Mr. F. Weeks, and the lead lines are gilded. Four other windows of stained glass have been promised for the entrance corridor of the building.

STATUES, MEMORIALS, &c.

THE YORKTOWN MONUMENT.—The *American Architect* gives an illustration of the design for the Yorktown monument, prepared by a commission appointed by the Secretary of War under an Act of Congress. The commission was composed of Messrs. R. M. Hunt and Henry Van Brunt, architects, and J. Q. A. Ward, sculptor. It is the design accepted by the joint Congressional Committee. It will be constructed in one material throughout. The preference of the commission is in favour of Ellettsville limestone. The Act of Congress, following the original resolution of one hundred years ago, specifies "a marble column"; and in accordance with the evident intention of Congress, the commissioners, in the design, have confined themselves to Classic precedents. The monument is composed of three principal parts. The first is a base, which, with its stylobate and its pediments, is 37ft. high, and occupies an area 30ft. square upon the ground. The second is a highly sculptured podium, 25ft. high and 13ft. in diameter, in the form of a drum supporting a column. The latter, which is part third, is 60ft. high, and at the base somewhat more than 7ft. in diameter. This shaft, for the sake of economy, is composed of a succession of drums or courses of masonry, giving practical reasons for a departure from the conventional treatment which belongs to monolithic shafts. The joints are partly masked by four bands, decorated with laurel leaves, and justified for a decoration of stars symmetrically disposed upon them and breaking the outline of the column. From the symbolical point of view, the monument is intended to convey, in architectural language, the idea set forth in the dedicatory inscription that by the victory at Yorktown the independency of the United States of America was achieved or brought to final accomplishment. The four sides of the base contain, first, an inscription dedicating the monument as a memorial of the victory; second, an inscription giving a succinct narrative of the siege, prepared in accordance with the original archives in the Department of State; third, the treaty of alliance with the King of France, and fourth, the treaty of peace with the King of England. In the pediments, over these four sides, respectively, are presented, carved in relief, emblems of nationality, of war, of the alliance, and of peace. The base is thus devoted to the historical statement. It explains the subsequent incidents of the monumental composition, which are intended to appeal solely to the imagination. The immediate result of the historical events written upon the base was the happy establishment of a national Union of thirteen youthful, free and independent States. To celebrate this joyful

Union, the sculptor has represented upon the circular pedium which arises from the base, a solemn dance of thirteen typical female figures, hand in hand, encircling a drum, which bear upon a belt beneath their feet the words, "One country, one constitution, one destiny." It is a symbol of the birth of freedom. The column above, surmounted by a figure of Liberty, may be accepted as typifying the triumphant results of a century of freedom, in the harmonious union of thirty-eight independent States, each of which is marked by a star upon the shaft. In the midst of this constellation appears the shield of Yorktown covering a branch of olive. The model has been exhibited at Yorktown during the recent celebration.

CHIPS.

The paving and lighting committee of the Ipswich town council have recommended that body to raise the salary of Mr. E. Buckham, the borough surveyor, by £75 a year.

The prizes and certificates gained by the students in the Colchester Science and Art Classes were distributed on Monday evening. The report showed that, in art, out of 63 examined 50 were failures, 11 obtained ordinary passes, and two only were marked excellent. In the Science department, out of 109 examined, nine prizes and 56 certificates were obtained. Complaint was made at the meeting that, although the members had increased, the attendances of students were very irregular.

The town-council of Weymouth opened on Wednesday week three sets of competitive designs sent in, for the improvement of the King's Statue, and decided to exhibit them for one week at the Guildhall, before deciding the award of the premium.

At the annual meeting of the St. Nicholas, Newbury, Stained Glass Window Society, it was stated that it was proposed in future to aim at raising about £115 annually, to provide one new stained glass window each year in the parish church. On the motion of Mr. W. Money, F.S.A., it was resolved to erect a window as a memorial to John Winchouse, better known as "Jack o' Newbury," to whose munificence the building of a great part of the church was due.

The local board of Heston and Isleworth decided by the narrow majority of 7 votes to 6 to provide the surveyor, Mr. Bromley, with a horse and vehicle, or in lieu of that, to raise his salary from £200 to £300. Mr. Bromley was appointed six months since.

The general purposes committee of Cardiff rejected on Monday an offer made by the Marquis of Bute of a site on which to erect a commodious central market, and instructed the borough surveyor to prepare plans for altering the present building.

At the meeting of the Darlaston sanitary authority on Wednesday, it was reported that five persons had been attacked with blood poisoning, one of whom had succumbed, in consequence of drinking water highly contaminated with sewage matter. It was stated that water taken from certain wells had caused 15 deaths from scarlet fever in Darlaston during the past four weeks. It was decided to close the wells and obtain wholesome water for the people.

A new Wesleyan chapel and schoolroom was opened at Baraby, near Beccles, on the 27th ult. The building is Italian in its architecture; constructed externally of red and white brick and stone. It is found that the acoustics of the building are excellent. The work has been carried out by Messrs. Dunn and Cutler, builders, of Beccles, from the designs and under the superintendence of Mr. Edgar Goff, architect, of Lowestoft. The cost has been about £450.

The tower of St. Peter's Church, Ipswich, which has been reported unsafe by Mr. J. O. Scott, is to be levelled to the belfry floor and rebuilt therefrom.

St. Peter's Church, Vere-street, Oxford-street, having been seated in oak, with carved pulpit, &c., and decorated from the designs and under the superintendence of Mr. James K. Colling, will be reopened on Sunday next.

The New Spa hydropathic establishment, Bishops Down, Tunbridge Wells, was reopened on Tuesday week after the addition of a wing from plans by Mr. Benjamin Taberner, of London. Messrs. Wilcombe and Oakley, of Tunbridge, were the contractors.

An entertainment to workmen and their wives was given at Holloway College, Egham, on the 19th ult. by Mr. Thompson, Mayor of Peterborough, the contractor for the building, in commemoration of the opening for service of a large mission-room attached to the college. The room had been decorated, and a stage erected, under the superintendence of Mrs. Crossland, wife of the architect.

Our Office Table.

At the meeting of the Metropolitan Board of Works on Friday last the Works Committee, to whom the subject of a site for a new fish-market for London had been referred, presented their report, recommending the Board to approve of a site at Blackfriars, as well as application to Parliament next session for power to acquire that site. The Chairman of the Committee moved the adoption of this report. An amendment was proposed in favour of the site at King's Cross; but this was rejected, and the recommendation of the Committee was lost by a majority of one.

The Viennese Society of Artists propose to open in April next, in their Galleries at Vienna, an exhibition of the chief works of art, native and foreign, which have been produced since the last Great Exhibition of 1873. It will comprise works of architecture, sculpture, painting, drawing, and die-sinking, as well as those of the various arts of reproduction. It is patronised by the Austrian Government, which is to give prize medals to exhibitors under the award of a jury.

A MEETING of the Midland Association of Gas Managers was held at the Grand Hotel, Birmingham, on Thursday week, under the presidency of Mr. Peter-on, of Cheltenham. There was a good attendance of members from different towns in the Midlands, and discussions took place on the "distribution" of gas, and on the standard water-horse. Mr. J. Tindall (Walsall), who contributed a paper on the former subject, urged the desirability of a more effective distribution of gas in street mains, and of regulating the pressure by governors at the works. He held that the district supplied should be divided into two or three levels, as the case might require, supplying each level separately. Even where a district was level the distribution would be better effected by divided systems of supply. The advantage Mr. Tindall claimed for his plan was that it would enable them to equalise pressure as nearly as possible at the consumers' meters, and reduce leakage to a minimum. The subject was discussed at some length.

GRAVESEND, principally associated in the minds of Londoners with tea and shrimps, may after all have a more noble part to play in the future commercial history of England. For years past there has been an increasing disposition to make use of Gravesend as the place of embarkation and debarkation for the port of London. Some of the immense steamships of the National Company, which used always to start for New York from Liverpool, now set out from Gravesend. The Peninsular and Oriental ships prefer Gravesend to Southampton. The docks which are to be constructed on the opposite shore will occupy one of the finest natural positions for docks to be found in the kingdom, the Tilbury Marshes lying for the most part below high-water mark. It is by no means unlikely that Gravesend may become what its sanguine inhabitants at present certainly contemplate—another Liverpool and the true port of London.

The following caustic note by "Live and Let Live" appeared in Tuesday's issue of the *Western Mail*, anent the Pontardulais Market and Public Hall competition:—"The extravagance of the directors of the Pontardulais Market Hall Company is really most reprehensible. They actually propose laying out £5 5s. in the purchase of plans for their new hall. As no architect with any brains or taste is likely to be caught by such munificence, it stands to reason—especially as a footnote to the advertisement shows that an architect is not wanted, but only a lot of plans, to be manipulated at pleasure—that the directors ought to have applied to one of the Swansea or Llanelly builders, who would gladly have made a plan good enough for them for nothing."

An excellent room for exhibiting the pictures and other works of art which are offered as prizes in connection with the Art Union on behalf of the Manchester School of Art, has been secured in the Victoria-buildings, St. Mary's Gate, Manchester. The exhibition was opened to the public on Tuesday, free of charge, and, apart from the particular object in view, the collection is well worth a visit. The whole of

the works have been received as donations from artists, local art dealers, and London publishers, and their aggregate value is estimated at about £6,000. The School of Art will, it is hoped, be largely benefitted by this effort of its friends, and the public who have purchased, or intend purchasing, shares in the Art Union, will have the gratification of knowing that the prizes are of substantial value. The etchings and engravings—all artist's proofs—comprise works by S. Consins, R.A., Legros, Rajon, Seymour, and others. The chief prize is a painting by Calderon, "The Queen of the Tournament," worth 800 guineas. Other prizes are selected from the works of J. C. Horsley, R.A., A. Grimshaw, T. S. Cooper, R.A., and others. The paintings and drawings alone number about 200. The Art Union drawing will take place on the 19th December.

This is the state of things described as existing in a fever-den at Chesterfield:—Two small rooms, indescribably filthy. A sleeping-room, unventilated, 10ft. across each way, the air so vitiated that it was almost impossible for a sick person to recover in it. Four children in one bed, one of them dying of scarlet fever; five persons on a mattress on the floor. The "condition of the room horrible, and the stench fearful." Eighty-three cubic feet of air for each member of the family who slept in that room, whereas a common lodging-house is compelled to allow 300 cubic feet per person, and a sick person ought to have 850 cubic feet of air. These are the bald facts brought out at the inquest, and in the face of them the jury appended to their verdict a mild request that the Corporation should make a thorough investigation into overcrowding in the borough.

AN endeavour is being made, in connection with the forthcoming Health Congress and Domestic Exhibition next month at Brighton, to bring together for exhibition a thoroughly illustrative collection of architectural and decorative designs as complete and as representative as possible. The idea is a good one, but the efforts of those engaged in the enterprise will surely be seriously hindered, in securing the desired end, by the singular terms of the circular issued to the profession by the general committee. These rates for payment, both for superficial wall space and floor frontage, may be all very well for the exhibition of manufacturers' specialities and productions. Few architects or artists, however, will agree to such terms; while those of good repute and ability are hardly likely, on any terms, to allow their designs to be shown in an exhibition where space can be secured by any tyro for the payment of a few shillings where to exhibit, probably in the most prominent position thus paid for, works devoid of any merit at all. The exhibition may be an important one, and its arrangements may be exceedingly comprehensive; but it would be by better far to exclude all such contributions as above referred to, than in the end only have a show of miserable examples, no matter how well the space thus occupied may have been paid for.

It is pretty well known that the water-fittings of many parts of London are very inferior in quality, ancient in pattern, and in most indifferent repair. It is not so well known that some of the Water Companies of the Metropolis have long possessed powers enabling them to insist upon improved fittings. They have, indeed, remarks *The Ironmonger*, regulations providing for the thorough overhauling of all such appliances, but as they themselves have been backward as regards constant supply, they have been conveniently blind to the deficiencies of their customers' appliances. In this way one fault has led to the perpetuation and multiplication of others, thereby storing up, both for the companies and their "tenants," an infinity of trouble and aggregated expense. Examples of this trouble have recently been forthcoming in that portion of South London which is supplied by the Lambeth Waterworks Company. That company is now engaged in efforts intended to reduce waste, and to bring the fittings nearer to a reasonable standard of perfection than they have been hitherto. The preliminary visits of inspection have shown that the waste of water from defective closets, cocks, pipes, &c., is very large. Notices of the usual kind have been served accordingly, and have excited strong opposition on the owners of property. The tenants have suffered from the supplies having been cut off in many instances, but if they are

wise they will cheerfully second the efforts of the company, seeing that they will thereby obtain fittings of a proper description.

AFTER much delay, the Great Western Railway Company have set about the construction of a loop line to Weston-super-Mare. The new loop-line will be four and a half miles in length, and proceeding from the Bristol side it is meant to diverge from the trunk railway about a mile and a half south of the present Worle Station, joining the main line again nearly a mile and a half south of the Weston Junction, thus cutting off about three miles of the main railway, and, for through trains, adding a mile to the length in going round, compared with the distance at present traversed. The drawings and specifications for the works have been prepared by Mr. Francis Fox, C.E., Bristol, and the directors of the company are prepared to receive tenders for the construction of the line. It is intended to proceed with the undertaking as speedily as possible.

MR. SLAGO, M.P., and the other Royal Commissioners on Technical Education, who have been on the Continent for the last fortnight, have been visiting various science schools in the different centres of Italy. Proceeding to Milan, the Commissioners visited the Exhibition of National Products. They next inspected the special school at Como, where instruction is given in the weaving and dyeing of silk. Thence they went to Biella, the centre of a prosperous trade in woollen and cotton goods. On Tuesday night the Commissioners returned Paris, where they will be joined by Mr. Samuelson, M.P., and will forthwith enter upon an investigation of the trade schools in Paris.

CHIPS.

Works of sewerage have just been completed at Hulton for the Lanesdale rural sanitary authority. Mr. Walker, surveyor to the board, superintended the work, which has been carried out by Messrs. Brigg and Lancaster.

Last week the foundation-stone of new public baths for Wigan was laid. The architect of the new buildings is Mr. George Heaton, of Wigan, who was awarded the first prize in the contest for designs; and the builder, Mr. William Winnard, of Wigan.

A public clock, presented to the borough of Maldon by Mr. George Courtauld, M.P., was inaugurated on Thursday week. It is a dial-clock projecting on brackets from the town-hall front; it is provided with automatic lighting apparatus and a chime of five bells, for striking the Westminster chimes at the quarters. Messrs. Gillett, Bland and Co., of Croydon, carried out the work, including the erection of a turret in which the bells are housed, at a cost of about £400.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers. Discussion on A. T. Walmisley's paper on "Iron Roofs," 7.30 p.m.

Royal Institute of British Architects. Opening address by the President, G. E. Street, R.A. 8 p.m.

Surveyors' Institution. Opening address by the President, E. Ryde. 8 p.m.

TUESDAY.—Institution of Civil Engineers. "Iron Permanent Way." By Chas. Wood, M.I.C.E. 8 p.m.

WEDNESDAY.—Society of Arts. Opening address by Sir F. J. Bramwell, F.R.S., Chairman of Council. 8 p.m.

FRIDAY.—Architectural Association. Address by the President, Aston Webb. 7.30 p.m.

Trade News.

WAGES MOVEMENT.

APPREHENDED STRIKE IN THE EARTHENWARE TRADE.—If the men strike at Martinmas, the 11th inst., for increased wages, as threatened, the trade in the Staffordshire Potteries will be almost at a standstill. The masters, it is said, are almost unanimous in their decision to withstand it. The men at the recent disputes agreed to go before arbitration, and they had the benefit of two distinct arbitrators, Lord Hatherton and Sir T. Brassey, M.P., who decided against the men. After a comparatively short interval, the men appear to have come to the conclusion to throw over this award.

Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Only in Packets labelled—"JAMES EPPS AND CO., Homoeopathic Chemists, London."—Mak 2rs of Epps's Chocolate Essence for afternoon use.

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, BILIOUSNESS, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. *See Medical Testimony.*

Holloway's Pills and Ointment.—Precious Remedies.—Cramps, vomiting and griping, quickly yield to their potent properties; the deathlike sickness passes away, and the glow of health returns as the riction of the Ointment causes the irritated nerves to become soothed and calmed. In local inflammation they act like a charm.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to **CHARLES TRASK,** Norton-sub-Hamdon, Ilminster, Somerset. —[Advt.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates.

General Repairs and Alterations Executed: Experienced Workmen always in readiness, and sent to any part of the country.—[Advt.]

BATH STONE.
BOX GROUND,
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.
(See trade advt. on p. XXIII.) Advt.

TENDERS.

* * * Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ABERDEEN.—For mason, joiner, slater, and plumber's work required in the erection of a mechanics' and carpenter's shop in the Harbour Yard, Provost Blaikie's Quay, Aberdeen. Mr. W. Smith, Aberdeen, resident engineer:—

Mason's work:—	
Farquharson, W.	£285 0 0
Grant, T., Aberdeen	267 10 0
Grieg and Craib, Aberdeen ...	245 0 0
Smith, L., Aberdeen	243 0 0
Smith & Beattie, Aberdeen (accepted)	232 10 0

Joiner's work:—	
Coutts, G., Aberdeen	129 0 0
Dinnes and Middleton, Aberdeen	119 0 0
Grant, J., Aberdeen	109 0 0
Frith and Tolmie, Aberdeen ...	107 0 0
Farquhar, J., Aberdeen	106 0 0
Skinner and Hall, Aberdeen ...	105 0 0
Alexander, D., Aberdeen	101 0 0
Smith, F. M., Aberdeen	98 10 0
Scott, J., Aberdeen	97 10 0
Jamieson, G., Woodside	97 0 0
Gordon, W., Aberdeen	86 0 0
Johnson and Fullerton, Woodside*	84 0 0

Plumber's work:—	
Blaikie, J. and Sons	9 7 6
Bruce, C., Aberdeen	7 16 6
Robertson, A. and Son, Aberdeen...	5 5 0
Thom and Strachan, Aberdeen*	4 7 0

*Accepted.

Slater's work:—No offerers.

ABERDEEN.—For supplying and fitting up a boiler for the steam tug alarm at the Girdness, Aberdeen Harbour. Mr. W. Smith, harbour engineer:—

Blaikie Bros., Aberdeen	£159 0 0

Hudson, W. E. (accepted)	£19 4 10
--------------------------	----------

Hackney, E.—For repairs to the roofs of the workhouse and infirmary of the Hackney Union:—

Workhouse.	Infirmary.
Barker	£73 0 0
Blow	53 0 0
Williams & Abigail	75 0 0
Burnan and Sons	53 0 0
	112 0 0

*Accepted.

Halifax.—For erection of a hospital at Stoney Royd, Halifax. Quantities by Mr. E. R. S. Escott, borough engineer:—

Parker, Halifax	£1,497 0 0
Green, Halifax	1,471 0 0
Culpan and Son, Halifax	1,379 0 0
Illingworth Brothers, Bradford	1,280 0 0
Foster and Yates, Halifax	1,276 0 0
Bolton and Co., Halifax	1,213 0 0
Sutcliffe and Woodhead, Halifax	1,180 0 0
Firth and Son, Queensbury	1,069 0 0
Dyson and Son, Halifax	1,059 0 0
H-Jford, Halifax	1,041 0 0
Walker, Halifax	1,034 0 0
Hopkinson and Son, Halifax	1,030 0 0
Naylor, Halifax	1,021 0 0
Gaines, Halifax	1,013 0 0
Brook, Halifax	1,003 0 0
Drake and Riley, Halifax	991 0 0
Fearnley and Firth, Halifax	978 0 0
Wilson & Son, Halifax (accepted)	955 0 0

(Engineer's estimate, £1,030.)

Hawley, Hants.—For additions to All Saints' Home and completing chapel, Hawley. Mr. A. H. Hoole, architect:—

Goddard and Son	£1,785 0 0
-----------------	------------

Hawley, Hants.—For erecting stables to the Manor Farmhouse, Hawley. Mr. Arnold H. Hoole, architect:—

Goddard and Son	£394 0 0
-----------------	----------

Hildersham.—For erection of temperance hotel at Hildersham, for Mr. G. D. Webster. Mr. J. Earnshaw, Brighthelm Quay, architect:—

Mason's work:—

Owston (accepted)	£560 0 0
Rennard	550 0 0
Walkington	540 0 0

Joiner's work:—

Clark	410 0 0
Mainpriz	400 0 0
Leeson	365 0 0
Bailey (accepted)	310 0 0

Kensington.—For new offices on forecourt No. 260, Kensington Park-road, S.E., for Messrs. Biant and Son. Messrs. Muggeridge and Powell, architects:—

Riddell	£435 0 0
Fisher	397 0 0
Burman	380 0 0
Taylor	387 0 0

Knowbury.—For the erection of a mission room at Knowbury, Shropshire. Mr. E. Turner, Bowing Green-street, Leicester, architect:—

Howell, W., Tenbury	£960 0 0
Hine, J., Ludlow (accepted)	875 0 0

Lanark.—For the erection of a new chapel at Smillum Orphanage, Lanark. Messrs. Pugin and Pugin, Westminster, architects. Quantities by Mr. R. O. Harris, Queen Victoria-street:—

Accepted tenders.

Excavator, mason, and bricklayer:—

McMorian, E., Carstairs Junction	£951 0 0
----------------------------------	----------

Carpenter, joiner, and ironmonger:—

Baxter, J., Glasgow	688 9 11
---------------------	----------

Slater and plasterer:—

Glaister, T., Lanark	238 4 7
----------------------	---------

Plumber, painter, and glazier:—

Proctor and Son, Biggar	145 0 0
-------------------------	---------

Total

	£2,005 11 6
--	-------------

Lancing, Sussex.—For additions and alterations to The Warren, for Mr. E. Solz. Mr. Frederick W. Hyde, architect:—

Blaker, R. C., Worthing (accepted)	£550 0 0
------------------------------------	----------

For general repairs, painting, &c., to The Warren:—

Sandall, W., Brighton (accepted)	£110 0 0
----------------------------------	----------

Liverpool.—For the supply of fittings for the water engineer's department, for the town council:—

Robson, G. (accepted)	£48 0 0
-----------------------	---------

Liverpool.—For the supply of steel castings, for the town council:—

Souther and Southern (accepted)	£1,512 10 0
---------------------------------	-------------

(Fifty tons at £29 per ton; extra work, £62 10s.)

Liverpool.—For vestibule doors at the Walker Art Gallery, for the town council:—

Firth, H. (accepted)	£108 4 0
----------------------	----------

Llanabescolen School Board, near Carnarvon.—For new school and master's residence, to be built at Bethel, near Carnarvon. Mr. O. M. Roberts, Portmadoc, architect:—

Pritchard, O. and W., Llanfair	£1,680 0 0
Jones, E., Dolydd Greslon	1,660 0 0
Morris, O. O., Greslon	1,540 0 0
Owen, R. R., Greslon	1,500 0 0
Jones, E., & Owen, D. Bangor	1,488 0 0
Griffiths, W., Waelawr	1,440 0 0
Owen, W., & Edwards, H. Caethro	1,430 0 0
Williams, J., Goeite Treborth	1,395 0 0
Williams, G., Penryn	1,375 0 0
Jones, R., Tyddyn	1,356 0 0
Williams, D., Carnarvon	1,318 0

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 11, 1881.

MR. STREET ON BAD BUILDING.

AS might have been expected, Mr. Street, in his able opening address at the Institute on Monday, dealt largely with the artistic duties and responsibilities of the profession. For the first time during a long series of presidential addresses, we have heard art placed first and spoken of as the real object of the Royal Institute of British Architects, and, notwithstanding Mr. Street's denial of the existence of the selfishness which it has been alleged has sometimes characterised the proceedings of the corporation over which he now presides, it may be reasonably doubted by outside critics whether the Institute has on all occasions been distinguished by magnanimity, or even by such activity as it has recently shown in the furtherance of one or two useful reforms.

One of the most instructive topics of the address was the apt comparison made by the speaker between the vernacular architecture of the present day and that of the last century. It was justifiable to inquire, how it is that with the ever-increasing body of architects, of education and training, the buildings erected by 19th-century builders are so inferior to those built in 1750? The question may certainly be fairly put to a body which represents, as it is contended, the architecture of the country, and, as Mr. Street owned, architects cannot quite escape the responsibility. We venture to put another question, the legitimate answer to which will, we think, show that the responsibility for the bad building which now exists mainly rests with the profession. Why is it the public prefer to have bad or inferior buildings rather than employ architects? With regard to the taste of the 19th-century builder, which, as Mr. Street very justly said, is to do everything for display and to waste money on ornaments to the "show-fronts" of the house, may it not be fairly argued, as by Mr. J. P. Sedden in the *Times* of yesterday, that this taste has been fostered by architects themselves? Has not the mania for sham Italian and Gothic facades, costly ornamentation in stucco and stone, to be laid largely to our own doors, and are architects entirely innocent of the "show-front?" We are very pleased to find that the new president has plainly hinted to architects the extent to which they share in the responsibility for creating a taste for ornament, and we hope that the remark will be taken to heart as it deserves to be, and not be lost. The matter is certainly of sufficient importance, for it may be asked whether much improvement is likely to take place till the builders, bricklayers, and carpenters of our houses are set the example by architects. We have, on so many occasions, spoken of the duty of architects to show that good plans and sound economical and simple construction lie at the root of all artistic building and good ornamentation, that it is gratifying to find so eminent an architect as the president saying that "our duty is to show by example that simple building may be quite as good as extravagant, and that the essence of all good architecture is that it should be solid and lasting before it tries to be ornamental." Another vice of the modern system is, we think, that want of solidity to which the speaker referred, though we venture to remark that the vice is not exclusively the builder's. It springs viciously but naturally out of the desire on the part

of the public to possess cheap and showy houses which shall compete with costly and elaborate designs, and among the results are the unfortunate examples too often before us of competition designs executed with the determination to obtain a semblance of all that is attractive with the least possible expenditure. The President did not go farther than point to these weaknesses; he might have shown that the lack of solidity in modern buildings was largely attributable to the pernicious taste for expensive ornamentation, and that the contract and the percentage systems of payment have led to both the evils, as we lately endeavoured to point out.

The necessity for a Government department for art naturally arose out of a consideration of the subject of bad building, but the President only lightly touched upon that part of the subject. We have always contended that in matters of taste the less there is in the shape of official interference or control the better, and this view is supported by the evidence of those who are the best able to form an opinion of the operations carried on by the Academy of Fine Arts in France, and the governmental control exercised over architects in Germany and other Continental states. Mr. Street referred to the subject in his address, though the views he expressed are hardly reconcilable with each other. In one part we were told, in allusion to the request made by the Metropolitan Board of Works to the Council of the Institute to exercise control over the designs of buildings in Northumberland-avenue, that "the position was a dangerous one, 'for, however good the taste of individual members may be, there is an unwillingness on the part of a body of men to criticise too severely the work of a brother architect.'" Every one will be disposed to agree with the truth of this opinion, and, to think with Mr. Street that if the Institute has no more power than it has at present, that it would be better, or at least quite as well, if it had less. Later on, however, the President, in speaking of the arrangement of routes for new streets and sites for public buildings, remarked that it would be advantageous if the subject were laid before the Council of the Institute, so that it might offer advice and opinion. In such matters, in defining positions and laying down lines of streets, the Institute might certainly be consulted with advantage, and probably hideous iron railway bridges, such as those which now disfigure the Thames, might in future be avoided. But did not the Institute express its anger when the Ludgate-hill bridge was contemplated, and with what effect? We have all the monstrosities we possess in the shape of structures, in spite of the Institute and, as regards questions of design, any attempt to control elevations would be a signal failure, as the results pointed to bear ample testimony. More irreconcilable with the previously expressed view of the President is the idea of the necessity of the creation of a Government Department of the Fine Arts. It is a very difficult thing to impose rules on architectural designs—they cannot be made conformable to the opinions of critics of various proclivities and tastes; but it is quite another matter to regulate building operations, and we join most heartily in the President's hope that before long the consolidation of the Building Acts of the whole country will be effected on a reasonable foundation.

BUILDING AT THE WEST-END.

CONTINUING our recent notes of new buildings at the West-end, we remark a few signs of activity in Victoria-street, Westminster. For a number of years, this rather busy thoroughfare seemed to have suffered from the mania for huge dwellings,

in flats and maisonnettes, and the neighbourhood, as a residential part, was threatened by an invasion of offices on a scale of palatial grandeur, built in stone or stucco. There has lately been a renewal of this rage for model town-residences, notwithstanding the failure of some of the undertakings, for we find no less than three or four important buildings of this class have lately been erected. The experiment of providing dwellings for the middle classes on the system followed by our French neighbours, has at least encouraged several to embark in speculations of this kind, and the heavy ground-rents of land in this locality have induced lessees to cover the frontages to the best advantage. Near the Grosvenor Mansions, and at the corner of Alexandra-street, is a large stone-fronted Late Gothic building remaining in carcase; a board outside informing the public that it is for sale. It is several stories in height, and has a corner turret or bay; the windows are mullioned, and the front is relieved by bays. The chief features of the architecture are the high, steep, double-sloped roof, the hipped dormers over the bays by which two or three tiers of attics are obtained in the roof. The fact of such a costly pile of "flats" not having been finished seems to throw a doubt on the success of similar speculations which are being made in the same street, and to suggest the question whether such large blocks of residences on this system can prove remunerative to the owners. A large adjoining plot of corporation land is vacant, to be let on lease for 80 years, and next to this is another extensive block of mansions, in red brick and cement, which has just been finished, entitled "Queen's Mansions." Architecturally, the building cannot be regarded as anything more than a speculative builder's work. The façade presents a monotonous series of windows and balconies with corner oriels and bay windows at intervals; no roof is visible, and the only relief is the additional height of a story at the ends and centre. The building is of five and six stories, besides the ground-story. Entering one of the sets on the ground-floor we find a spacious hall, lighted mainly by stained-glass windows from side areas, which are left between the chief blocks. A dining-room, about 30ft. long and of proportionate width, lighted in front, and three good bedrooms, bath-room, and offices are on this floor, with rooms for servants in the basement. The other floors furnish similar accommodation, and are approached by a wide staircase with spacious landings. Each residence is quite independent; there is a lift for service, gas is provided on staircases and landings, and each tenant has a brick wine and coal-cellar in the basement. The rents, which include all rates, taxes, and water, and the use of hall porter, vary on the chief floors, from £320 for the ground-floor to £260 for the second floor for the first year, and there is a small increase of rent for the second and third years. The balconies, of which there are three tiers in front, are useful additions, and add to the convenience and comfort of the upper floors.

A colossal and, in many respects, remarkable building, is in course of completion a little higher up. It is intended for the "Army and Navy Hotel," and its position is perhaps unique for such a purpose. The architect, we believe, Mr. Pilkington, of Edinburgh, has introduced a bold semi-Greek treatment, a style which has found admirers in the Northern metropolis, and which has been vigorously used by the late Mr. Alexander Thompson, and his school of Classicists. In London we have few buildings that represent the characteristics of this version of Renaissance. The most noticeable thing about the new hotel is the largeness of scale of the details; these have a monolithic size and appearance, admirably

suggestive of the unlimited stone resources of the North. The rounded angles of the façade are built of large blocks of a warm-coloured sandstone, from Northumberland, with moulded channels or rustications, and the ground and first stories are distinguished by a liberal use of the same material, above which the structure is chiefly of red brick of a deep colour. There is a large and lofty arched entrance in the centre, supported by Ionic columns of sandstone, and side bay windows, with rounded corners, crowned by massive entablatures, in which a deep coving is introduced beneath the cymatium and corona. The centre of the façade above the entrance is also marked by stone pilasters and entablatures to the windows; and the top story has a bold cornice and cove of stone, which is carried down in the form of wide architraves to the upper story of windows. Conventional ornaments of bold voluted design are carved at the heads of the architraves under the cornice, and vigorous foliage, with volutes, appears beneath the bay windows, and enriches the stone corbelling. We may mention that the return sides of the façade are not square, but are at a considerable angle, the effect of which makes the flank on the west side, adjoining an open space, a conspicuous elevation. Here the architect has connected the two lower tiers of windows by massive architraves which are carried up and finished by deep Greek cornices and pediments, crowned by acroteria or antefixæ. The heads of the lower windows have tympana, which are probably intended to be carved. The building is too unfinished to enable us to judge of the interior; there is apparently a large coffee or reading-room on the flank side, to judge from the proportions, and iron and concrete have been used in the flooring.

Brick and terra-cotta dressings have been largely used in this locality: for instance, nearly opposite, in a style much less grand and colossal in its details, is St. Margaret's House, a building in which red brick and light terra-cotta have been combined with some effect. The style is Renaissance; there is an arched entrance which leads to an open lobby and staircase, and the pilasters carrying the arch are panelled, and have emblematic figure-subjects of the Virtues introduced. A balcony over is carried by bold terra-cotta trusses. The façade is relieved by brick pilasters, and bay-windows enriched by dressings of terra-cotta, and the transoms and treatment of the entrances and windows are worth notice for the manner in which the latter material has been applied. The building we allude to is occupied by the National Penny Bank and other offices, and the floors above are devoted to chambers. Near, on the opposite side, is a large block of maisonnettes, suits of rooms and offices, the materials being red brick and cement, but designed in a very commonplace type of Classic; close to which red brick and terra-cotta have been well used in the Imperial Bank, a new building nearly completed, from the designs of Mr. R. W. Edis, whose drawing we hope to reproduce shortly. The building has two frontages; the main façade has two lofty bay-windows of four stories above which the front is gabled. The style is a kind of English Renaissance, sensibly treated, and plain; slight brick piers emphasise the angles of the bays, and the gables are broken by brick pilasters between the lights. But the main feature is the entrance and ground-story to the bank. Here red terra-cotta of a deep red colour has been used in a porch with pediment between the bays, supported by Ionic columns, while pilasters, partially fluted, of the same order, mark the angles of the bays. The spandrels, frieze, and other dressings are all of the material, and the execution of the work, and the cast ornamentation of triglyphs, drapery in spandrels, &c.,

are creditable. The brickwork above is pointed in black mortar, and the colour of terra-cotta harmonises satisfactorily with it. On the opposite side of the street is a large block of residences and offices in a more thoroughly Queen Anne spirit. It is built of red brick; the roof is of steep pitch, with two tiers of dormers, and a small tower or bay projects from the corner. The chief features in the elevation are pilasters in the upper stories corbelled from the face of the wall. The lower windows have pediments and stone dressings, and the general design partakes of Mr. Norman Shaw's style. We have no space here to notice other buildings. It is sufficient to say that this street of mansions is still active in brick-and-mortar; and there is one marked characteristic of the new architecture which distinguishes it from the old. The older façades are of stucco or stone, and are generally designed in a stereotyped Classic. If we care to note the difference between the Grosvenor Mansions, for instance and those of recent construction, it will be observed in the style of the architecture and the materials employed. The former are of stucco built in a costly Renaissance style, in which the entrances are made large and important features. These and the windows are introduced within arched openings—a style common in Paris. The upper stories are adorned by pilasters and panels of ornament. London smoke has made these lofty rows of mansions wear a dingy aspect, and many of them have been turned into offices. The new buildings are almost entirely constructed of red brick and stone; at least red brick enters largely into the façades, and palatial dignity of scale has not been the chief concern. Albeit its dingy appearance, Victoria-street may be compared to a new Paris boulevard. Its very straightness and the repetition of its features lack all the picturesque elements of the olden streets. What it will become when all its vacant spaces are filled up is conjectural; but it is quite possible that something may yet be done to relieve it of that painful formality and quasi-palatial grandeur it has at present.

THE BUILDING TRADES IN AMERICA.

It is a matter, not only of interest, but of considerable importance, to note occasionally the course of industrial affairs in other countries, and particularly of a continent like America, where labour questions attain such magnitude, and where so many of the conditions under which trade is carried on are similar to those of our country. Such an inquiry is especially useful at the present time, as it appears that throughout the United States a very decided revival of business has taken place, and there is more activity and briskness being shown everywhere than has been the case for some years past. The demand for labour is universally good, wages are fair, with an upward tendency, and nearly all classes are fully employed. We will first of all devote our attention to New York, and to a report lately issued by Mr. Hice, one of the chief authorities at the Census Office, containing a summary of the manufacturing industries of that city, exclusive of the great staple industries, such as textiles, the iron and steel trades, glass making, railway, shops, &c.; in fact, that class of manufactures which the French call *la grande industrie*. The list given by Mr. Hice is too long to quote *in extenso*, for it contains no less than 76 trades, in which are engaged 11,068 establishments, with an invested capital of 157,581,749dols., or about £30,516,319. The material used cost 267,012,236dols. (£53,403,415), and the product was valued at 435,422,102dols. (£87,084,420). The greatest number of hands employed at any

one time was 262,459, of whom 133,995 were males about the age of 16 years, 63,482 were females over 15 years, and 1,373 were children. The total amount paid in wages during the Census year was 89,513,931 (£17,902,786). A short epitome of those trades which have most to do with building will be of interest.

Industry.	Capital.	Material used.	Product.
Carpentering	\$1,725,682	\$3,438,871	\$7,051,328
Lumber, planed	\$83,197	1,152,860	2,202,919
Machinery	3,643,313	2,265,117	5,977,076
Marble and stonework	2,253,388	2,181,783	5,618,669
Masonry, brick and stone	604,000	1,060,433	2,103,744
Paints and materials	4,462,370	2,938,857	6,967,939
Plumbing and gasfitting	961,858	1,867,228	3,807,848
Upholstery	919,787	1,926,312	2,976,524
House furnishing goods	10,750	9,191	23,743
Furniture	4,333,683	4,204,602	8,605,779

The building trades indeed in New York State appear to be in an exceptionally prosperous condition, and the work now in progress in the city alone will represent an expenditure of 25,000,000 (£5,000,000). The most noteworthy feature is in the business buildings, which are remarkable for height and costliness of decoration. Indeed, ground is becoming so valuable in New York, that it is hard to say where the highest of buildings (which cost nothing extra in the shape of taxation) will eventually stop, the average elevation of the new streets in the city being ten stories. In the suburbs, too, there is just as much activity as in the city, the demand for residences for business men being unprecedented, and this is just as much in New Jersey as in New York. Throughout the whole of New York State, mechanics are thoroughly well employed, there being scarcely a town or village where some new school, church, hotel or factory, is not in progress. In consequence of all this healthy briskness, wages in the building trades have greatly gone up of late years, and especially during the last three years. Bricklayers, who in 1878 earned from 12dols. to 15dols. a week, now get from 18dols. to 24dols. (72s. to 96s.), and are in some places agitating for 27dols., and while some special class of workmen have increased their earnings 50 per cent., there is scarcely any branch which has not risen at least 25 per cent. Labourers, porters, and others of this kind, have increased from 30 to 40; and it may be safely said that there is not necessarily a single man out of employment in New York at the present time, whereas the unemployed three years ago were numbered by thousands. The following table of some of the most ordinary trades shows the rate of weekly wages and hours of labour in the two years 1878 and 1881 respectively:—

Trade.	Hours.	1878. Wages.	Hours.	1881. Wages.
Bricklayers	59	\$12 to 15	59	\$18 to 21
Masons	58	12 „ 13	59	15 „ 21
Carpenters and Joiners	50	9 „ 12	59	12 „ 18
Plasterers	50	10 „ 15	50	15 „ 21
Painters	58	10 „ 15	51	15 „ 18
Plumbers	50	12 „ 18	51	18 „ 21
Gasfitters	60	10 „ 14	59	15 „ 21
Slaters	50	10 „ 15	50	15 „ 21
Blacksmiths	60	10 „ 14	60	12 „ 21
Cabinet Makers	60	9 „ 13	60	15 „ 18
Coopers	60	12 „ 10	59	9 „ 15
Coppersmiths	60	12 „ 15	60	12 „ 15
Millwrights	60	10 „ 15	60	15 „ 21
Labourers	60	6 „ 9	60	9 „ 15

As far as the building trades are concerned, the average wages of the principal Eastern cities are about 2.50dols. a day for carpenters, a little over 3dols. for masons, and 2.50dols. for painters. Boston pays less than New York and Philadelphia, where rent, provisions, and general expenses are on a greater scale than in other towns. In the Western States, we find the same rule applying to the biggest cities, such as St. Louis and Chicago, where carpenters are getting 3dols., masons 3.50dols., and painters 2.50dols. a day. One would have thought that as the trade rolled westward, wages in the extensive and sparsely populated states would have been much lower; but in point of fact, it is just

the reverse, owing to the mining element, which has come into play and put all skilled labour at an abnormal figure. In Colorado, for instance, carpenters and painters get 3.25dols. a day; masons 4.25dols.; while in Arizona and New Mexico they can earn still more. It is not until we reach the Pacific section and find in California and San Francisco the competitive effects of large industrial towns, that wages of the building and other rates assume a more reasonable aspect, while employment is more difficult to obtain. The following table of building wages in the various states and cities may be of considerable interest for the purpose of comparison with wages in our own country, and to serve as a guide for those who are thinking of trying their fortunes in the New World.

States and Cities.	Carpenters. Per day.	Masons.	Painters.
EASTERN STATES:—			
Boston	\$2.50	\$3	\$2.50
Maine	1.75 to 2	2 to 2.75	1.75 to 2.25
Connecticut	1.75 „ 2	2 „ 2.75	1.75 „ 2.25
New Hampshire	a trifle higher.		
Vermont

STONEHENGE.—III.

WE have already given a plan and a section of Stonehenge, as it, in all probability, originally was when first built, and can but regret the little there is available to guide to any more clear and certain idea of the special circumstances and conditions under which this old-world structure was put together, and the stones of it brought into place. It is well worth further research, now so much needed; for could we but for a brief moment imagine the special circumstances of that so distant time, we should all the better be able to comprehend the motives which led to such building. First, as to its date. It is somewhat curious to look through an ordinary chronological list of the great events in human history, and at the various ways by which they have been noted—e.g., that of the famous Olympiads, originating as they did (and the fact is sufficiently curious) from the Olympic Games which took place every fifth year. This would seem to have been the most ancient and world-famous mode of computing time. It dates from B.C. 776. Then there is the era of the foundation of Rome, about—for the authorities are not quite agreed—753 B.C. Then there is the Christian era, now in such universal use over all Europe, at least, and Northern America, with a number of others, most of them recorded by years. But, in the days in which Stonehenge was built, or the stones of it brought together, we get, it would seem to be certain, quite beyond all this, and find ourselves literally in the very dimness and darkness of the past itself. Olympiads and years avail us not, and the historian of human events has nothing to tell us. He can but speculate about it, and thus go backwards till his sure dates quite fail him. It is curious to note here in passing how all this is narrowing itself, for the antique Hebrew history is getting to be

quite near, comparatively, and within visible ken. In this Stonehenge puzzle we can but leave the *historian* and look to the *geologist* for help and information, or at least speculation and useful conjecture. Indeed, the longer we look at this strange monument, of a long past state of things human, the more and more uncertain do we get, and the more necessary is it to go again and again to the *monument itself* for information, and to the yet visible remains of it, and to map these out correctly with all their yet remaining surroundings, at present too little thought about. We refer to the *embankment* and ditch surrounding the stone circles. Stukeley's plan would seem to be fairly given, as he saw things; but we hope shortly to be able to give a *plan of Stonehenge* as it veritally now is.

It would be perhaps difficult to say what first there is most strange about this strange monument; but we are inclined to think it must be the fact of the very materials of which it is composed, and the *where* they came from. The outer inner circle of stones, and the inner "apse" stones, it has been thought, may have been brought from Wales or Cornwall, or from the Channel Islands, and it is certain that this would not have been done but under the influence of very powerful motives—probably religious motives—since the stone to be found in the immediate neighbourhood would have answered to the full, if but the mere building of this stone circle had been all that was aimed at, or had there been nought but mere utility to provide for. This may to many seem but a slight matter, but can anyone imagine in these days of utilitarianism and matter of plain fact, anyone, or any company, travelling to a far-off country for the mere materials for a new church, or other structure? If Stonehenge was erected, as has been thought, at two distinct eras, the inner "boreshoe," as it has been termed, and inner circle of small stones—foreign stone—probably, says Mr. Stephens, formed the first and earlier temple. These may, he thinks, have even been built up elsewhere, at some even more distant date, and from thence brought over to Salisbury plain and set up there. An invading and conquering people, he thinks, may have brought over these weighty blocks of stone, hallowed to them, and then to add to their impressiveness repeated in the building up of the new work the same idea on a larger scale, and making use of the stone, found on the spot or near it, for the purpose. And he cites the fact of the "Kaaba," in Mecca, as a modern example of an ancient shrine, inclosed in a later, and larger, and more impressive and imposing structure. This may, indeed, have been so, though it takes from the sense of unity of idea we have of Stonehenge, as a whole, and as the embodiment of a simple idea from a single source. And it destroys also the supposed fact of Stonehenge being an insular thought embodied in stone. It makes of it a *Continental* thought. Looking at the plan of Stonehenge, as on page 519, it would seem to have not a little to support it; but turning to the section on page 420, we seem to have before us a single and complete idea, mysterious enough may be, but all built up at one time, and all for a unity of purpose, little as we may see of it, or into the meaning of it. We fear to speculate, and can but hope for further research and "digging," and inquiry on the spot, by those, too, that are careful and competent for the work. Might we not urge here that before anything a careful survey of this monument should be made, and thus to get, at the least, a correct *Plan of Stonehenge* as it now is?

We should not have ventured, interesting as the subject is, to dwell so long upon it, save to suggest that not only should every possible care of the ruins of Stonehenge be

taken, but that some idea of the nature of such rude structures be afforded to the London public. Might there not be, we would ask, casts taken of one at least of the *trilithons* yet standing, of two or four of the stones of the outer circle, and of one or two of the smaller stones forming the inner circles. At South Kensington, or the British Museum, these might well be shown, and they would much help to add to the architectural and archaeological teachings of those valuable and so useful collections. This could not be a very costly matter; but it would help much towards the idea of forming, by degrees, a complete exposition of the first beginnings, and then "progress" of architectural art. There is, most certainly, far more of art teaching in these so rude monolithic blocks than at first sight appears, and it is fortunate that attention has been called to such a monument of the dead past as Stonehenge. We cannot but most fully agree with the suggestion that has been made—that the attention of the Legislature should be called to it, as an historic memorial, and that it should thus be made *public property*. We can but hope that the House will some day give it a spare half-hour. C. B. A.

LUDGATE HILL, PAST AND PRESENT.*

A NARRATIVE of Ludgate-hill has been written by Mr. W. P. Treloar, which will afford a few hours' interesting reading about that famous highway, its legends and historical associations. The author has contented himself with giving the history of one of the principal streets, recalling its past and furnishing the general and archaeological reader with vivid sketches of the time when gorgeous pageants took place on the Hill of Ludgate, when "royal progresses" were not unusual occurrences, and when the gate opened in the city wall. In such a picture of Old Ludgate we must expect to see a very different order of surroundings to those which now meet the gaze. There were no lofty shops on either side, no iron railway-bridge, and the present cathedral with its dome, was not in existence; but the old one, with its long nave and lofty, central spire. Standing on the rise of the Hill, the author carries the imagination back to the time when the palace of Bridget's Well, or Bridewell, stood; when the brawling stream of the Fleet was crossed by Fleet-bridge; the Friary of the Dominicans, once the seat of Parliament, existed; also the old Bail Hill and Newgate Gaol, and the ancient Lud Gate itself. The author gossips pleasantly about Playhouse-yard, the old Bell Savage Inn; the players, Burbage, Tarleton the clown, &c. That Ludgate-hill was a famous locality in our chronicles, there can be no doubt. Of Lud Gate itself, the oldest is supposed to have had its origin in King John's reign. It was adorned with sculptured figures, purporting to represent Lud and his two sons. These figures, shown by a woodcut, represent them in Roman costume. The writer says: "That there was a town on the site which is now occupied by St. Paul's and its surroundings, and that a heathen temple afterwards, perhaps a temple of Diana, may have stood there, is by no means improbable; nor is it impossible that the town may have had a gate, though it is exceedingly unlikely that in the time just before the Roman invasion it was surrounded by a stone wall, since the Britons were never known to have walled towns—a fact certainly remarked by Caesar, and never contradicted, even when London was spoken of not long afterwards."

The derivation of the name "London," long a question among antiquaries and etymologists, is discussed, but no new light is thrown upon it. The old Roman wall is traced, and several interesting archaeological discoveries are sketched, including the large Saxon cemetery on the site of Old St. Paul's, remains of Roman interment; and we find mention made of the urns, lamps, lacrymatories, and coloured glass, and earthenware—specimens of which were only lately dis-

* Ludgate Hill: Past and Present. (Illustrated.) London: Griffith and Farran, Ludgate hill.

covered in the churchyard during recent alterations.

Mention is made of the Fleet river, its course, and its gradual conversion, by the increase of population, into a ditch; of Bridewell, once a palace and fortress, in the line of the old wall, which commenced at the Tower and finished its circuit at near the foot of the present Blackfriars-bridge. Bridewell continued to be a Royal palace till the death of Henry VIII. Graphical accounts are also furnished of Baynard's Castle and its intrigues; of the "Wardrobe" Old St. Paul's, an engraving of which is given; also Ludgate Prison, Lollard's Tower, many reminiscences of which are narrated.

The chapter on "The Origin of Bell Savage Inn" will be read with interest; and the author crow is into a few pages a good deal of reading. Its numerous titles have perplexed the antiquary. In one document it is called "Savage's Inn, otherwise the Bell on the Hoop," and this is the earliest mention of it. It was the property of one Isabella Savage, whose name appears to have been the origin of the title. In more modern times, says Mr. Treloar, it bore the name of "La Belle Sauvage" and this title is thought to have been derived from the custom among the Tudors and Stuarts to make anagrams, and to convert them into rebuses or pictorial tokens. Thus it is easy to imagine Isabella Savage or Bella Savage converted into "La Belle Sauvage" or "La Belle Sauvage." The author says: "The place is sometimes called the Bell Savage, and in later times Old Bell Savage." This may suggest a rather simple derivation, when we consider that the ancient building, like the great pile which covers its area to-day, was close to, and one portion of it may have opened upon the ballium or bailey (which at one time would have been crossed by a bail or bar of wood), the residence of the High Bailiff and the bail or boundary of the district. Now as the Inn was the mansion of the Savage family and near the bailey or ballium, it is at least conceivable that it would come to be known as the Bail or Bailey Savage Inn, and afterwards the "Old Bail or Bailey Savage Inn." The pictorial token may have been suggested by similarity in sound between bail and bell.

Describing the hill, the author alludes to the houses of timber and plaster built in overhanging stories, which were not replaced by brick till Edward IV.'s time. The floors of clay and rushes no doubt led to the epidemics which devastated the city, and sufficient evidence is brought forward to show the social state of the people. Ludgate-hill in Elizabeth's time must have witnessed many festivities; the houses were poor, but picturesque, with long gardens sloping to the Thames. The reader's imagination is kindled by fragrant and historical incidents, such as the expiation of Wyatt, and the cutting off of his retreat at Temple Bar; but we pass on. The transition of many old mansions into inns for public entertainment which took place in Shakespeare's time, was the origin of the large courtyards and galleries such as those at the Bell Savage. Shakespeare's Theatre at Blackfriars is mentioned, and allusions made to Doctors' Commons, Herald College, Stationers' Hall, Surgeons' Hall, Paternoster-row, about all of which many interesting particulars are given. The author recalls the changes which took place, the plague of the time of the first James, and gossip about Ben Jonson and his club, Baroque, Shakespeare, and other notabilities. The Restoration and the subsequent plague are recalled upon, the rejoicings and gloom which followed one another, till the Great Fire changed the aspect of Ludgate. The legends of the hill now take a new phase; old buildings disappear and new ones have taken their place, and the author sketches the appearance of the town. The plan of Sir Christopher Wren for rebuilding the city, a scheme abandoned by the architect, and some of Wren's churches are mentioned. It is said that Wren designed the present slender spire of St. Martin's, Ludgate, to give a greater importance to the dome of St. Paul's, before which it stands as we look up Ludgate-hill.

The narrative then takes us to the Ludgate of Queen Anne and the Georges. The royal processions of William III., the balconies and windows hung with rich draperies and Turkey and Persian carpets, equalled in splendour the pageants of Elizabeth. The rebuilding of St. Paul's is briefly described, and many of the incidents of the period are recorded.

A few interesting wood engravings are interspersed through the pages. The view of old Ludgate shows the old structure, with its mask of stone pilasters and niche above the gateway; another is a good view of Ludgate-hill after its removal. The outer yard of the Bell Savage, and other reminiscences from old prints, are appropriately introduced, and lend an interest to the narrative. Not the least instructive part of Mr. Treloar's book relates to the changes and improvements which have taken place. "Ludgate-hill in the New Light," is an interesting chapter. As a readable account of one of the great highways of London, the author's little book is acceptable, and will furnish the general reader with a carefully-prepared *résumé* of incidents and facts, which are to be found only scattered in large and costly volumes.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE Opening Meeting of the Session 1881-2, was held on Monday evening, and was attended by an unusually large number of members and visitors. Mr. G. E. Street, R.A., the president, who wore the chain and badge of the office, and his Royal gold medal, occupied the chair. Nearly an hour was occupied in the preliminary business, including the balloting for new members. The following gentlemen were declared duly elected. As Fellows:—William Leiper, Glasgow; John Slater, B.A. (Lond.), Bedford-row, W.C.; Daniel Brade, Kendal; William Harvey, Whitehall, S.W.; Capel Nankivell Tripp, Gloucester; Henry Thomas Gordon, Basinghall-street, E.C.; William Bide, Ipswich. As Associates:—Robert Barton Morgan, Birmingham; Lawrence George Sumners, Nottingham; John Tweedale, Leeds; Thomas Ames, Bathampton, near Bath; John Henry Eastwood, Red Lion-square, Bloomsbury, W.C.; Horace Thomas Bonner, Lewisham, S.E.; George Elkington, jun., Cannon-street, E.C.; Arthur Edmund Street, M.A. (Oxon), Cavendish-place, Cavendish-square, W.; Arthur Edward Lloyd Oswell, Shrewsbury; George Thomas Poole, Southampton; James Martin Brooks, Wellington-street, Strand, W.C.; Maurice Charles Haubert, Queen Anne's-gate, S.W.; George Borer, Finsbury-circus, E.C.; John Henry Curry, Tulse-hill, Brixton; Alfred Millwood, Oxford-road, Hammersmith, W.; Percy Paul Green, Greenhill, Hampstead, N.W.; Edward William Mountford, Buckingham-street, Adelphi, W.C.; John Wardle Bulcock, Blackburn; Arthur John Gale, Surrey-street, Strand, W.C.; William Jacob Gibbon, Oxford-terrace, W.; Ernest Augustus Eckett Woodrow, Hornsey-rise, N.; Walter Blackwell, Millman-street, Guilford-street, W.C.; Arthur Charles Bulmer Booth, Bennet's Hill, E.C.; James Tolley, jun., Cannon-street, E.C.; Thomas Batterbury, Great James-street, Bedford-row, W.C.; Richard Mauleverer Roo, Lendenhall-street, E.C.; John Malcolm, Queen Victoria-street, E.C.; Henry William Peek, Gower-street, W.C.; Joseph Porter Power, Dashwood House, New Broad-street, E.C.; Edward Alan Jackson, New Court-chambers, Chancery-lane, W.C.; Henry Petit, Welbeck-street, Cavendish-square, W.; Alfred Augustus Bonella, Montague-street, Russell-square, W.C.; Henry Gregory Turner, New-court-chambers, Chancery-lane, W.C.; Andrew Edwards, Red Lion-square, Bloomsbury, W.C.; Peter Dollar, Great Marlborough-street, W.; and Francis Lennox Canning, Palace-chambers, Westminster, S.W.

The President then delivered his Inaugural Opening Address.

It is a time-honoured custom, he said, that the opening meeting of the session shall each year be devoted to a review of our position, the work we have done during the past year, the losses we have sustained, and finally the openings which appear to offer themselves for the promotion of that which, above all, concerns almost all of us: the advancement of the art to which we have devoted ourselves. We all know how much it pleases some of our critics to assert that the objects of this corporation are selfish first of all, and devoted to the improvement of the art and the science of building only in a very secondary degree. I need hardly waste words upon a refutation of such statements. The real object of the

Institute of British Architects is very different: we exist not only because of, but for, our art. It is not because we are architects that we band ourselves together in selfish opposition to the interests of the world, but rather that the interests of the outside world and of the profession may be harmonised and proved to be identical; and equally that our well loved art may be more studied, more admired, better understood, and more widely practised, not only by ourselves but by the public outside our ranks. The real interests of the public and of ourselves are identical. The obligation to carry on the business side of our work upon the highest rules of honour and integrity as between man and man is placed in the very front of the conditions of membership of this Institute. We admit of no compromise or conditions; and the condition of membership here is undoubtedly that of working thoroughly in the spirit and traditions of gentlemen. In addition to this, the practical work which we have to do is, by meetings, by reading of papers, and by discussions, to keep up and increase as far as we can the general interest in and knowledge of our art, without which neither accomplished architects nor an intelligent public will continue to exist. Naturally our work of this sort divides itself into that which relates to the scientific and that which is concerned with the artistic side of our art. I think there has of late years been rather a tendency to devote more time to the former than to the latter; but the art of building, the art of draining, and the like are exact, and do not admit of perpetual discussion. The development of attention to the study of novelty in construction is not always for the advantage of good building. Half the inventors, whose circulars cover our tables every morning, claim as the chief merit of their inventions that they are cheap, and I would that occasionally they convinced us that they were equally lasting. You will pardon me for frankly speaking my mind on an occasion such as this. I maintain that British architects are honourably distinguished for the way in which, as a rule, they deal with all those questions of new forms of construction, of water supply, of drainage, and of the general conditions on which comfort and convenience in our houses depend. English comfort is a proverbial expression almost all over the world, and our architects are fairly entitled to a large share of the credit of its creation.

I wish it were quite possible to make the same assertion with regard to our artistic successes. It strikes me more strongly, the more I think of it, that we cannot quite escape some responsibility for the bad work which is done by builders without our aid. How is it that, with an ever increasing body of architects, educated and trained more and more carefully, the vernacular architecture of the country becomes worse and worse every day? The vernacular architecture of a country is that which the carpenter, the bricklayer, the mason, the smith, or the plasterer does if left wholly to himself. We all know that the time was when little even of this work was wholly contemptible; take even the last century, and in such work one sees a simplicity and restraint in design, and an absence of vulgar display, which make one feel a charm in work most of which never passed through an architect's office. Go from the house built in the suburb of an English country town in 1750, to one of the houses which rise in countless numbers on all hands now, and your verdict as architects and as artists must always, I fear, be given in favour of the former. Compare the two, and you will find that the taste of the eighteenth-century builder was for simple and good work before ornamental, so that he seldom came to the latter at all: whilst the taste of the nineteenth-century builder is to do everything for display, sacrificing the money which might have made his work at least substantial, to an investment in so-called ornaments to the show fronts only of his house, which are costly to put up, costly to keep in repair, and hideous in their glistly unfitness for their place. They have some comely key-stones, ornamental railings and balconies, a few lumps of terra-cotta, cornices and window dressings of elegant character, and highly suggestive chimney-pots; and for the sake of these the house has walls and floors so thin that every sound can be heard throughout, and so weak that in a heavy gale you rock in your bed. For all this, we are only indirectly responsible, but I do think that we must allow

that too many, if not all of us, think too much of the fronts of our buildings, and so have practically brought up a whole generation of builders and workmen to believe firmly that all buildings ought to have one "show front," whilst we so often sacrifice solidity to the pleasure of creating what we call ornament, that we have led them naturally to assume that ornament is an object by itself, to be clapped on to a building at all hazards, and even at the sacrifice of solidity. This large and serious question deserves discussion and action. For, depend upon it, some screws must be very loose indeed in our system if all our work is so wholly outside the world as not to influence the vernacular architecture of the people for good. My only suggestion at present is that our duty is to show, by example, that simple building may be quite as good as extravagant, and that the essence of all good architecture is that it should be solid and lasting before it tries to be ornamental, and that ornament is a feature which grows out of utility, and cannot be applied to a building like a loose-fitting garment to cover defects or to distract attention from parts which are not supposed to be seen. It is unworthy of architects to build what is in its very nature ephemeral, and I wish heartily that, before all questions of style this vital one of solidity were always present to us when we are making our plans. Depend upon it, the builders who have been trained by architects who never build what is not solidly and well-constructed, are much more likely to build for themselves in the same spirit and way, than they ever are if they have been otherwise taught. And, after all, it is the work done by builders without the intervention of an architect that we see wherever we move in this ever-increasing city, and in others similarly conditioned. It is work which it ill-becomes us to treat as non-existing. It is, on the contrary, one of the very first necessities of the day that we should, in some practical way, deal with it.

There is another question to which the one just mentioned naturally leads, and this is one as to the extent to which we may be able to effect, in the interests of our art, the future architectural arrangement of the streets and buildings throughout our great cities. To state the case in this way is perhaps in fact to answer it, as far as relates to direct interference with or influence over what is done by municipal authorities; though as our Institute boasts properly that it is a British and not only a London Institution, our object ought always to be to keep this fact well before us, and to act even out of London whenever the importance of the case demands it. In 1876 the late Mr. Wyatt, in the course of a discussion on Mr. Eastlake's interesting Paper on the Work and History of this Institute, told us that the author had omitted to mention one proof of its growing influence. This he saw in the request, then just made to us, to exercise control over the designs and elevations of buildings in Northumberland Avenue; a request which became, I believe, a law to the extent of making it necessary that all these designs should be "submitted" to the Council of the Royal Institute of British Architects. Well I know not, gentlemen, what the general feeling on this subject is now. Some I know agreed with the view which I took at the time that the position we were taking was a dangerous one and one that could do no sort of good to our art. The taste of the individual members of a council may be excellent; but there is an unwillingness on the part of a body of men to criticise too severely, or to agree in suggestions as to the alteration of the work of a brother architect. Opinions differ round our own table as to what is best, sometimes even as to what is good, to such an extent as to end in approval being given to works in a general way to which probably every one of the council in his own heart can see little good. Nor is this all. The elevations alone, which are not complete without plans, are submitted; modifications of a very simple kind alone can be and are advised, the advice is neglected, and the building is after all erected with little, if any, attention to the opinion of the council of this Institute. In the end, if Northumberland Avenue ever becomes an avenue of buildings, the Institute will have to ask itself whether the control it has exercised has been sufficiently strong, and the result so good, in comparison to that of the streets in which we have not been able to interfere, as to justify Mr. Wyatt's anticipatory satisfaction. For myself, I have no hesitation in saying that it

would be better, if we are to have no more power than at present, that we should have less.

I do not think it right to close the few words I have thus said on the Northumberland Avenue question without endorsing what fell from my predecessor in this chair on the subject of architects who are members of the Metropolitan Board. He was speaking of the business relations which constantly bring members of our body, as well as the Institute itself, into correspondence with the Metropolitan Board of Works, and he concluded with the expression of an opinion, in which I concur so completely, that I think it only right to repeat it. Mr. Whichcord's words related to the composition of the Board. "Architects," he said, "may be elected members of that Board, just as barristers, solicitors, and doctors may be so elected. It would be ridiculous to say that professional men shall not sit at that Board because they may have had a pecuniary interest in some of its public building transactions. But I shall run no risk of censure when I say that a Fellow or an Associate of this Institute, if he be elected a member of the Metropolitan Board of Works, ought not, from that moment, to have any professional connection whatever with the purchase of land offered for sale or lease by the Board; nor should he be professionally engaged in the superintendence of buildings to be erected on land which is the property of ratepayers whose agent and representative he is." Such a statement is so obviously right and beyond question, that I am sorry it should still be necessary to repeat it.

Upon the broad question of giving general advice through our Council, I feel sure that the Government, or the governing bodies of our great cities, might well, and with advantage to themselves, consult us from time to time on the preliminaries of great building operations; and I have no sort of doubt that we should always be willing to give the best help in our power. Whether the points to be settled are the best routes for new streets, the best sites for great public buildings, or the best openings for architectural improvements, it would be advantageous to every one if the subject were laid before a committee of experts—such as the Council of this Institute is—for its advice and opinion. Take such cases, for instance, as the choice of a site for the New Courts of Justice; or as to the choice among various schemes for the placing of the new Government offices which are even now required; or as to the conditions on which railways are to be brought into London or across our river, and it is obvious that our opinion might well be asked, and almost certainly be acted on, with advantage to the world and without prejudice to any one. In the last case, for instance, can it be doubted that, if we had been consulted, the House of Commons would never have allowed the London, Chatham, and Dover Railway to erect its bridge across Ludgate-hill, and to erect a second and almost equally ill-placed bridge across the Thames, within a few yards only of another built on wholly different lines? Nor would the South Eastern Railway have been permitted to build the two gigantic and odious sheds on the river-side, which have been the ruin of so much of the beauty of the matchless prospect. Such subjects lead me to say how useful a function this Institute might perform if it could keep a more active surveillance on the mode in which the works of deceased artists are dealt with. I am not among the passionate admirers of such a work as the General Post-office; but, at any rate, it was a consistent design, carried out in an honest and uniform spirit, and complete in outline and character. New wants have arisen since it was built, Rowland Hill has come and gone, and more and more accommodation is required. But it is almost beyond credence, that some of that increased space should have been obtained by a series of erections on the roof of the original building, hideous in themselves, and wholly careless of the effect produced, or even of having in themselves any architectural character at all higher than that of a third-rate house or workshop. Yet so it is. And perhaps it was because for years the porticoes and colonnades of another great public building—the British Museum—were entirely filled with glass-encases and partitions, without any entry from the public or from us, at such a defacing of a consistent and costly design, that the Government which represented the country was so heedless of the monstrosity of which it was

guilty, when it made the additions to the Post-Office. Nor is it out of place here to ask when the front of the Colonial Office in Whitehall is to be finished? Its architect evidently prepared for the erection of two towers or pavilions at the angles of the chief front. His proposals were not acted on—and there to the present day stands the building, with its two most important angles evidently unfinished. Every day a large proportion of the members of both Houses of Parliament, and most of the Ministry, pass under the walls of this unfinished front, without I suppose one thought of the injustice done to the memory and reputation of one of the greatest architects of his time. Surely on such a question as this, this Institute, if no one outside will move, ought to take some action.

Then again I hope we are all agreed that there is no work in which we can as a body do better service to our art, or more certainly show our real sense of its value, than by sturdily opposing all schemes for the destruction of existing works of architectural art, or constructions of historical or archaeological interest. We have a committee for the conservation of ancient monuments; it is a strongly constituted committee, and its existence cannot be too widely known. There is always work for it to do. Take, for example, the case of the City churches. When I return from some foreign travel, and cross the railway bridge into Cannon-street, I feel a pride in the architectural beauty of the City of London, which is never lessened by contrast with what I have been seeing elsewhere. And to what, may I ask, is the beauty of this view owing? There is a magnificent river and a sublime bridge, but beyond and above these a cluster of towers and steeples, of so much variety of design, so skilfully treated, so picturesque from every point of view, as to afford unending delight. In the year 1800 there were 107 churches in the City, in the year 1877 only ninety-five remained, and of these there were no less than thirty-one scheduled as "at present" to be pulled down. Only the other day another of Wren's reputed churches, St. Matthew, Friday-street, was said to be condemned, and though the particular case is not a strong one, it seems to me high time that this Institute should strain every nerve in order to save any more such regrettable destruction of the buildings to which London owes so much of its pre-eminent beauty. If architects stand by quietly, it may be assumed that there are no artistic objections to such destruction. We may still permit men to go on in the cheap and easy fashion of making our ancestors' piety and liberality pay for building and endowing churches which we, with all our increased wealth, choose to think we cannot afford to erect; and by the time that all the empty churches (consequent largely on a non-resident clergy) have been removed, and their sites sold for counting-houses, shops, banks, and what not, men will awake to the discovery that the architectural beauty of the city is a thing of the past, and that the loss is irremediable. At the West-end I hope the same words of warning are not required. Your council have been appealed to in reference to a rumour that St. Margaret's, Westminster, was to be taken away. This is a constantly recurring rumour. The penny-aliners probably think that everyone wishes it removed. They forget that it has just been refitted at great cost, that it is a building full of architectural and historical interest, and they are not aware that the builders of our great churches and cathedrals, being artists, had never any objections to the erection of small buildings near to, or in contact with larger ones, to which they gave infinitely more value and scale than they otherwise possessed. I am glad to be able to assure you, however, in this case, on the best authority, that there is no foundation whatever for the rumour. It is remarkable to notice how much is lost on all sides for want of some active hands to save threatened works of art. We look round on the Paris, the London, the Florence, the Cairo, the Venice of our youth, and find that on all sides work has been destroyed, apparently mainly for the sake of change, for the loss of which no new building will ever atone. In London there is the well-known case of the colonnade of Burlington House taken away upon the understanding that it should be rebuilt, but lying in a mouldy heap somewhere on the other side of the river. In some similar limbo, we suppose, are the stones of Temple Bar, for the re-erection of

which in some spot not far from its old place, such for instance as an entrance to Temple Gardens, one would suppose that funds might without difficulty have been found. Farther to the west is an even more interesting work—the water gate at Buckingham-street, Adelphi—treated in an even more ingeniously spiteful way. For here the lovers of the beautiful have created a garden with lawns and shrubs and winding walks, which one would suppose might have been allowed to undulate as well as to wind. At any rate even now the level of the garden might be lowered for some distance on either side and in front of the gateway, and Luigi Jones's work might again be seen in its integrity, instead of being earthed up to nearly half its height, and of having its archway used as a receptacle for rubbish, and the decay of its old stonework hastened as much as possible by the piles of damp earth and plants carefully placed against it by the landscape gardener. And, to conclude, there is the case of the church in Edinburgh, for taking down and re-building which, on a new site stone for stone, the railway company were bound to, and did, provide the funds. Here again the stones remain in a heap, and the Corporation, unless they are much troubled, have kept the money for their own municipal purposes.

I might easily multiply examples of the same kind. They all seem to point in the same direction—to the necessity in such a country as ours for the creation of a Government department of the Fine Arts, whose office should be not only to give order to our magnificent but often confused and inaccessible collections, but to take care that our national buildings and our historical monuments are classified and preserved as far as possible from further damage either at the hands of time and weather, or at the equally destructive hands of those who have no hesitation in wholly destroying the architectural character of a great public building. I believe that the appointment of such a ministry might be followed very soon among other things by an addition to our museums, which has often been urged strongly—but hitherto unsuccessfully—of a museum of casts. Every one admits the advantage to students of art of such a museum. Berlin has shown us the way, and the expense could not be so great as to be a difficulty in the way of so rich a country as this is. Moreover it seems to be a necessary complement to the other collections which have been accumulated within the present century, as affording the very best means of educating the eyes of a people who are undoubtedly holding their own against foreigners in all artistic matters far better than they did before such museums were first of all formed. The collections at South Kensington contain a good many most valuable casts, but they represent only comparatively modern art, and even then are in no degree whatever complete, and they are not, as they should be, exhibited by themselves, or classified in such a way as to be thoroughly useful to students. I hope that no opportunity will be lost of pressing upon Government the sense that this Institute must feel of the importance of such an addition to our national collections. It is a feeling which is sharpened in us by the knowledge of the fact that such a museum would, to a very large extent, illustrate the close connection which ought to exist between the work of the sculptor and the architect. The best work of the greatest sculptors have nearly always been their decorations of architecture; and the evidence of this necessary connection before the eyes of the people is the best way of familiarising them with the fact, and of leading them to feel the want in our own buildings, in which, even when the architect has advertised his desire to see sculpture introduced, the spaces he has left for it are still, as a rule, conspicuous by their emptiness. The Government which, with a large and wise liberality, would deal with such questions as these, would secure for itself perhaps less temporary popularity, but would have the satisfaction of knowing that it more permanently benefited the highest interests of the community than it could by exclusive attention to purely political questions, and as such work ought to be independent of party, what one set of ministers undertook would not be likely to be undone immediately by their opponents and successors in office.

At a recent Conference, the question of competitions led to much discussion, and the resolutions arrived at have been discussed by the

Council, who will ere long lay before you the result of their deliberations. The position which I hope will be taken by you will be to arrange that in the event of a competition being indulged in, due securities should be given for really accomplished assistance, or advice, or judgment on the competing plans, not only in regard to technical questions as to compliance with conditions, but at least as much on true artistic questions, which are even more to be thought of, more vital, and more difficult to settle. But it is, I hope, no part of our business or duty to do so much in the way of facilitating competitions as to lead the world to suppose that we are in any sense whatever admirers or encouragers of a system, the defects of which, under the best arrangements, are so many and so patent that the best men keep themselves wholly or almost entirely out of reach of them, with the result that works which result from competitions are seldom those which we look back on with the greatest satisfaction.

Our Conference in its discussions leaned rather to the merely business-like side of our work, but let us hope that this was corrected in some degree by the visits paid to various buildings and collections in the metropolis. Of the latter, those to Buckingham Palace and to Sir Richard Wallace's were the most important. Probably we all regretted that the palace of our well-loved Sovereign was not more worthy, in structure and in decoration, of so great a monarch.

Our numbers still continue to increase. Last year at this time the total number of fellows and associates was 716. The additions during the year have been 23 fellows, 143 associates, 9 honorary associates, and 9 honorary and corresponding members; and deducting the losses which we have sustained by death or otherwise, our numbers now stand at 370 fellows and 491 associates—a net gain of 19 fellows and 126 associates. It is to be hoped that this large accession of new members does not mean that we are reaching a lower level of qualification so much as that the Institute is becoming more recognised as the centre of our work. A large increase of members involves also an increase of our means, and additions to our library, which is rapidly increasing and is now of great value. Another addition to our means of doing good work is Mr. Godwin's generous foundation for the promotion of the study of modern structures and building improvements and adaptations. This has the special peculiarity of being open to all members, and though it is not educational in quite the same sense as most of our other prizes, it will, there can be no doubt, be of high value in its results to the profession.

Of the losses which we have sustained during the year, a few words will suffice, in addition to what will appear in the *Transactions*, upon some of the names whose absence from our ranks we deplore. The death of William Burges took from us unexpectedly, and in his full vigour, one whose belief in his art, whose devotion to its study, whose enthusiasm for his work have rarely been excelled. A student from first to last, an artist whose hand was always seen in every detail of his work, his example is one to be held up always for our admiration and emulation. He knew that unless an architect's work is good and thorough it has no enduring life. He knew that this lesson required to be taught us more than any other, and he made it the business of his life to teach it; and I honour him the more that he gave to others what he had with infinite pains learnt. It was one of his greatest pleasures always to discuss in public or private old modes of procedure, of manufacture, of design. There was nothing selfish in his acquisition of architectural or archaeological information. He was as ready to communicate as he was to acquire, and many of his published papers are replete with learning and information. The study of Early French Pointed architecture had evidently produced a very strong and lasting effect upon him as an artist. He revelled in the somewhat rude and ponderous version of it which he affected, and it was in the sculpture and the decoration with which he rejoiced to overlay his work that he allowed his quaint and exuberant fancy to have full play. There was so much originality in what Burges did that his work was certain to be criticised. It was warmly admired and as warmly opposed, and he would have been the last man to wish it otherwise. In one thing at least all were agreed, and this was that his death was a real loss to our art. The Royal

Academy has at last recognised his undoubted claims; and, unfortunately, it still remained for this Institute to follow with a testimony in the shape of the gold medal, the bestowal of which, I am sure, could not have been much longer postponed. In Frederic Ouvry we have lost an adviser, who was not only always ready to give us his valuable counsel whenever we asked for it, but we had the satisfaction of seeing combined in him the able solicitor and the accomplished antiquary. Among foreign architects, whose deaths we have to deplore, are some of great mark. Hector Lefuel, Member of the Institute of France, was well known by his works to many of us. The names of Davioud and of Mariette Pasha must not be forgotten. Both of these did great work in different directions, and will long be remembered among us, the former especially by what certainly was a bold flight of genius—the Trocadero building, and the latter by his good work among the monuments of Egypt.

The architectural publications of the year do not appear to be numerous. I cannot say how much I regret this. Nothing tends more to raise our art than some attention among us to these literary illustrations of architectural history and style in which so many architects have in past times distinguished themselves. We have examples in the case of some of our oldest members which may well be commended to the notice of their juniors. Nothing, let me assure them, so certainly gives young men their first footing on the ladder which leads to fame and success. Our old Librarian, Mr. Dollman, has shown us how valuable a work it is possible to produce in his monograph of St. Mary Overie's Church, as to which I have already had great pleasure of expressing my opinion here. The Society of Dilettanti has published another part of the "Antiquities of Ionia," in which, seeing that Mr. Newton, Mr. Watkiss Lloyd, Mr. Fergusson and Mr. Pullan have combined their forces, we need not doubt the result. The magnificent government work, the "Monumentos Arquitectonicos de Espana," is still going on, and we are looking forward to the early publication of Herr Richter's promised edition of Leonardo's "Trattato della Pittura"—a work which will have almost as much attraction for architects as for painters, for among the many hitherto unpublished drawings which will be contained in it some, I understand, are architectural designs. No great public works have I think been completed during the year. At Vienna, at Brussels, and in Paris great works are approaching completion, all of them undertaken in a spirit of lavish expenditure, which is somewhat surprising to us in this country. The Cathedral at Cologne has been completed—the most gigantic work of modern times—in presence of which all unkind criticism ought to be hushed in admiration of the grandeur of the idea. The so-called restoration of St. Mark's, Venice, has, I hope, for a time been arrested—whether permanently or not it is impossible to say. Only too frequently works are done for which the necessity, if it exists, cannot but be regretted. Such a case is that of Coutances Cathedral, where the north-west steeple has been just made to look as it might have done, when first built, by the obliteration of every mark of age. I most sincerely trust that this may not be the forerunner of an entire scraping of the whole of this magnificent church! The question of the restoration of ancient buildings is one which is constantly coming up for consideration, and I am constrained to say that unless the very greatest care and judgment, and the utmost reverence for every relic actuate the restorer, restoration is not only a serious risk, but an unmitigated evil. There is the risk of doing too much and of obliterating every sign of antiquity. Such works in our own country as the redecoration of the Chapter House at Salisbury, or in Germany, such works as the decoration of the Castle at Meissen, and the far more interesting Castle on the Wartburg, near Eisenach; or in France, such as the redecoration of the interior of the Sainte Chapelle, fill me, I confess, with distress. No one wishes more than I do to see our painters at work upon our walls; but I do not wish to see their works obliterating, as they do at the Wartburg, every mark of antiquity inside the building. Our new walls and buildings are numerous enough for all that they can do; and in the repair of old work—it is the repair strictly speaking that is the one thing needful, and beyond which it is undesirable to go. And even

this ought never to be treated as proper work for any but the most skilled hands.

Various matters of considerable practical interest will come before you this session. The proposed repetition of the Electrical Exhibition is one which will be full of interest. Hardly second to this in its interest for architects is the Smoke-prevention Exhibition, which is to take place this month and next at South Kensington. There is small encouragement in London to use the best materials for building, if they are to be defiled as soon as built by the foul atmosphere which we create for ourselves; and our utmost endeavours ought to be given to the cause both of clean lighting and clean warming, if we have any care whatever for the permanent effect of our buildings, both internally and externally. Among other subjects which I hope your council will see their way to bring before you, are suggestions for the consolidation of the Building Act of the whole country in one uniform Act; and the preparation of such a statement on the subject of the law of light and easements as may help to form the basis of an Act of Parliament to do away with the present uncertainty and variety of opinion and practice; and the Council will no doubt feel it necessary to bring before you some amendment on the present mode of electing to the highest office in our body.

Her Majesty's Gold Medal was given last year to Mr. J. L. Pearson, and this year to Mr. George Godwin. Next year, according to the established custom, it will be given to a foreigner. On these occasions it is generally of necessity given to one who has no connection with this Institute, and I do not hesitate to say that if the best man exists in our own profession, but outside our own ranks, we should both better obey the Queen's intention and gain more credit, than if we insist upon regarding membership of this Institute as a preliminary condition for British membership, which is what hitherto we have practically done.

The most serious matter before us for next year is the first Obligatory Examination for admission to the privilege of membership. It would be strange, indeed, if in a land of freedom such as ours there had been but one opinion as to the wisdom of the proposal, but it would be almost equally strange if, in a land of order such as ours fortunately is also, the examinations were not carried out with due zeal and thoroughness by your executive. Some of us may think that old times were not so very bad, and that want of some small preliminary technical culture and education did not prevent many of our British architects from being really great men. But these are not the sort of men who will be affected by our examination, the object of which is rather to raise the general standard of education, and so to keep out of the Institute those who are wholly incompetent, than any vain hope of suddenly creating an unlimited supply of admirable artists. We must not raise our expectations too high, or we shall certainly be disappointed. At the same time I feel very decidedly that it is the duty of the Institute to take care that the examination is a *bona fide* one, involving careful preparation on the part of the candidates, and a real acquaintance with at least the groundwork of an artistic and a professional knowledge. There will be no difficulty in testing satisfactorily the ability of those who come to be examined in many of those branches of our work in which every one who intends to act as an architect ought to be well grounded. The power of drawing accurately and intelligibly plans for buildings which will stand when built, is a *sine qua non*; and there is much work of this sort as to which we shall have no difficulty in framing sufficient tests. The far more real difficulty is in an examination into the capacity of candidates as artists; and here it will not be desirable to make the test very difficult, for I know well under what difficulties students often labour. As a visitor and teacher for some years in the schools of the Royal Academy, where probably owing to the examination at admission the ability of the students is above the average, I have to see with constant regret a singular want of acquaintance with the first principles of architectural design, and with the rudiments of architectural detail, which mark the work of many students. But it would be a fatal mistake to make the artistic part of our obligatory examination so very easy and rudimentary as to allow of even the most ignorant of our candidates scraping through. The examination once instituted must be a real one, in the sense of

meaning that the candidate has at least reached some fixed standard—even if a rather low one—of efficiency all round, and such a standard should, as far as possible, be so settled at first as to remain permanently the same. We are not likely to have a better prepared class five years hence than we have now. All the necessary means of education exist now, and have long existed. The system of pupilage, which enables men to learn exactly how those who have succeeded in making their mark are in the habit of working, is no doubt the strong point of our English system; and this can be supplemented by work in London under the professors at King's College and University College, and both in London and the provinces under the Government teachers. Then there is the Architectural School of the Royal Academy, presided over by an active member of our Institute, and where the students have the advantage—as from the crowded state of the school there can be no doubt they feel it—of the personal teaching and direction of most of the architect members of the Academy in succession. Finally, there are the inducements held out, both here and at the Royal Academy, to the more able and earnest art students, in the shape of prizes more or less attractive, and only to be gained by those who have achieved considerable artistic excellence. No one can fail to be struck with the high average of the work which is done in competition for the medals and prizes which we annually distribute, whilst at the Academy, though the excellence of the competition has been for many years very remarkable, I am sanguine that the alterations which have just been made in our laws, with among other things the provision of a travelling studentship of £200 attached to the Architectural Gold Medal, will produce an even better effect. The further new provision of a travelling studentship for travel in the United Kingdom is valuable as showing that the existence of native art worthy of study is at last recognised by the Royal Academy, treading in the footsteps of our own Pugin Travelling Studentship, of which the results have been so eminently satisfactory. Such successes as the gaining of these artistic prizes in competition, either here or in the Royal Academy, will count as somewhat more than any artistic examination which we can conduct in a few hours here; and in the same way that when a graduate of one of our universities presents himself for examination, what he has already had to do for his degree will not require any sort of repetition at our hands. The Institute having taken this examination in hand we must all do our best to ensure its success, and in one respect many of us can do more perhaps than we do. It is the master who does bad or inferior work who ruins the prospects of those whose education he has undertaken, and the better the master's work the better will be the prospect of those who have been trained to look up to him. I may dare to say, in reference to our English School of Architecture, that it has in some respects made marked progress within the recollection of most of us. No school has advanced more in draughtsmanship, whilst the study of ancient examples at the fountain head has become universal among all those who have any enthusiasm or ambition. The individuality of the artist, which is the special mark of English art, is stamped as strongly on our architecture as it is upon the sister art of painting, and I trust that we here shall always steer clear of any attempt to follow foreign systems in this respect. I heard only a short time ago the lively expressions of regret of a great German authority, that their Governmental system of teaching deprived them of the enviable independence and originality which struck him so much in our English system of architectural training.

Let me now say a few words to those who at present do not see their way to joining the ranks of this Institute. They are of two classes—the old and the young; of the former it would be idle to shut our eyes to the fact that some very eminent names do not appear in the list of our members. Whatever the cause of their absence, I cannot say how much I deplore it, and how heartily I wish it were possible to induce some, if not all, of them to give up their self-imposed isolation. We see it asserted from time to time that this Institute concerns itself with nothing but questions of professional practice, professional etiquette, professional payments—that its whole concern is with the professional as

opposed to the artistic side of our necessarily two-sided life. Well, I have spent a good deal of time at your meetings and at your Council table, and my experience is not quite so dreary as these statements would, if they were justified by facts, make it. But those who think that less than the right amount of interest and time is given to artistic questions should by joining us strengthen the hands of those—among whom they may count me—who more or less agree with them. No one is more loyal than I am in every respect to that Academy of the Fine Arts to which it is my good fortune to belong. Were this Institute in the least degree hostile to it I certainly should not have the honour of occupying this chair. But it is impossible to contend that all the artists in our profession are to rest quiescent outside because some half-dozen seats in that body are reserved for a few fortunate architects. It was a wise and noble act, when the Royal Academy was founded, to make its constitution what it was, and to combine within its ranks representatives of all the arts. But our art requires much more than this, and we cannot too much interest ourselves in the work of this Institute, in order, among all things, that the position of our art as an art may more and more be recognised.

One of the aims of this Institute is to regulate—as far as it tries to do so, and that is not very far—professional practice by discipline, which, being suited for gentlemen, is suited for artists; and those who do not belong to us do, most undoubtedly, whether they like it or allow it or not, reap advantages from our existence by their side. If the Institute were even remotely like a trades-union, then no appeal should come from me to these outside brethren. But knowing what its worth is, I do not choose to lose this opportunity of appealing to them to join us.

The younger class is very differently situated. That active body, the Architectural Association, is, in so many respects, working in a groove which runs parallel to our own, that I feel some means might and ought to be devised for enabling its members to join us. There is so much that is admirable in their self-constituted system of education, in the energy in which they pursue their work, and in the high excellence of very much of it, that I rather grudge their securing all the energy of the young for an institution with which we have nought to do. Surely some plan might be devised by which our juniors might, under their own government, betraiding themselves until they gradually fall into their places among us, instead of as now finding themselves obliged to belong to both institutions where one should suffice. The young men want self-government: but I, who am no longer a young man, do not hesitate to say that this Institute suffers much and seriously by their practical abstinence from our meetings, our society, and our work. And if it were possible—and it does not seem to me to be impossible—I should like to see their connection with us established together with full liberty of self-government as to all those educational arrangements which they at present appear to manage so admirably and to prize so much. Few of us grow much better artists as we grow older. A man's best work is generally done between the ages of twenty and forty, and we should all gain very much if our younger friends would occasionally read papers and join in discussions with us older men. What chance there may be of doing anything in this direction I know not; but nothing would give me more pleasure, during my time of office, than having to assist in any such fusion of the two bodies as may be found practicable.

There is again another class which might be more largely represented here, and this is the class of provincial architects. Some of our most distinguished members practise in the provinces, but the number of these who belong to us is very small. But I cannot but regret that no scheme has yet been successfully launched for creating local associations in connection with this Institute, whose members should be bound by exactly the same by-laws, and who either in towns or districts should have the right of electing annually their own representative to sit on our Council. It may be objected that if all my suggestions were feasible and were acted on, there would be no one left outside our ranks, and we should then inevitably attempt to make ourselves a close corporation. I do not fear this, or I should not make such proposals. The British public, depend upon it, will take good

care that it can retain its liberty to employ whatever architect in its wisdom it prefers; and the casual intrusion upon us of an amateur, or of a sculptor or painter, seems to me to be likely to do much more good than harm to us and to our art.

Let me endeavour to gather up the suggestions already made as to the work which lies before us, to be done somehow or other if this Institute is to do its duty by our art and by the world.

We have gone on far too long enduring the existence of bad building on all sides, shutting our eyes to it and declaring it to be none of ours, and that we can accept none of the responsibility for it. Believe me, we are deluding ourselves. If the architects are now more numerous, more united, and so much more powerful than ever they were before, to what purpose is their power if it cannot persuade those who build so badly to build better? The fault, I fear, is with us. We hear architects of position plume themselves on being "practical" men; we see them indulge in so-called practical discussions, whilst they earnestly deplore the over-great attention which others would fain see bestowed on what they call merely artistic questions. So much is said about practice and practical matters that by degrees they cease to realise that the business they are pursuing ought primarily to be regarded as an art pure and simple, and thus looking first of all at the lower side of their art, they end by ignoring wholly the higher side. Don't mistake me. In our art the best artist is the most practical man. There is the highest art in the best disposition of a ground-plan. There is equal art in the best construction applied to a scientifically devised plan, and in the same way there is the highest art in so disposing the plan that the arrangement shall be convenient for the purpose and yet admit of well-balanced masses in the elevation, and well-arranged outlines and skylines. Beauty of detail is inferior in artistic importance to these qualities, but essential of course to a perfect work. I plead that, if we all in due order took this really practical view of the requirements of our art, all our buildings would begin by being well planned, would next be well and soundly built, with elevations meant to bear inspection wherever seen. There would be no sham fronts or false use of materials or deceptions as to construction; and if our nine hundred architect members were all building in this way, depend upon it the day would not be far distant when good building would be so much the fashion, that the builder unassisted by an architect would not care to do such vile work as now he almost always aims at and succeeds in doing. The conclusion to which I have come after many years' experience is that the well and honestly constructed building never excites contempt. We may regret that it has no style, but if it have the qualities just named it may be said to have the first elements of style in itself and can dispense with anything adventitious. That fashions in art come and go, most of us have already seen evidences; but really good work is never out of fashion, whatever its style. One revolution we have seen accomplished under our very eyes. We have lived in the days of compe, we are now living in the age of brick. We have seen the world outside us converted from the use of a bad and mean material to that of a good and honest one; and I am sanguine enough to believe in the possibility of such a change in other respects as may make all building throughout England more tolerable because more honest and less vulgar than it now is. If I did not think this a matter which ought to be taken to heart by every one of us, I should not venture so frankly to state my strong opinions. I hope that I shall not find myself without general support, and that in due time our own consistent determination never to build anything which is not solidly and well constructed with the best art we can bestow, will not only make men honour us for our work, but anxious above all things consciously or unconsciously to build and work in the same way. Certain it is that, when we have accomplished this, we shall have just reached the point which every good school of architecture throughout the world seems to have reached long before its best period.

Sir FREDERICK LEITCH, P.R.A., said his connection with the Institute as one of their Honorary Associates, and his relation to the Royal Academy, combined to render it doubly

pleasant to be intrusted with the duty of proposing a vote of thanks to the President for his very remarkable address. In its forefront, Mr. Street had touched a chord to which every heart in that room must have responded by his forcible and energetic protest against the depraved vulgarity of the weary acres of buildings which were continually rising to the right and left of us, structures in which the hand of the architect had neither part nor lot. The chief sufferer from the want of taste or beauty in a dwelling was its occupant, but the effect of the continual sight of a succession of such buildings was far reaching in its influence on the public taste. Indeed, the constant inhaling of the miasma of ugliness thus generated, threatened with death the very sense of beauty. He believed that the real remedy for this growing evil had been pointed out by the President. It was to promote a love in the public for solid, simple, plain workmanship, because to minds accustomed to see such work, and imbued with this love, the desire for meretricious tawdriness was totally foreign and repugnant. The remedy for the evil, then, was the regeneration of the public taste by evoking the due appreciation of all honest and artistic work. The President had been inspired by the triumphs of the production of ugliness with the suggestion of the appointment of a Minister of Fine Arts. In theory, there was a great deal to be said in favour of such a scheme. Such an influence exerted by the State, to check all that was bad and to foster all that was good in public taste, would appear at first sight to be most beneficent. But he could not help feeling there was much to be advanced on the opposite side. The public taste was, after all, in the long-run the arbiter as to what was good and what not good. Any effort by the true architect to run counter to this would—while this grotesque indifference to beauty and this callous indifference to ugliness and the hideous continued—be, he feared, a life-long struggle against the serried and stolid ranks of the Philistines. He rejoiced very much to hear their President give prominence to one scheme in which he had himself for some time taken some interest, but in vain—he alluded to the President's earnest plea for the formation of a large collection of casts, such as they might see Berlin, Paris, Munich, and even one of the chief towns in little Switzerland possessed. Very much could be learned from such casts, which could not be acquired by the student so well in any other way, and he was surprised that this country had not done more to establish a museum of casts. The President had mentioned the new schemes which had been propounded with the aim of increasing the usefulness of the Royal Academy school to young architects, but he had omitted to allude to one feature of the scheme by which the Academy was endeavouring to unite more closely the three arts of painting, sculpture, and architecture: he referred to the proposal to eliminate any barriers that might have existed between the three arts by allowing the students of one to attend all three classes. These new rules were made with the earnest hope that they would aid in consolidating and strengthening the three professions which were one kin.

The Right Hon. A. J. B. BEESFORD HOPE, M.P., seconded the vote of thanks to the President for his long, extremely masculine, able, sensible, well-spoken, admirably-composed address—epithets which he applied to it not as a fluffing string of adjectives, but advanced critically by one who has undergone in the remote past some of the heart-searchings which must be felt by one who addressed the members from that presidential chair. In one of his own very inferior productions he also had dealt with the proposition to establish in this country a State Minister of the Fine Arts, but he had looked at it from a different standpoint to that taken by Mr. Street. There was, he feared, great danger that the actual work of such a minister would devolve upon one of those artistic productions known as the permanent official, who would be the suburban builder in *exelsis*. All who had to deal with public offices knew that behind the member of Parliament sitting on the front bench, and nominally having the control, was the vague shadow of his master, the permanent under-secretary, who alone knew the inner workings of the office. Let them beware lest the permanent under-secretary of the minister of fine arts had in reality become the

permanent overseer. Again, the Minister of Arts must necessarily be removed and replaced with the mutations of party politics. In one ministry, a man with artistic tastes would encourage and foster art, but the next ministry, in consequence of a war with the Cannibal Islands, might find it necessary to economise, and would select for this post an officer who would cut down the public arts to the quick. Again, such a minister must not be so powerful that he would override the great independent organisations which were doing so much for the art of the country, such as this Institute, the Royal Academy, and the British Museum. After some eulogistic remarks on the work of the Institute, which he said could never justly be sneered at as a mere trades-union, Mr. Beesford Hope closed by seconding the vote of thanks to Mr. Street for the address with which he had cheered, elevated, and instructed them.

The motion having been carried amidst loud applause, Mr. STREET briefly replied, saying that, while there was much to be said in answer to points raised by both speakers to the motion, he would not detain the meeting at so late an hour. He was perfectly aware that his suggestion of a Minister of Fine Arts required guarding in the most careful way to make it practicable.

RHIND LECTURES IN ARCHÆOLOGY.

THE concluding lecture of this course was delivered last week in the Masonic Hall, Edinburgh, by Mr. Joseph Anderson. The subject was "Hill Forts, Vitrified Forts, and Ground Structures." The lecturer observed in the outset that there was no class of ancient remains within this country of which they had less precise knowledge than the hill forts. The reason of this was not their rarity, because they formed perhaps the most numerous and widely distributed class of ancient structures now existing, but the ordinary methods of obtaining precise knowledge of their form, structure, and contents had not been applied to them, and the ordinary agencies of destruction incident to a high condition of social and agricultural progress had long been busy among them. They differed essentially from all other constructions, because they were adaptations of natural sites for defensive purposes. The natural site was the defensive position, and the fort thus derived its form, and in many cases also its character of construction, from the nature of the eminence or promontory on which it was built. It would, therefore, be contrary to the nature of circumstances to expect that they would exhibit anything of the uniformity of plan or structure which was exhibited in thebrochs. Still, it was clear from the little they did know of them that there was certain groups possessing certain features of construction in common, which differed from other groups possessing certain features of construction in common; and it was evident that if a sufficient body of materials existed on record regarding the different members of those groups, their typical characteristics might be readily traced. In the mean time, it was only possible to indicate some of their general characteristics as exhibited by a few of the better-known examples. They naturally divided themselves into two great classes by their construction—first, those that were of earth; and second, those that were constructed of stone. In most cases the earthworks were so low and slight that they could not have been of much service unless crowned with palisades. They were usually on sites that were more susceptible of cultivation than the hill-tops, which were the common positions of the stone-works, and hence they had suffered more generally from agricultural operations than the forts of stone. They were usually irregularly circular or oval in plan, consisting of a varying number of low embankments drawn round the summit of a natural eminence. The hill forts, which were constructed of stone, sometimes consisted of a single wall drawn round the brow of a hill, and inclosing the more or less level area which formed its summit. One of that description at Garrywhone, in Caithness, was an oval enclosure, about 200 paces long by 65 in breadth. The foundation of the wall was about 15ft. thick, and in some places 3 or 4ft. of its height remained. In the thickness of the wall on the east side the remains of two chambers were visible. There were two entrances to the area of the fort—one at the

north end and the other at the south end of the hill. The entrance at the north end had three of the great corner-stones of the gateway still in position. They were single stones or flat boulders, about 5ft. high, set on end. The dilapidation of this remarkable example of a stone cashel was due to the construction of a mill-dam in the valley below, the stones having been rolled down the hill to form the embankment. He noticed it because it was the only hill fort he had seen which still retained the stone pillars of its gateway, and because the story of its demolition illustrated the fate of many of the most perfect and interesting remains of this country's antiquity. A more complex variety consisted of two, three, or more walls drawn concentrically round the upper part of a conical hill, as in the case of the example known as the White Caterthun, Forfarshire. There was another variety of those hill forts which had attracted more attention, on account of the singularity of the phenomena which they presented. These were the vitrified forts, because in their walls there was always more or less of the scorified or vitrified appearance, which was the result of the action of fire upon masses of loose stones. Having described several of these, and pointed out that there was not sufficient evidence to establish that the vitrification was a method of construction, the lecturer proceeded to observe that there was a class of underground structures of peculiar form which was common in Scotland, and was entirely unconnected either with hill forts or any other variety of defensive structure. They were mostly situated in arable land now under cultivation, and they had usually been discovered by the plough coming in contact with the roof. One had been so discovered at Broonhouse, in Berwickshire. It had been known before, and most of the roofing stones removed; but on this occasion it came under the observation of Mr. Milne Home, who communicated an account of it to the Society of Antiquaries. At Migvie, Aberdeen-shire, an underground structure was discovered in 1862, and was described and figured in the proceedings of the Society by the late Mr. Andrew Jervise. The similarity of these two structures was not less striking than the excessive peculiarity of their distinctive features. These features were—(1) their position underground; (2) the contracted entrance; (3) the form of the chamber—a long, low, narrow and curved gallery, gradually widening inwards; and (4) the construction of the chamber, with convergent side walls supporting a heavily lintelled roof. Many examples possessing such typical features had been discovered from time to time in various parts of Scotland. They were numerous in the upland districts of Aberdeenshire. Closely analogous to these in its main features was the underground structure at Buchaam, in Strathdon, described in a communication to the Society by Dr. Arthur Mitchell. Another one at Eriboll, in Sutherland-shire, described by Dr. Mitchell, was peculiar for the smallness of its size, being nowhere more than 4ft. in height, and, for the greater part of its length, only 2ft. wide. Dr. Mitchell remarked that it was difficult to see what purpose such a structure could have served; but he added that it was worthy of note that in that district similar underground constructions were not rare, and that they were called by a Gaelic name which signified hiding-beds. Whatever might have been the actual purpose or purposes to which they were applied, the fact which was of importance in this investigation, was that these structures, though varying in area, from Berwickshire to the north coast of Sutherland, were all of one special character. Occasionally they occurred in considerable groups, as at Airlie, in Forfarshire, and Kildrumny, Aberdeenshire. The lecturer proceeded to notice a few examples, which, by their associations or their contents, disclosed indications of the period of the type. Indications, he said, had been found in connection with the structure and contents of these singular buildings which carried the period of their construction close up to the time of the Roman occupation of the southern portion of Scotland. Objects of the Roman period had been found at Tealing, Pitcur, Newstead, and Crichton Mains, Mid-Lothian. Of the culture and civilisation of the people who constructed these strange subterranean cells, it might be impossible in the present condition of their knowledge to form an adequate estimate. But they could say this of them with certainty, that whatever might have been the

special motives and circumstances that induced them to give this peculiar expression to their architectural efforts, they exhibited in other respects evidences of a culture which, though it might be inferior in range and quality to that of the Christian time, was nevertheless, so far as it went, of even higher quality than that exhibited in association with the vastly superior architecture of the brochs. And while on all these lines of investigation they had traced the manifestations of these early forms of culture and civilisation up to points at which they touched the culture and civilisation of the Roman Empire, it was to be observed that they did no more than touch it—they were not merged in it. In all their distinctive features they were still Celtic in character, and Celtic exclusively. There was nothing Roman in the art that decorated those forms; there was nothing Roman in the architectural character of the structures in which they were found. The forms, the art, and the architecture were those of Scotland's Iron Age—the Pagan period of the Celtic people.

DWELLINGS FOR THE POOR.

LAST week we gave a few facts and figures touching the difficulty and cost of securing sites for dwellings of the artisan and labouring classes. We now briefly refer to some other statistics which have been collected and tabulated by the Dwellings Committee of the Charity Organisation Society, and which bear upon the momentous problem of housing the poor in populous neighbourhoods. The evidence furnished in the committee's report on this subject clearly establishes the faulty procedure under the Act. It has been well called a "slow and cumbrous method," consuming much time in formalities prescribed by the statute. The Lisson-grove case we referred to last week, points forcibly to the want of a more expeditious method of dealing with property of the worst possible class. The machinery in force for awarding compensation is undoubtedly very defective. After the arbitrator inquires into the claims and makes a provisional award, the claimants object, the objections are heard, and a final award is made by the arbitrator. When the amount exceeds £500 any party may appeal to a jury. The committee justly finds fault with this cause of delay, and thinks the provisional award superfluous, causing useless delay and expense. Mr. Viger's evidence is to the point; why should there be three tribunals when one will do? The appeals are sometimes numerous, and the umpire is obliged to sit several days, counsel represent witnesses, and, after this expense, an appeal to a jury may have to be made.

Then with regard to the basis of compensation, surely the condition and sanitary defects of buildings taken under the Act ought to be taken into account in determining the amount. By the Amending Act of 1879, an arbitrator, if satisfied that certain houses were a nuisance at some date between the official representation and the confirming Act, can deduct the expense of abating the nuisance from the estimated value of houses. No one can complain of the fairness of this mode of assessing compensation; yet it was not recognised in time. The report goes further, and it proposes that when property is allowed to fall into an unhealthy condition and requires reconstruction, the local authority should have power to demolish, and to compensate only for the value of the land and the materials. The evidence showed also the large sums that have to be given for low public-houses. Eight and nine years' profits are demanded for short leases.

With regard to the number of persons provided for in new buildings we have several statements. The population of Westminster was estimated at 235 to the acre, the Metropolitan Association providing dwellings for 1,000 persons to the acre. The Metropolitan Association for Improving Dwellings lodge 1,135 people (five persons to one family) on an acre including open spaces, and the Peabody Trustees provide for 941 persons to the acre. Bearing on this point, it may be noted that some of the land sold to the Peabody Trustees was worth 1s. per foot and more. If used for dwellings, it is only worth 3d. One witness said, in the Whitechapel and Limehouse scheme "we could not pay 3d. per foot and get four per

cent. return." Scanning over the table of prices given for land, we find the lowest price per square foot is 8d., the highest being 13s. 4d., the latter price being for a site in Golden-square. It has also been shown that improved dwellings have increased the rateable value. The rent paid by the labouring class earning less than 41 per week is necessarily small, and the amounts average about 2s. 6d. to 3s. a week. It is very clearly pointed out that the cost paid for sites, clearing old houses, and rebuilding is quite disproportionate to rentals of this amount. Miss Octavia Hill's plan of purchasing houses, purifying and fitting them for habitation, has been found successful, paying 4 or 5 per cent.

Referring to the cost of providing dwellings, it is stated by Mr. Catliff that the cost of erection may be taken at £52 a room. At 7½ per cent. this would be 1s. 6d. per room, per week, and including rates and taxes the rent would be 2s. 2d. per week, an amount more than the lowest class could afford. Looking over the table of the cost of providing dwellings, the Peabody trustees have provided accommodation at from £262 to £315 per family. The Corporation of London have spent £305 per family in Farringdon-street, and the Victoria Dwellings Association £171. All these are in central positions. On Miss Octavia Hill's plan the cost has been about £118 to £130, and the rents vary from 2s. to 10s. We refer the reader to a general return from all the societies which provide dwellings in the metropolis, from which it appears that several of the best known companies do not provide tenements at less than 2s. 6d., the rents being generally 4s. to 9s. Many of these dwellings are consequently inhabited by a class of tenants who are above the class intended to be benefited; it is also of some interest to remark from the evidence of those interested in dwellings of this class that they seldom let in localities where small houses enter into competition. For instance, the small houses between Deptford and New Cross, and in some other suburbs, are let before blocks expressly built for the accommodation of the poor. At Walworth and the new Surrey Gardens estate the same may be noticed. The fact is, the labouring man prefers a small house which he can call his own to a set of rooms on a flat, and when such houses are to be got in the suburbs the temptation is even stronger.

PRACTICAL NOTES ON PLUMBING.— XIX.*

By P. J. DAVIES, H.M.A.S.P., &c.

INSIDE WORK, OR SANITARY PLUMBING.

WE now come to the bath-room, Fig. 120, 55, which has the handles of the cocks fixed over the top part of the foot, as at 42 and 44, 43 being a pull-up quick waste. This waste discharges into the coffee-pot trap 56; also shown at Fig. 95.

It discharges into the 1½ in. B.W. (bath waste) pipe, with not less than 10ft. of vertical pipe, to cause a draught, and from this into the waste-pipe W, and to the gully-trap Fig. 122. All the fittings in the above diagram will be referred to hereafter separately.

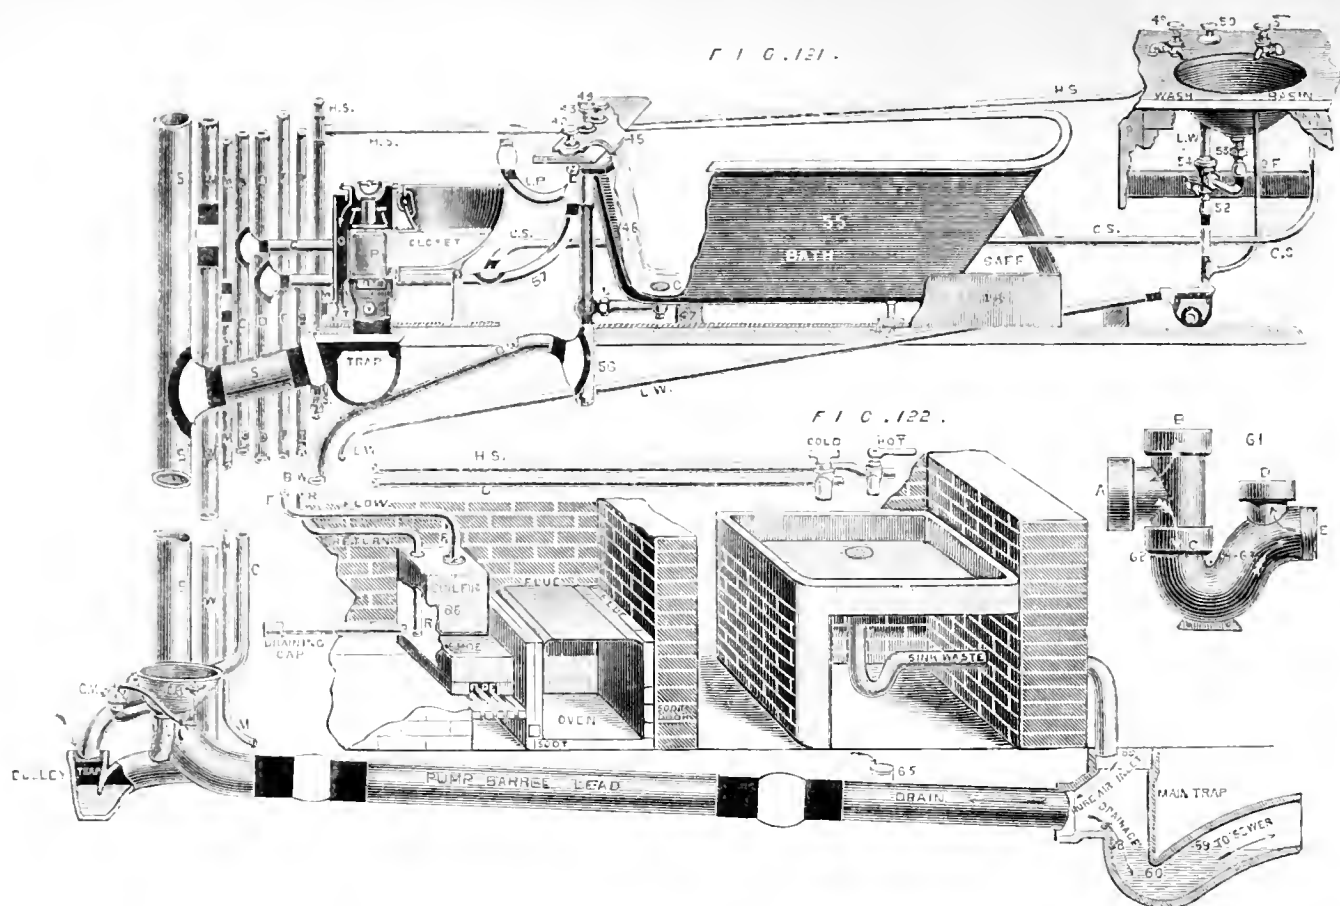

The bath stands upon two pieces of quartering 47, 47, and these pieces of quartering are laid upon the lead safe 48. The hot and cold-water pipe connections are made with 1 in. stout lead pipe 57 and 58, and with welded joints on the linings.

At the head of the bath is fixed a washing-basin, having hot and cold water-pipes C S and H S, with taps 49 and 51 fixed over the top.

50 and 51 is a quick waste, screwed to a board below the basin, and the board fixed to the wall, &c. This quick waste should have at least a 1½ in. clear water way, and run into some kind of trap that will not momentum out, should the handle of the waste be suddenly raised and then let fall, to let out the water to a proper washing level or height.

Here great caution is necessary, for the reason that should the trap momentum out and the water-seal be broken, the gas can freely pass up and through the overflow-pipe, O F, thence through the overflow-holes in the basin. Here suppose a person to be washing his or her face, and the consequent results.

* All rights reserved.

If you trace the run of the H.S. pipe you will notice that it is taken off the bath supply, from off the top of the hot-water tank at 23. Should you require these pipes to be always hot and the same temperature as the water in the circulating (hot-water) tank, you must take the H.S. pipe back again to another part of the tank; but it must be remembered that a difference in the levels must be made in order to get a flow and return; at the same time you must be very careful not to have any of the pipes trapped.

At the foot of the bath is fixed one of Jennings' trapless closets, but over a \odot -trap. This closet is supplied from the closet-cistern (see Fig. 120). The whole of the pipes are so arranged that not one of the pipes hides another, but may be seen or got at for repairs or otherwise at any moment.

The overflow from the bath should discharge over a head outside, as also the closet safe overflow; or if it must, as will sometimes happen, be taken down the inside of the house, let them be taken to a sink or other place where a constant supply of water can be depended upon, should there be any kind of trap employed. If the washing-basin is left unused for a season or a length of time; for instance, during the absence of the family, &c., it would be best for perfect safety to use a ball-trap like Fig. 103, but not like Fig. 102, because, as will be easily seen, one will cease to act when there is not water, while the other acts best without water.

There should at all times be a closet on each floor, and as near the staircase as possible, so that it is within an easy distance of all the rooms, especially the bedrooms. On the dining-room floor there should be a closet, urinal, and washing-basin, and the same near a billiard-room; and, if possible, in all cases keep the urinal distinct from the closet. Most of the water companies in and about London enforce the use of "water-waste preventers" to both closets and urinals, and where this regulation is enforced they invariably insist upon the use of ball-valves instead of ball-cocks.

SERVANTS' CLOSETS.

Though my articles are supposed, and *de facto* are intended to instruct plumbers as to the best method of fixing any kind of work that may fall in their way, I must beg to be excused if occasionally I depart from the absolutely practical path, and endeavour to show, from

moral reasons, why this, that, or the other is necessary and requisite. The question of servants' closets is more important than *prima facie* it may appear—viz., There are many servants who, whether male or female, are particularly delicate in visiting a closet if seen by the opposite sex. This is by many persons of a more obtuse temperament, considered "false delicacy," and, possibly in this respect they may be right to some extent, as of course, the requirements of nature are common to us all; nevertheless, that this delicacy does exist is beyond any argument, and as the want of closet convenience is mainly the cause of the discrepancies in the action of the liver and consequent indigestion, biliousness, congestion, &c., I have thought it politic to preface my instructions on this most important point with the reasons why they should be strictly attended to.

In large houses, where servants of both sexes are employed, it is usual to fix the closets for males and females in the basement, and where practicable, the better method is to place the closets for one set in the front, and the other set at the rear of the house. The advantage in this arrangement does not consist only in the sanitary advantage already alluded to; but it also tends to prevention of unseemly familiarity amongst servants that would otherwise exist. I am, of course, conscious that it will sometimes happen that on account of the construction of a house, it is not possible to follow my instructions by placing male closets at one side of the house, and the female on the other side, but at any rate they should be so arranged that they are not both within the same range of sight.

The above diagram illustrates the plumbing work in the basement of a house, showing the soil-pipe S, brought down with a bend at the bottom, and in this case continued under the house with 6in. pump-barrel, instead of drain-pipes, and carried on to the interceptor or main-trap. This trap effectually cuts off all sewer-gas from the house, which will be evident to anyone if they will notice the water within the well or cess-pool part of the trap as shown at 58 and 59. It will readily be seen that if any sewer-gas does pass from the sewer it must come through the water, as it cannot get through the diaphragm (60). Not a little advantage attached to this trap is that it prevents, to a great extent,

rats making way up the drains into the house (122).

When selecting these traps it will be found best to choose like Figs. 93 and 94, having a drop from the inlet (61) to the water-line (58)—that is, when the drain and pipes run in a right line, as here shown. Mr. Buchan makes a very good trap, as also Mr. Stiff (Weaver's), and Messrs. Doulton (the Croydon) for straight run of drains; but supposing the drains do not run in a right line, or that you cannot get any of the above makers' traps, you can easily overcome the difficulty by the use of an ordinary trap and a square junction, as shown at 61. This has exactly the same effect, and in many cases answers better. Mr. Jennings being conscious of this, is making the trap and a short square junction (J 61, Fig. 122), which may be turned to suit any line of drainage. The dotted lines 62 and 63 show the water-line D, the sewer ventilating socket B, the socket to receive the round grid. A is the inlet to the trap.

VENTILATION.

Now that we are at work with the main-trap it will be as well to prepare for the ventilation of the drains, soil-pipes, &c. This is a point that should never be overlooked, for however good the inside work may be, if the pipes are filled with bottled-up gases of a foul and poisonous nature the whole system is bad and unsafe, to say nothing of the rapid destruction of the leaden-pipes, &c., which otherwise will last ages. (See my letter on "Sanitary Plumbing," July 8, 1881, page 57 of this journal.)

I must now refer you to the pump-barrel drain and main trap (Fig. 122). The simplest, and, in my opinion, the best method of ventilating is the old plan, that can be seen in hundreds of our old buildings. The main drain has an interceptor trap—that shown in Fig. 122 answering the purpose. Next we find the tops of the soil-pipes are made to answer a double purpose, for taking away the rain-water and for ventilation. At the bottom, near about the stump (65), and often at the trap, is fixed a short length of rain-water pipe, and taken into the drain, though not unfrequently is that to be found an open grating, fixed directly over the top of the drain.

Now let us examine the much-talked of new system of ventilation, known as "foot ventilation," &c. On again looking at the main trap

you will notice "pure-air inlet." The arrows show that the air is passing down through the socket, and away along the drain, up the soil-pipe, and out at the top, which should be the highest of a building, as at 27, Fig. 120. This is a true and most simple method of ventilation, totally unfettered by patent law, and with nothing to prevent its being used in the humblest dwellings.

The only thing necessary is to fix the lead pipes with a continual rise, without a lot of bends, more especially sharp ones, as they are great enemies to ventilation. Continue the 4in. soil-pipe the same size to the highest part of the building, taking especial care that no branches enter this pipe unless they are properly trapped.

If you examine the waste-pipe (W) you will observe that it discharges over the mouth of a gully-trap, which enters the main drain. Here again is foot-ventilation, the inlet of fresh air being indicated by the arrow passing onward through this pipe, and discharging itself at 25, Fig. 120.

SERVANTS' W.C.'S.

The servants' w.c. also enters the main drain, but at an easy angle, so that none of the soil from this w.c. can wash back or up the main drain (this applies to all branches). Never let a branch enter the top of a drain-pipe, but near the bottom—in fact the best plan is to let this be down in a bed line.

A, Fig. 123, illustrates the manner in which the sewage runs back up the drain when a junction is put in square with the main. The junc-

tion should be as easy as possible, as shown by the dotted lines.

SCULLERY SINKS.

Scullery sinks in large houses should be provided with proper fat-traps, that is, a large tank to hold sufficient cold water to chill and set the fat, and thus prevent it running off into the drain, because if the fat is allowed to enter the drain, it will clog up the pipes. I shall describe a fat trap in detail further on. In Fig. 122, the sink is made to discharge directly into the main trap, which is a very good plan, provided that the fat is not thrown down in a liquid state.

TRAMWAY CONSTRUCTION.

IN nearly every line of tramway in the metropolis it will be found that a more substantial and permanent system has superseded the earlier construction, and this renewal has been partly due to the cost of maintenance of defective tramways and the consideration that sooner or later horses would have to give place to steam or other modes of traction requiring greater substance in the rails. Mr. D. Kinnear Clark, in his recent volume on "Tramways," noticed briefly by us last week, sketches the progress that has been made in this branch of construction. There were two reasons why the change in laying tramways was made: the old rails were deficient in stiffness, they required a more continuous support to prevent deflection; the timber bearings of the same width as the rails were found to be constantly yielding to the weight of the cars, and it was found impossible to preserve the bond between the rails and the road-paving. It is interesting to glance at the numerous patents which have been brought out to obviate both these defects, and which have been illustrated and described by Mr. Clark. We may first mention Kincaid's system as improved. It provides a wide concrete footing and chairs or sleepers with a long base. The concrete extends under the whole width of way, and upon these are placed long-footed chairs which carry the rails. In the Salford tramways Mr.

Jacob, the thorough surveyor, has introduced a new method of fastening the rail to the sleepers, in which a pair of soft iron cotters were substituted for the wood blocks and the spikes. A continuous bed of concrete is also laid under each rail along the whole line 6in. deep, in which the flanges or bases of the chairs are bedded; a good support is thus provided for the paving next the rails, the sets being supported on a layer of cinders on the concrete. The rails are of iron faced with steel, and the surveyor estimates a life of 19 or 20 years for the rails, allowing $\frac{1}{16}$ in. of wear upon them. The rails are of the box pattern, $3\frac{1}{2}$ in. wide and $2\frac{1}{2}$ in. deep, and weigh 52lb. per yard. The chairs are placed at intervals of 3ft. centres and the details are furnished in Mr. Clark's treatise, to which we refer for further information. At Stockton-on-Tees the Kincaid system is being laid by Messrs. Grover and Newton, with slight modifications. The Southampton street-tramways (Wilson's system) also obviate the disadvantages of the old method of laying. Mr. E. Wilson, the engineer, has adopted the central-web rail with cast-iron chairs, laid on concrete. These resemble in cross-section Barker's sleepers. The rails are of Bessemer steel and weigh 55lb. to the yard. The head of rail is $1\frac{1}{2}$ in. wide, with $1\frac{1}{2}$ in. groove at surface, the guard flange is $\frac{1}{2}$ in. wide at the surface, making a width of $3\frac{1}{2}$ in. The flange is tapered a trifle at the lower edge. The joint chairs have a length of seating of 11in. and 5in. in the others; they are placed at 3ft. intervals and are fastened to the rails by 2 steel middle cotters, and by 4 cotters at the joints. The soles of the chairs are let flush into the concrete, and are bedded in a layer of cement. The concrete is composed of 5 parts of clean sharp gravel, or of broken stones (1in. gauge) 2 parts of clean sharp sand and 1 part of Portland cement. The space between the rails is closely filled with fine Portland cement concrete 4 to 1. The advantage of this system is that the chairs are bedded so that their soles are below the sets.

The Aldred-Spielmann system is being employed in the renewal of the London tramways. The rail (reversible) is composite, of steel, and consists of two halves of the same section rebated with inclined surfaces to fit together, each with a groove rolled in it. The two halves of each rail are laid in cast-iron chairs breaking joint and are fixed by a wooden key. The following are the details given: "The bearing rail takes a square bearing on the raised seat at the bottom of the opening of the chair, and by its inclined surface of contact it holds the guard rail in place. Each half-rail is 2ft. in length, weighs 32lb. per yard. The head of the rail is $1\frac{1}{2}$ in. wide, the groove is 1in. wide and 1in. deep, the whole width $3\frac{1}{2}$ in." The chairs are cast hollow, and give a bearing of 4in. for the rails; they are placed 3ft. apart between centres, and are screwed down on transverse timber sleepers $4\frac{1}{2}$ in. deep, 9in. wide, and 6ft. 6in. long. The systems known as Truswell's and Vignole's have also a large use: the latter has been employed for the North London Suburban tramways, Tottenham; and the North Staffordshire lines, Stoke-upon-Trent. The rails of steel have a central web, and the chairs are placed 2ft. 6in. apart between centres. At Liverpool Mr. Deacon's system has been adopted with modifications by Mr. Clement Duncombe, the city engineer. The use of continuous sleepers of cast-iron was considered assential to a good tramway. The T rail or the centre, groove rail, has been used, and the tramways are laid on concrete. Engravings of the Duncombe modification will be found in Mr. Clark's book, from which it is evident that there are several advantages secured, though the sleepers present vertical faces, and do not give support to the sets as in the forms we have referred to above. One advantage of the system is that the rail can be removed or tightened without disturbing the paving—a feature of some value if only on the score of economy.

FISH-MARKETS FOR THE METROPOLIS.

THE Metropolitan Board of Works last Friday again discussed the question of the Fish Supply to the Metropolis. A motion to apply to Parliament for power to acquire the site now occupied by the works of the Gas Light and Coke Company, near King's-cross, having been rejected by twenty-four to eleven, Mr.

Richardson proposed a resolution which was simply directed to the abolition of the monopoly possessed by the City Corporation. This was also rejected by nineteen to eleven, and the Board adjourned without coming to any decision in the matter.

The City Court of Common Council has received and has accepted the report of the Fish Supply Committee, recommending a definite scheme, and only waits now for the needful Parliamentary sanction before proceeding to carry it out. The scheme is not what the previous week's meeting of the Common Council pointed to. The idea of one fish-market at Billingsgate, or at any other site, has been given up. The view now taken by the City authorities is that there are to be two markets—one for water-borne fish, the other for railway-borne fish. For water-borne fish Billingsgate is still to serve, and it is to be enlarged and improved, if possible, so as to get rid of the present obstructions it offers to free traffic. The more important part of the resolutions passed on Thursday week relates to the new inland market by which Billingsgate is to be supplemented. This is to be established in the central position occupied by the new fruit and vegetable market which the Corporation have been erecting near Smithfield. The difficulty is that the ground and the buildings have other uses assigned to them, and that the transfer of them from fruit and vegetables to fish can be made only if Parliament will consent so far to vary the original plan.

CHIPS.

The districts of Sirhowry and Duketown have just been supplied with water from the Ebbw Vale Water Company's mains. The contract, which has involved the laying of 7,500 yards of new water mains, and of 18,000ft. of lead piping, has been carried out by Mr. J. Gould, of Newport, Mon., and was completed during the present week. The same contractor is now engaged in extending the water mains of the Merthyr local board of health to the village of Vorehriw.

The top memorial-stones of a new Wesleyan chapel were laid on Thursday week, in Queen's-road, South Lambeth.

The Crane coffee-tavern, at Cranbrook, was opened on Thursday week. Mr. Cramp was the builder.

Several of the directors, engineers and other officials of the South-Western of France Railway, and members of Dieppe municipality, visited New-haven last week, to inspect the harbour extension works now in course of execution. Of these works Mr. Banister is the engineer-in-chief, and Mr. Carey the resident engineer.

Memorial-stones of a Baptist tabernacle were laid at St. Alban's on Wednesday week. The building will be of mixed styles—Norman and Gothic—and will measure 79ft. by 40ft. It will be seated for 500 persons on ground-floor, provision being made for the future addition of galleries. Mr. F. Parkins, of St. Alban's, is the architect, and Messrs J. and W. Savage, of the same city, are the contractors. The cost of building and fittings will be about £2,500.

A stained-glass window has been placed in St. Paul's Church, Charlestown, Cornwall. The subject is a figure of Hope; and the work was carried out by Messrs. Heaton, Butler, and Bayne, of London.

An organ, built by Messrs. Henry Jones and Son, of South Kensington, under the superintendence of Mr. J. Norton, of Old Broad-street, architect, is to be opened in Christ Church, North Finchley, on Thursday week.

The committee who have in hand the raising of a memorial to the poet Tannahill, have this week decided to invite sculptors to finish in competition sketch models for a statue and pedestal, the materials in the completed work to be bronze and granite respectively. The memorial will be erected in the Abbey grounds, Paisley.

West Newton Church, near Sandringham, was reopened on Sunday, after having been restored at the expense of the Prince of Wales.

Canonbury Tower is said to be in danger of demolition, in consequence of a rebuilding scheme about to be carried out by the lord of the manor, the Marquis of Northampton. A movement has been organised for utilising the building as a local museum.

At Derby and at Peterborough, two well-known builders and contractors, Mr. Abraham Woodiwise and Mr. John Thompson, have been re-elected to the office of mayor.

INNER TEMPLE LIBRARY.—THE SHAKESPEARE DINING-ROOM SET.—SOUTH WEST VIEW OF WANDALE, CUMBERLAND.—SELECTED DESIGN FOR THE NEW FREE LIBRARY AND MUSEUM, OLDHAM.

OUR LITHOGRAPHIC ILLUSTRATIONS.

THE INNER TEMPLE LIBRARY.

We give illustrations to-day of the additions that have been made to the Inner Temple Library in King's Bench Walk, from the designs by Mr. Robert W. Edis, F.S.A. The design was exhibited at the last Exhibition of the Royal Academy, and our double-page perspective shows the principal front facing King's Bench Walk. The general arrangement of the new building, which forms an important addition to the previous library, a structure in modernised Gothic of a rather feeble type, may be seen by the plans of ground-floor and library-floor we give. The old library and the corner tower are united by a lobby, so that the three libraries can be brought into communication, though it will be noticed the new front is not exactly in the same line as the old building. This difficulty the architect has met in a satisfactory manner by an octagon stair-turret at this point, which forms a pleasing break in elevation, and answers the purpose of the librarian and others. On the ground-floor the porch seen in our elevation opens into a lobby entrance, which will be paved with mosaic tiles, to the right hand of which is a lecture-room for 60 students, with platform at one end. This room has a panelled plaster ceiling, and is to have a dado of oak panelling. The floor is slightly dropped at one end. From Tanfield-court there is a separate approach to set of new chambers by a second octagon stair turret, which forms a projection on this front, giving access to the top floor above the library, which provide for an additional two sets of chambers, with conveniences. Ascending a concrete turret stair, or the main stairs in the corner tower, the visitor enters the new library, which forms two spacious apartments, each about 37ft. 9in. by 22ft. 6in., baying bay windows towards the main front, and lighted also from Tanfield-court. The chief architectural features are the panelled ribbed ceiling and the bookcases. The former is of plaster, relieved by oak ribs, dividing it into large and subordinate panels. A richly-moulded oaken cornice, uniting with the ribs, surrounds the rooms, and this is enriched by some fine carving and a bottom battlemented member, while the main ribs have carved roses at the intersections. The bookcases, which are executed in oak, are in keeping with the style, and a gallery surrounds the rooms, approached by stairs, which are ingeniously contrived between the bookcase and centre wall. The lofty oriel windows have grained ceilings, and the lights are intended ultimately to be filled with armorial bearings in coloured glass. The spandrels have been richly carved, and the plain

sides are relieved by panelled tracery. The stonework of these bays is internally of Beer stone. The archway between the libraries is also of stone, panelled, and double iron doors, working in grooves or cavities, are provided to insure safety from fire. We may also notice here that with the same object the main floors are constructed on the Dennett system; the iron girders being also entirely embedded in the concrete. In the recesses of the windows gill coils are placed, with openings for fresh air in the outer walls. To assist in the ventilation, openings are introduced near the ceilings of lecture-room and libraries leading into ventilating shafts, which are carried up the building and terminate under the turret, which we illustrate, where a gas-cone is placed to create an upward draught. The stoves and mantels have been executed from the architect's own designs, and the carving, both of the stone and woodwork, has been ably done by Mr. J. Frampton, carver, of Barry-road, Dulwich. The exterior is faced with Farnham red bricks of a particular proportion, five courses going to the foot, and the dressings are of Portland stone. It will be seen the style of architecture is that associated with buildings of this class, and the architect has grouped the features in harmony with the semi-Classic surroundings of this locality. The building has been well carried out by Messrs. Holland and Hannen, the contractors, under the supervision of the architect; Mr. Wheeler is the foreman, and Mr. Colin E. Wilson has acted as architect's clerk of works. We hope shortly to supplement the present illustrations by large scale details of the bay windows to the library.

"THE SHAKESPEARE DINING-ROOM SET."

The interior view which we publish to-day illustrates a dining-room, arranged by Mr. Maurice B. Adams, and drawn to show the "Shakespeare Dining-room Suite," which has recently been made by Mr. Wm. Watt, of Grafton-street, from carefully measured details, prepared by Mr. E. W. Godwin, F.S.A. These particulars were chiefly taken from the original furniture, which is said to be either in the possession of Shakespeare's family at the present time, or known to have belonged to him. The whole of the work is in oak, finished with a beeswax polish, and the set consists of eight small chairs, one stool, two armchairs, a side-board and a table. The top of this latter piece of furniture is made in planks, held together by a grooved ledge at either end. We believe that the set may be seen at Mr. Watt's show-rooms.

WANDALE, CUMBERLAND.

WANDALE, the residence of Mr. C. Ling, is situate about five miles from Carlisle, overlooking some of the prettiest country of the Eden Valley. The house is built of warm cream-coloured facing stone from Lazonby with Prudham dressings; the walls are hollow, and are lined on the inside with brick. The joiners' work to the entertaining rooms, hall, and staircase on the ground-floor is executed in Dantzic oak; and the rooms on the chamber-floor are pitch-pine throughout. In the dining and drawing-rooms the walnut and oak mantels and over-mantels are noticeable features. They were made by the contractors for the carpenter and joiners' work, from the designs of the architects, in a first-class manner. The roofs are covered with tiles. The upper portions of windows are filled with painted glass by Messrs. Gibbs and Howard. The pavement, of German tiles, was laid by Mr. L. Oppenheimer, of Manchester; and the granite concrete floors by Mr. Brash, of Lancaster. Messrs. Beatty Bros. were contractors for masonry, etc. Messrs. W. and H. Davidson for the carpenter and joiners' work, Mr. Ormerod executed the plastering, Messrs. Hill the painting and glazing, and Mrs. Johnson, the plumbers' work. A lodge and stabling have also been erected. Mr. Allan was clerk of the works. Messrs. Hetherington and Oliver, of Carlisle, were the architects, under whose superintendence the works have been carried out.

OLDHAM FREE LIBRARY AND MUSEUM.

A DESCRIPTION of this design will be found on p. 573 ante. The author is Mr. Thomas Mitchell, F.R.I.B.A., of Oldham and Manchester, who won the first premium of £100 in the recent competition.

ARCHÆOLOGICAL.

OWAIN GLYNDWR'S PARLIAMENT HOUSE.—After enduring the storms of several centuries, the venerable building at Dolgelly known as Owain Glyndwr's Parliament House, one of the few relics of bygone ages and a monument of the time when the Welsh nation made a final stand for liberty and self-government, is this week to be razed to the ground. Tradition asserts that the building was erected about 1385 as a gentleman's house; in 1405 Owain Glyndwr assembled the last Welsh Parliament, and from this place was dated the celebrated treaty with Charles VII. of France, which, as given in Rymer's "Fodera," runs, "Datapud Dolguelli decem die Mensis Maii, MCCCC, quarto, et principatus nostri quarto." Subsequently it was the residence of Baron Owen, who was murdered by the Welsh banditti of Dinas Mawddwy. It remained in the hands of his descendants until a few years back, and as there were threats of its demolition for the conversion of the site into shops, a movement for its acquisition as a public museum was set on foot by Mr. Holland, M.P., and Mr. Beale, the high sheriff of Merionethshire. Mr. Plipson, architect, Birmingham, prepared plans for the remodelling of the building, but owing to the want of funds the scheme fell through. The curious carved work is to be reproduced in the new building, which will be an ironmonger's shop.

A ROMAN VILLA AT WINGHAM.—The work of exploring the foundations of a Roman villa discovered by Mr. George Dowker, of Stourmouth, in a field called "Vineyards," at Wingham, is being actively prosecuted. The masonry first touched upon proved to be a bath, the walls being covered with black and white tesserae; the floor was also paved in a similar manner, but had been destroyed. Leading up from the bath towards the north are three steps, which lead into a room (No. 1), 10ft square, paved with black and white tesserae arranged in a diamond pattern, and inclosed in a border of alternate black and white stripes. Adjoining and northward of this room is another (No. 2), 12ft. square, paved with black and white tesserae, admirably disposed in a labyrinth fret design, bordered as in the previous example. As far as at present ascertained, the foundations do not extend further in this direction, but on the digging being extended to the west of room No. 1 a portion of the hypocaust was uncovered at a depth of 6ft. The passages through which the hot air passed into the various parts of the building by means of flues have been cleared of the *debris* with which they had become filled by the falling in of the floor above them. The excavations are now being carried on to the south of the bath, where foundations have been touched with the probe some 20 or 30 yards distant, and apparently running in several directions.

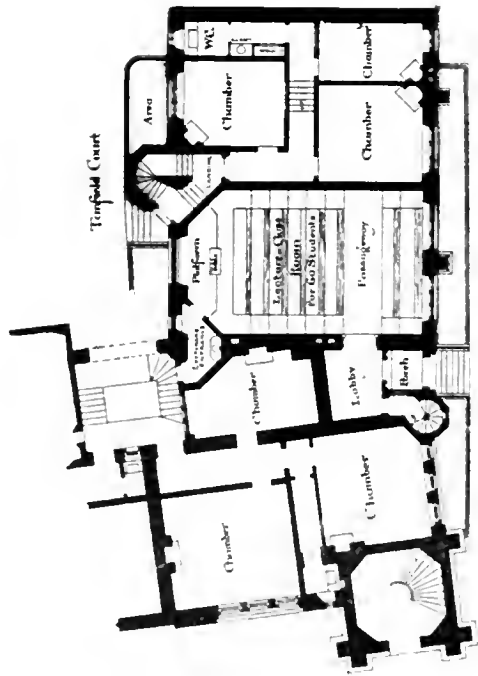

COMPETITIONS.

FULHAM WORKHOUSE INFIRMARY.—The Fulham board of guardians met at their board-room, in Fulham-road, Hammersmith, yesterday (Thursday), to open a report on the thirty designs submitted in this competition by the official assessor, Mr. E. Currey, F.R.I.B.A. The report recommended the premiating three of the designs, viz., "Experience" (in circle), "Simplicity," and "M.D." The consideration of the report was after some discussion adjourned to a special meeting, to be held on Tuesday week, the 22nd inst.

The parish-church of Wilmington, Kent, has just been enlarged by the addition of a new south aisle and heating-chamber, at a cost of about £1,600. The work has been carried out by Messrs. Naylor and Son, of Rochester, from the plans and under the supervision of Mr. W. G. Bartlett, architect, of New Broad-street, E.C.

The Worcestershire Field Club had their autumnal excursion on Monday week, when they visited the churches of Shrawley and Astley, the former a building containing a south door, chancel arch, and other excellent specimens of Late Norman sculpture, the latter also containing some Norman work on south side, but chiefly interesting for the 16th-century altar tombs of the Blount family in the chancel, and the modern tombs in the churchyard of the Rev. W. H. Havergal, and Frances Ridley Havergal, his daughter.

BUILDERS' BENEVOLENT INSTITUTION.

ANNUAL DINNER.

THE thirty-fourth anniversary festival of this Institution took place on the 3rd inst. at the Freemasons' Tavern, Mr. George Burt, J.P. (of the firm of John Mowlem and Co., and ex-Sheriff of London and Middlesex), President, in the chair, supported by about 280 friends of the charity.

The Chairman, in proposing the toast of the evening, "Success to the Builders' Benevolent Institution," said the number of pensioners who had been assisted by it, exclusive of those now on the list, was 129, and there were at present 23 men and 30 women in receipt of annuities at the hands of the Institution. The average age of the men in receipt of the benefits of the Institution was 70, and that of the women 72, and the amounts of the pensions granted were £39 per annum for the men and £27 per annum for the women. The object of the Institution was to grant pensions to master builders, their widows, and others connected with the building trades. So far as in him lay, he would do his utmost to achieve that object, and he was sure that he might count on the hearty support of all the friends of the Institution.

The secretary then read the lists of subscriptions, the total of the chairman's list alone amounting to £1,074 7s. This included £105 given by himself, £105 given by Mr. Godwin, and £827 given in ten-guinea donations. The grand total of subscriptions and donations announced was £1,436 7s. 6d., a sum not equalled on the occasion of any previous anniversary of the Institution.

Mr. F. J. Dove, in proposing "The Chairman," said that among the many services which Mr. Plucknett, their valued treasurer, had rendered to the Institution, not the least was his successful persuasion of Mr. Burt to become the President of the Institution. His presidency would be memorable in the annals of the Institution.

The Chairman thanked Mr. Dove for the flattering terms in which he had mentioned his name.

Mr. Barfield proposed "The Vice-Presidents and Trustees," coupled with the name of Mr. T. F. Rider, who, in responding, said he had to speak in the name of 150 gentlemen, many of whom had done good service to the Institution, while many others were still doing it, or hoped to do it, good service.

The Chairman, in proposing the health of the Treasurer of the Institution, Mr. George Plucknett, J.P., said that gentleman had been associated with the charity from its very foundation, and everybody knew the great services which he had rendered it.

Mr. Plucknett, in responding, expressed his gratitude for the handsome way in which the Institution had been supported on that occasion, for by the help of the liberal donations and subscriptions which had been announced the committee would be able to carry on the work of the Institution without anxiety during the coming year.

The Chairman, in proposing "The Architects and Surveyors," said that the builders owed much to the gentlemen of both professions. It was perfectly true that they (the builders) often found themselves completely in the hands of the architects; but, as a rule, those gentlemen performed their duties most properly and fairly. With the toast was coupled the name of Mr. Franklin, who, in responding, said he considered himself by no means an architect, although he did claim to be a surveyor. It was his decided conviction that the two professions were, and should be kept, entirely distinct, and he believed that that was an opinion which would be ratified by all builders.

Mr. Chappell, in proposing "The Committee and Stewards," spoke of the assiduity with which the committee of the Institution attended to their duties, and coupled with the toast the name of Mr. T. G. Smith, who, in responding, said that as some illustration of the way in which the committee performed their duties he might mention that when, at the beginning of the year, Mr. Fourdrinier offered to get up a theatrical performance an aid of the funds of the Institution, the committee at once guaranteed all the necessary expenses, and the result was that the entertainment brought in more than £100 to the funds of the Institution. More recently,

when the offer which had been referred to, came before them, eleven out of the required twenty donations of ten guineas each were promised by members of the committee.

Before leaving the chair, the President announced that he had received several kind letters from friends of the Institution, wishing him success on that occasion. One of them was from Mr. W. R. Rogers, of the firm of Cubitt and Co., who stated that when he was president of the Institution some years ago his firm offered one hundred guineas to its funds, provided nine other firms would give the like amount each. Now, Mr. Chappell had consented to be the president of the Institution next year, and if that gentleman could find nine firms who would give 900 guineas collectively, his (the chairman's) firm would give the tenth hundred guineas. Mr. Chappell said he accepted that challenge with pleasure, and would do his utmost to be able to claim the fulfilment of the president's promise. Personally, he might say that he should not be backward in doing his part.

SANITARY INSTITUTE OF GREAT BRITAIN.

EXAMINATIONS FOR LOCAL SURVEYORS AND INSPECTORS OF NUISANCES.

AN examination held by the Sanitary Institute of Great Britain, on November 3rd and 4th, eight candidates presented themselves. The following questions were set to be answered in writing on the 3rd, and the candidates were examined, viva-voce, on the 4th inst.

The Institute's certificate of competency as local surveyor was not awarded, but the Institute's certificate of competency as inspector of nuisances was awarded to Joseph Horrocks, W. Sortwell, and J. W. Witts.

EXAMINATION OF SURVEYORS—Nov. 3, 1881.

PAPER 1.—2 TO 4 P.M.

1.—State the conditions under which the discharge of sewage matter into streams is prohibited by the Rivers Pollution Prevention Act, and also the conditions under which such discharge is not prohibited by this Act. Explain what is the meaning of a "stream" under the Act.

2.—Is foul air more likely to be found in the sewers of a town or of a village? and why? What are the best means of preventing its formation?

3.—What are the relative advantages and disadvantages of pipe and brick sewers? How can the objections to pipe sewers be overcome? Illustrate your answer by sketches.

4.—How much sewage would pass in twenty-four hours through a sewer of 36 in. diameter, laid at an inclination which would give a velocity of 3 ft. per second, and what population would this sewer suffice for in a town with a public water supply where the rain and surface water, other than that from the roofs and paved yards of houses, is carried off by a separate system? Give your calculation in full.

5.—Draw the scheme of drainage you would suggest on the accompanying plans of a dwelling-house, and give sketches of the various traps you would employ, of the method of laying the drain and of its connection with the sewer, accompanied by a short description of the mode of executing the work you propose.

EXAMINATION OF SURVEYORS—Nov. 3, 1881.

PAPER 2.—6 TO 8 P.M.

1.—If asked to advise as to the water supply of a town, what are the chief points to which you would direct your attention, if the supply is to be derived

(a) From wells?

(b) From streams?

2.—Describe the construction of an ordinary rain gauge and the precautions which should be taken in fixing it. Give instances of the amount of annual rainfall in various places. What weight of water does one inch of rain on an acre represent?

3.—What materials are used for the construction of cisterns and water pipes, and what are the advantages and disadvantages of each?

4.—Explain what is meant by ventilation of rooms? How far does the size of a room affect the question? Given, a room 12 ft. by 10 ft. by 10 ft. high, occupied by three persons, what means of ventilation would you adopt? To what extent will they be efficient?

5.—Write a specification for the construction of a macadamised road, 40 ft. wide with 6 ft. foot-way on each side, across an estate on a clay soil, with cross section, and estimate of cost per foot run.

EXAMINATION OF INSPECTORS OF NUISANCES—Nov. 3, 1881.

4 TO 6 P.M.

1.—Mention the principal Acts relating to the Public Health, and state briefly their most important provisions.

2.—What is the order of procedure prescribed by the Sale of Food and Drugs Act in obtaining for analysis samples of articles suspected of being adulterated?

3.—Describe some simple means of ventilating sleeping-rooms which you think would be efficient. What do you consider overcrowding?

4.—What are the physical characteristics of good drinking-water?

5.—A house is found to be unhealthy; there are occasionally (not always) offensive smells, perceived both in the basement and in the upper rooms; what is the most likely cause of this, and how would you proceed to investigate it?

6.—How should the soil pipes, sink pipes, and overflow pipes of a dwelling be dealt with so as to prevent any danger to the inmates? What do you consider a proper fall for a 6 in. house drain?

7.—How would you proceed to disinfect a house in which a case of typhus fever or small pox had occurred?

8.—In the inspection of a slaughter-house, to what points would you specially direct your attention? What are the requirements of a properly constructed slaughter-house?

CHIPS.

The name of C. H. Payne, of Kettering, architect, appears in Tuesday's *Gazette* in the list of liquidations by arrangement.

The chief stone was laid on Monday of new buildings, and an extension of the hall of the Bakers' Company in Harp-lane, E.C. Bakers' Hall, which was burnt down during the Great Fire, was afterwards rebuilt, but was again destroyed, during the Thames-street fire of January, 1714, and the present hall was erected in 1719. The present additions are being carried out from the plans of Mr. Joseph Clarke, F.S.A., and Mr. Charles J. Shoppee, joint architects. Mr. E. Lawrence is the builder, and Mr. Merfield the clerk of works.

Memorial-stones were laid on Saturday week for new school-buildings at Cheadle Hulme, for the Manchester warehousemen and clerks' school. Messrs. W. and G. Higginbottom, of St. Anne's-square, Manchester, are the architects, and Messrs. Robert Neill and Sons, of Strangeways, Manchester, are the contractors.

The Hendon board of guardians last week adopted plans, by Mr. H. Saxon Snell, for additions to the workhouse, estimated to cost about £18,000 in execution.

At Tuesday's meeting of the Commissioners of Sewers for the City of London, a letter was received from the manager of Edison's Electric Light System, offering to light, free of cost, for two months, the Holborn Viaduct and Bridge, and its towers, by Edison's incandescent lamps. The letter was referred to the Streets Committee with power to act.

Mr. S. Brunson has been elected to the office of town surveyor of Northleach, Gloucestershire.

At the Manchester Diocesan Consistory Court on Friday, faculties were granted for reseating Trawden church, removing organ to west gallery, and forming a chancel; for enlarging the north aisle and vestry of St. Cuthbert's, Preston; for removal of pulpit to north side, and rearrangement of choir-stalls, &c., at St. Peter's, Oldham-road; and for internal restoration and alteration at St. Bartholomew's, Whitworth.

Princess Christian opened a Working Men's Club at Datchet, on the 7th inst. The building has been erected by Mr. J. Willis, from plans prepared by Mr. Stephen Wyborn, architect, Windsor.

In our report last week of the prize distribution at the Architectural Association, on p. 516, the competition in which no award was made should have been the Architectural Association medal, instead of, as stated, the Architectural Union Company's medal. The latter, given for measured drawings, was awarded to Mr. E. G. Dawber, a second prize being given to Mr. A. Hemingway.

We learn that it has now been finally decided to commence the Manchester Cathedral Restoration by replacing the old columns in the nave with new masonry. For these alterations or additions, it is understood, an application for a faculty will be made at an early sitting of the Consistory Court.

The town council of Hull have adopted plans, by Mr. Sharp, the borough engineer, for a pumping-station, to be erected near the Sir William Wright Dock, for the raising of the west district sewage; it will be provided with duplicate compound pumping-engines, each capable of raising 10,000 gallons per minute, with a lift varying with the tide from 20 ft. to zero; there will be three boilers, each capable of driving one engine. The estimated cost of the work, including a short railway-siding for supply of coal, and a new sewer-outlet into the Humber, is £10,000.

At a meeting held at Wroughton, near Swindon, it was decided to seek Parliamentary powers for constructing a tramway from the centre of Wroughton to a junction with the S. M. and A. line in Swindon. Mr. Edward Watson, C.E., who prepared the plans, stated that the cost of a 3 ft. single line would be about £5,000, and that if the gauge were 4 ft. 8 in. the cost would be £10,000; but they would obtain through traffic, and the earning powers would be increased threefold. It was decided to adopt the wider gauge, and to form a company.

Building Intelligence.

ARMAGH LUNATIC ASYLUM.—The works in connection with the additions and improvements at this asylum have been nearly two years in progress. Some portions are finished and in occupation. The remainder is drawing towards completion. To provide accommodation for over one hundred patients was the principal object of the work, and this was done by erecting four blocks of building, three stories high each, at extremities of present wings, those in front being similar to each other—one for males, the other for females. The chapel, a small, neat Gothic building, has been erected in the lawn in front, having a bell gable facing the principal entrance; it is built of perforated bricks from Belfast, with Dungannon freestone dressings, has open-timber roof, and its walls wainscoted, and is fitted up with pitch-pine benches. A great many further improvements have been made, such as provision for collection and storage of rainwater for washing purposes and sewerage, which includes culverting over 100 yards of the town sewer, which passed through the grounds, and was very offensive. It is in contemplation to erect a water-tower, and plans have been prepared for the same. It will be in the form of an Italian campanile, 90ft. high, having a cistern at the top, containing 12,000 gallons. The cost of the works will be about £20,000. Messrs. Collier Brothers, of Portadown and Dublin, had the contract. Mr. John Boyd, C.E., of Belfast, is the architect, and Mr. Robert Campbell clerk of works.

BELSTONE.—The little Dartmoor village church of Belstone, situate about three miles from Okehampton station, was reopened on Tuesday week. The church, dedicated to St. Mary, is a good specimen of the Early English style, is built of granite, with a square tower, and has a nave and south aisle. The porch was probably of the date of the 13th century, and, with the church, has long been in a state of ruin. Messrs. Hayward and Son, architects, of Exeter, were some time since consulted, and prepared plans. The nave and the south aisle have been roofed, the arches taken down and replaced, the floor tiled, the porch rebuilt, and the whole of the exterior and interior put in a state of thorough repair. The builders were Messrs. Petrick, of Hatherleigh.

CARLISLE.—Extensive additions and alterations have been made to the premises in English-street, recently purchased by Mr. J. Atkinson, draper, &c. The back buildings have been entirely rebuilt and the main front buildings have been gutted and remodelled. The alterations include a new shop front, in which large window space has been gained and added to the somewhat narrow frontage. The interior of the shop is effectively lighted by the lantern roof over a gallery on the first floor. The new premises, comprising shop, show-rooms, millinery saloon, workshops and workrooms, is now one of the most complete of its kind in Carlisle. The works have been expeditiously carried out in a satisfactory manner. Mr. T. Milburn being contractor for brickwork and masonry, and Messrs. Batey and Forster for carpenter and joiner's work, the remaining trades being executed by local tradesmen. The prismatic lights have been supplied by Messrs. Hayward Bros., the mosaic floor by Mr. Ebner, and the revolving shutters by Messrs. Clark, Bunnett and Co. The works have been carried out from the designs and under the superintendence of the architect, Mr. G. D. Oliver, of the firm of Hetherington and Oliver, of Carlisle.

ECCELES.—The New Town Hall, Eccles, was opened on the 3rd inst. It is of the Italian style of architecture. The principal fronts are faced with stock bricks relieved with masonry to the doorways and windows. The main entrance is in the centre of the front elevation, and over the same is the clock-tower. The accommodation on the ground-floor comprises board, committee, and waiting or ante-rooms, with offices for the clerk, inspector and collector, &c.; each are approached by spacious and well lighted corridors, laid with encaustic tiles. The first-floor contains a public-room to seat 1,000 persons (with gallery at one end) approached by a well arranged staircase with spacious landings affording access to retiring and ante-rooms; additional staircase affords separate access to the platform and retiring rooms adjacent thereto.

The principal rooms are warmed by hot-water apparatus, the remainder have open fireplaces. In the basement rooms are provided for the caretaker, also coals, heating apparatus, &c., and a strong fire-proof room with separate entrance. The building has been erected by Messrs. Moore and Sons, builders, Eccles, at a cost of about £1,600, under the superintendence of the architect, Mr. John Lowe, F.R.I.B.A., Manchester.

EXMOUTH.—On the festival of All Saints, the mission chapel dedicated to St. Saviour was opened for Divine service. The chapel is a simple structure of brick, with slated roof, and will accommodate about 185 people. It has a nave, south transept, apsidal chancel, and vestry; and the chancel can be shut off by a screen with movable shutters, if the nave is required for school purposes. There was a west porch on the design, but this had to be omitted owing to the local board requiring the ground for widening the road, but a lobby is to be put on the inside to prevent draughts. The whole of the work has been completed by Messrs. Redway, Son, and Carter, of Exmouth, from the designs, and under the superintendence, of Mr. R. Medley Fulford, architect, of The Close, Exeter.

HEDON.—The fine parish-church of Hedon in Holderness was reopened on Wednesday week after the restoration and completion of the tower. The floors of the clock-room, bell-room, and belfry have been relaid and the windows fitted with new oak weather boards, this part of the contract having been carried out by Mr. Reynardson. The masonry of the tower has been restored by Messrs. Wilson Brothers of Hull, and it is now finished by a pierced parapet and pinnacles, rising to a total height of 130ft.; the square of tower at base is 47ft. The bells have been rung by Mr. Walker, of Hull, and the chimes, which were given to the town in 1662, have been put in going order by Mr. McKenna, of Hedon. The total expenditure has been about £7,000.

LONDON.—St. Peter's Church, Vere-street, Oxford-street, has been closed for about three months, during which time it has been decorated and re-seated in oak, with new carved oak pulpit, lectern, &c., and was reopened on Sunday, the 6th inst. The whole has been designed by, and the work carried out under the superintendence of, Mr. James K. Colling, architect. The execution of the oak-work and carving was entrusted to Messrs. Cornish and Gaymer, of North Walsham, Norfolk. The decoration to Messrs. J. & J. King, of Norwich, and the glazing of the side windows to Messrs. Pepper and Co., of the Easton-road. The east window has been filled in with stained glass by Mr. Burne Jones. The church externally is a plain brick structure of very unpretending appearance, but internally it is divided into nave and aisles, having an enriched plaster ceiling supported on Corinthian columns. The architect of the building was James Gibbs, who also designed St. Martin's-in-the-Fields, to which church St. Peter's bears a considerable resemblance, although upon a smaller scale. The total cost of the work was about £2,000.

LOW FELL.—Last week several memorial-stones of a new Wesleyan chapel which is about to be built at Low Fell, Gateshead, were laid. The building will be in the Gothic style. The material used for its construction will be stone, and an historical interest will attach to it from the fact that in a prominent position in one of the walls will be placed the old stone from which John Wesley preached in the neighbourhood of the present chapel at the Fell, with a suitable inscription cut upon it. The chapel, as at present planned, will seat about 500 worshippers, but there is a space left in the rear by which it can be extended to accommodate about 300 more. Internally, the edifice will have a nave and two side-aisles. Galleries will run round three sides of the building. The estimated cost of the whole scheme is about £3,500. The builders are Messrs. Greason and Stockdale, of Gateshead. The chapel has been designed by Mr. J. J. Lish, architect, of Newcastle-on-Tyne.

PHILADELPHIA, U.S.—The corner-stone of a new Roman Catholic Church was laid upon the 16th ult. by the Bishop of Harrisburg. The edifice will be dedicated to St. James, and is well situated at the south-east corner of 38th and Chestnut-streets. Of Gothic character the general plan consists of a nave with side aisles,

intersected by a transept, the apsidal termination of the nave forming the sanctuary or altar recess; around this apse a corridor, or more properly speaking, an ambulatory passage, runs, divided from the altar recess by an arcade of red granite columns with white marble base and capitals, with pointed arches and groined ceilings. The sacristy, on the south-east corner of the building, will be octagonal in form, and the south-west sacristy is circular on the plan. The confessionals are built in the walls, recessed. The facade on Chestnut-street has a frontage of 78ft. of bold design, consisting of two massive towers, flanking the central doorway, 32ft. in width and 40ft. high. The architect of the building is E. F. Durang. It is only proposed to erect the basement this season, but to roof the edifice in next year.

SEVEN DIALS.—A new mission house for the Seven Dials district of St. Giles' parish has been erected in Shorts-gardens in connection with the London Diocesan Home Mission. The work in this place (which has existed for more than 20 years) has been hitherto carried on in a small and inconvenient room, divided from the street by a bakehouse attached to a baker's shop adjoining, and was very unhealthy through defective drainage, badly lighted, and much out of repair. This has been all cleared away with the exception of the side and back walls, and the new building now extends the whole length of the site, being about 80ft., and has a frontage to the street of simple First Pointed character in stock bricks, the arches and jambs being of red bricks and Bath stone. The design consists of a main gable finishing the end of the open-timbered roof and a bell gable at the side. The building is well lighted from the roof by dormers between the principals. The drainage has been entirely reconstructed and the premises made thoroughly healthy. The architect was Mr. W. Milford Teulon, of 18, Upper Woburn-place, and the builder, Mr. Andrew Killby, of Appold-street, Finsbury, who has done his work excellently well.

CHIPS.

The Mersey dock commissioners decided on Thursday week to seek Parliamentary powers to construct a double line of overhead railway from one end of the docks to the other.

The upper part of the spire of Honeybourne Church, near Pershore, which was recently injured by lightning, is being reconstructed under contract by Mr. Frith, builder, of Coventry.

The parish-church of St. Lesdegar, at Wyberton, near Boston, has been reopened, after restoration from the plans of Mr. G. G. Scott, M.A., F.S.A. The builder was Mr. S. Sherwin, of Boston.

The foundation-stone of an addition to the Roman Catholic church at Springburn, near Glasgow, was laid on Tuesday week. The work will cost £3,000, and is from the designs of Messrs. J. L. Bruce and D. Sturrock, I.A., of Glasgow.

The annual distribution of prizes to the students in the Science and Art Institute at Walsall, took place on Wednesday week. The report showed that in art six Queen's prizes and fourteen certificates had been gained at the examinations; and in science, twenty-five Queen's prizes, twenty-five excellents, and fifty-two proficiency certificates.

The work of re-seating the parish-church of North Elmham was commenced last week. Messrs. Cornish and Gaymer are the contractors.

A large vestry-hall and Bible class-room, added to Christ Church, Swansea, was opened on Thursday week; Mr. Thomas White, of Swansea, was the builder. Heating apparatus on the hot-water system is now being placed in the same church by Mr. John Legg, contractor, of Swansea.

At a vestry meeting held at Kenninghall, Norfolk, on the 3rd inst., it was resolved to take steps for restoring the parish-church, and a committee was appointed for that purpose.

The Clarkson memorial at Wisbech will be unveiled by the Right Hon. the Speaker to-day (Friday). The statue is of white Ancaster stone, and has been carved at the works of Messrs. Farmer and Brindley, Westminster-bridge-road, S.E. It stands beneath a Gothic canopy, and represents Thomas Clarkson in a standing position, with a scroll in one hand and a slave's fetters in the other. In the pedestal are four panels of red Mansfield stone; one is occupied by the inscription, and the others contain bas-reliefs of Wilberforce, Granville Sharpe, and a slave. The late Sir Gilbert Scott, R.A., was the architect, and the cost has been over £2,000.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—The annual meeting of this Association, for the opening of session 1881-1882, was held on Tuesday evening, the 8th inst., in the library at Queen's College. The president, Mr. Jethro A. Cossins, occupied the chair, and there was a good attendance of members and visitors, including Messrs. J. G. Bland, H. F. Talbot, G. F. Hawkes, R. B. Morgan, J. L. Ball, J. P. Osborne, W. Henman, T. Jones, W. Wallis, J. William Tonks, W. H. Kendrick, of West Bromwich, H. H. McConnell, and F. E. F. Bailey, of Walsall, Fred. G. Hughes, honorary secretary, &c. Apologies for non-attendance were received from Messrs. George Inghall, W. Hale, W. Martin, E. Pincher, E. Wood, H. Clere, Aston Webb (president of the London A. A.), and others. The annual report was read by the secretary, and was adopted on the motion of the president, seconded by Mr. Kendrick. The balance-sheet was read by the treasurer, and was approved on the motion of the president, seconded by Mr. Osborne. The president then delivered an address, in which he dwelt chiefly on the subject of street architecture. At the conclusion, a very hearty vote of thanks was accorded to Mr. Cossins for his very excellent and interesting address, on the motion of Mr. McConnell. Messrs. Morgan, Tonks, and Henman, spoke in support of the motion, and after the president had replied, the meeting terminated. A large collection of drawings was exhibited on the walls, including all the principal class designs, and a numerous selection of sketches by Mr. John Cotton and others, which were kindly lent for the occasion.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The opening meeting of the present session of this Association was held last week. Mr. John McLachlan, president, read a paper entitled "Notes on Some Old Edinburgh Architects." In the outset, he remarked that it was a subject of regret that although the city owed a deep debt of gratitude to her architects, their names and memorials had been treated with scanty regard. They would search far in Edinburgh even in classes far higher than of labourers to find any one who could tell them anything of the designer of St. Giles' Crown, or Holyrood, or even Heriot's Hospital. So rapidly did the memory of architects here depart that, taking these three buildings—of St. Giles' spire nothing was known; of Holyrood antiquarians could tell them something; and of the third—Heriot's Hospital, only 200 years old, disputes were rife among the learned as to the very personality of the architect. These facts, he submitted, were humiliating to our national pride. Going yet farther back into the past than the end of last century, or, roughly speaking, the commencement of the building of the New Town of Edinburgh, Mr. McLachlan referred in detail to Mr. James Craig, who seemed to have enjoyed a large and lucrative practice in designing the various buildings in the New Town, which were erected in the carrying out of his feuing plan; to Robert Adam, who far surpassed Craig in the extent and variety of his practice, his works being scattered broadcast over the face of Scotland even to this day; to David Stevenson, the celebrated engineer, who designed the new approach to the city by Regent-road and Waterloo-place; to Archd. Elliot, who designed the Calton Jail, Regent Arch, and County Buildings; to Thomas Hamilton, who designed the Burns Monument on the banks of Doon, the High School of Edinburgh, the present access by George IV. Bridge and Johnston's terrace to the centre of the city from the south and west, the Royal College of Physicians, and the Burns monument on the Calton-hill, was one of the principal founders of the Royal Scottish Academy, and architect of many of the Free churches erected immediately after the Disruption; and to William Henry Playfair, probably the architect who had buik'd most largely in the public eye in this century and in this country.

The Kidderminster Board of Guardians received last week a report from Mr. G. Morton, architect, of South Shields, as to the proposed rebuilding of the workhouse. Mr. Morton showed three alternative plans, two for rearrangements on the present site, and estimated to cost from £18,000 to £20,000; the third for new house and school on first site at an estimated cost of £30,000.

"To a practical man with a taste for mechanics, and the bump of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Architect*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 3s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 35s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—H. B. and Co.—F. H.—C. Bros.—M. R. Co.—T. R. and Son—H. and R.—B. S. Co.—A. W.—H. W. and Son.—E. E. C.—P. Broz.—D. H. and J. N. M. (Both at Batsford's, 52, High Holborn, if anywhere.)

"BUILDING NEWS" DESIGNING CLUB.
S. R. C. (There is no entrance fee or subscription to join the club.)—N. M. B. (We have noted your motto. The staircase is included in the dimensions given.)—T. B. A. (Small sketch or perspective is admissible, and a competitor can send designs for both subjects. The names and addresses of all competitors are required to be appended to the back of every drawing sent in.)

Correspondence.

DUBLIN MUSEUM COMPETITION.

SIR,—What your correspondent "Fair Play" asks is doubtless desirable. May I point out something equally so, if not more?

It is that the committee of selection, having chosen the specified five sets of drawings, should have no knowledge whatever of the subsequently disclosed mottoes and authors of the same, but that such disclosure should be made by an again independent person. It is obvious that once associated, the designs will on the next occasion be at once recognisable, and although the committee are then only to report on them (the treasury selecting) the greatest amount of independence would be obtained by the following of this suggestion.—I am, &c. L. R.

TESTS FOR TRAPS.

To the Editor of the BUILDING NEWS.

SIR,—You will, of course, remember that recently not a little discussion has taken place as to the value of the various closet-traps, and that there are certain of them that I have advocated; also that, in furtherance of my ideas, I have attended various experiments with a view of testing the actual value of each individual trap.

The result of these experiments I have duly reported, and as accurately as possible; but as some members of the trade seem to doubt (not improbably from reasons especially of their own) the accuracy of my reports, I beg now to inform them that on Saturday, Nov. 19th, at 3 p.m., a

committee of practical plumbers have arranged to meet and finally test the various traps. Any interested members of the trade can attend, and I trust that you will ventilate the matter as much as possible.—I am, &c., P. J. DAVIES.

SIR,—Referring to Mr. Davies' experiments, some of the conditions of which are correctly shown on page 540, allow me to say that, to enable your readers to fairly estimate the value of the results given, it is absolutely necessary for them to understand fully the whole of the conditions under which the experiments were made. Now, this page 540 does not give: the basins are there shown fixed upon the top of the traps, and I was under the impression that this was a fair representation when I wrote my letter, which appears upon page 575. On Wednesday last I paid Messrs. Pullen and Davies a visit at Kennington, and then found that, instead of the basin setting upon the traps as shown, there was in the case of the round P a space of 18in. between the plug in basin and the waterline of trap. Now, with this arrangement, this happens to be the vital point, for according to the length of this space is determined the safety or otherwise of the trap.

Under these circumstances, I must ask your readers to suspend their judgment until next week, when I will do my best to fully explain this point.—I am, &c., DANIEL EMPTAGE, S.E.

Dane Hill Sanitary Works, Margate, Nov. 7th.

BRIGHTON HEALTH CONGRESS AND DOMESTIC AND SCIENTIFIC EXHIBITION.

SIR,—A paragraph in your last issue referring to the forthcoming Health Congress and Exhibition, at Brighton, is calculated to mislead intending exhibitors, and as it also reflects rather unwarrantably on the good judgment of the committee, we do not think it right to let it pass unnoticed.

The rates of payment for the exhibition of drawings, when coupled with the powers of rejection reserved by the committee (explained in the circulars already sent you), are a guarantee that commonplace productions will not be hung. It is, therefore, scarcely within the limits of good taste, to say that we shall "exhibit probably in the most prominent position thus paid for, works devoid of any merit at all."

As a justification for making the proposed charge, we may explain that there does not appear to us any sufficient reason for placing architects upon a better footing than other classes of artists, of whom very many in different departments of art are preparing to exhibit.

Whilst the exhibition is intended to benefit the Brighton School of Science and Art, there are doubtless many less interested motives for its promotion; but it is probably equally true that each exhibitor, however kindly disposed towards the object of the Exhibition, has some small residuum of more personal interest in view.—We are, &c.,

CHAS. E. CLAYTON } Hon. Secs., Art and
JOHN GEO. GIBBINS } Industrial Dwellings
Sections.

Royal Pavilion, November 9th, 1881.

[We simply doubted, and we still doubt, whether any architects of good standing were likely to exhibit on the terms offered by the committee. The result will probably show that we are right, and that the committee, in their inability to distinguish between architects and other exhibitors, have made a mistake.—ED. "B. N."]

A new sessions court was opened at Newent last week. It is Domestic Gothic in style, and is erected in red brick, with black brick bands and arches and local red tile roofs. The joiners' work is of varnished pitch-pine. The building comprises magistrates' rooms, solicitors' rooms, clerks' rooms, three cells and guard-room, and a public court-room, heated by a Shorland stove, and having at the south end a stained-glass window by Dauncey, of Gloucester, representing Justice with the scales. Messrs. Medland and Son, Gloucester, were the architects; Messrs. Jones Brothers, of Newent, the contractors, and Mr. Phillips the clerk of works.

A new wrought-iron foot-bridge, of 90ft. span, has lately been erected by the Corporation of Stamford over the river Welland, to replace one destroyed by the great flood of July, 1880. The total cost, including entirely new abutments and approaches, is between £700 and £800. The work has been executed from the designs and under the superintendence of Mr. J. B. Everard, C.E., of Leicester; the contractors being, for the builder's work, Mr. C. Hinson, of Stamford, and for the ironwork, Messrs. Dawson and Nuneley, of Hunslet, near Leeds. Mr. T. J. Ward, of Stamford, has efficiently filled the post of clerk of works.

Intercommunication.

QUESTIONS.

[6760].—**Sp. G. and Crushing Weight of Stones.** What is the specific gravity and crushing weight of the following stones, viz.:—Dumfriess, Corsehill, and Red Mansfield?—*VERITAS.*

[6761].—**Baths.**—Having a hot and cold water bath to put up, would some of my fellow-readers kindly inform me as to the sizes of cylinders and other particulars appertaining to same?—*R. SPOON.*

[6762].—**Geometrical Conics.**—Would some one mention the name of a cheap treatise on pure geometrical conics, such as would meet the requirements of that section of science and at examination in mathematics, fourth stage, which treats of that subject?—*C. S. S.*

[6763].—**Clay Ballast.** Will any reader kindly give me practical information as to buying clay ballast for concrete, mortar, &c.?—*M. VOS.*

[6764].—**Chimney.** I have asked several architects the following question, viz., of a chimney 15 yards high, with 3 ft. outlet at the top, tapering all the way inside in proportion to the outside, and one 10 yards high, with an inner casing 3 ft. dia. from bottom to top, which will give the best draught? I have been often told that the one with inner casing is much better. If this is correct, is the column of heated air heavier or lighter in the case of uncased chimney? I hope some of your correspondents will be able to answer the question for the benefit of many of your readers. A YOUNG BUILDING.

[6765].—**Glazed Earthenware Flue Lining.** In common with, I imagine, most other architects, I have lately considered this essential to good work. I am, however, informed by an intelligent and trustworthy contractor, who was formerly clerk of works to an eminent architect, that it proves, in a few years, a source of much annoyance, owing to the soft falling from the glazed surface in summer, whenever the least dampness occurs, and that the said eminent architect has, on that account, left off specifying it. Can any reader corroborate or contradict?—*SPOON.*

[6766].—**Heating Chapel.**—I want to construct a chapel with school beneath. How shall I heat the chapel the cheapest possible way? Answer to the above will oblige—*A. B. M.*

REPLIES.

[6760].—**Woodcarving.**—It is impossible in a short paragraph to give "Z. D." many useful hints in regard to wood carving. Proficiency therein is only attained by a lifetime of application upon the top of some natural talent and inclination for that particular sort of thing. Addis's is the best. A few dozen chisels and gouges, a bench screw, and a holdfast are all the appliances a woodcarver relies upon, and his whole "kit" does not cost more than a couple of pounds or so. "Z. D." had better make friends with some good woodcarver, and get practical lessons from him.—*HARRY HEMS.*

[6763].—**The Scott Monument.**—As to Sir Walter Scott's beautiful monument in Princess-street, Edinburgh; in December, 1835 the committee offered three premiums of 50 guineas each for designs for a national monument to this great author. The proposed expenditure was £50,000. In response, 54 designs were sent in, and the prizes were awarded in the following order:—To Mr. Birkman 1st, to Messrs. C. Fowler and R. W. Sievier 2nd, and to designs under the nom de plume of "John Morvo" 3rd. None of the plans were altogether satisfactory, however, and fresh designs were asked for. In this second competition "John Morvo" was the successful artist. It then appeared that the owner of this motto was a George Knapp, a journeyman joiner, residing in Canmies-place, Edinburgh, who, being early in youth impressed by the beauties of Roslyn Chapel, had ploddingly learnt drawing and perspective, and had become not a little expert in architectural drawing. Knapp's design was ultimately accepted in March, 1838. It was described at the time as "of beautiful proportions, in strict conformity with the Abbey, from which all its details are derived." The foundation-stone was laid Aug. 15, 1840. The contractor was Mr. David Laing. Mr. Knapp personally superintended the works for about two years; then, said to narrate, one dark foggy night, whilst on his way home to Morningside, Knapp missed his way, and, falling into the Union Canal, was drowned. He was buried at St. Cuthbert's cemetery, where a monument marks his grave. After this Mr. Bonar, the ill-fated artist's brother-in-law, carried the work on, and very faithfully completed his task. The final expense was £16,151 7s. 11d. Of this sum the following items may be recorded:—The cost of the foundations, which took down 52 ft. beneath the surface, was £1,574 18s. 6d. Mr. David Laing, the mason, was paid £9,512 18s. 3d. Sir John Steell, B.S.A., for the marble statue, received £2,000; the architect's fees were £2,571 18s. 6d.; and the clerk of works' salary amounted to £52 16s. 4d. The inauguration of the monument took place on August 15th, 1843.—*HARRY HEMS.*

[6765].—**Girder.**—Thinking Mr. McLachlan for information already given, I have submitted full particulars of girder. Draw a line diagram of the lattice girder

here given, showing the parts which should be designed to resist compression by thick lines, and those to resist tension by thin lines. The girder to be uniformly loaded from end to end at top. Which of the braces will be subjected to the greatest stress, and how is it arrived at?—*H. D.*

[6731].—**Old Crosses in West Cornwall.**—"M." opens an interesting topic when he refers to the origin and purpose of old Cornish crosses. By his reference to St. Clether and Launceston, I see he has been amongst the crosses of East Cornwall. The original query definitely confined itself to West Cornwall, and in my recent reply I kept myself to that particular region. Of course, what applies to one part of the county, in a general way, is applicable to another. The Tau cross, with the circular head, is altogether a Cornish feature. Cornwall is a very old county. Missionaries came over from Ireland, sent by St. Patrick, in the middle of the 5th century, and St. Petroc, the celebrated Cornish saint, studied under St. Patrick in Ireland. Conan was Bishop of Bodmin in 939; A.D. The last Cornish bishop was Burghold, in A.D. 1010. The old Cornish crosses were undoubtedly erected under various circumstances. At such places as Penzance and Llanidloek, they seem to mark the site of ancient and now destroyed churches. Those on the highways were endposts to religious houses or oratories, and were also praying-places. Amongst the wild moors, they must have been very useful, for there, nothing and nobody existed to direct the traveller on his way. But that they were wholly for secular uses and more guides for pilgrims, is upset by the fact that they also occur in churchyards. Stepping out from West into Mid-Cornwall, just for the sake of a fresh illustration, I may mention that at Lanivet, near Bodmin, there are two exceedingly fine old Tau crosses. These are in a particularly perfect state, and are both within a few yards of the ancient parish church. Many old chapels have been wholly destroyed, but crosses exist in their neighbourhood, and it is very possible that these latter were originally erected as incentives to devotion; as well as mute appeals to the passer-by to turn on one side, and give of his belongings to the praying folk who lived at the baptisteries or chapels in question. Thus, at St. Clare, St. Clement's, St. Paul, Trewell, Ludzvan, St. B. adget, at Lanyon; Triggamin, Higher Triggamin, Bunnan, Vellansey, Rose-an-Cr-wz, Tre-wanick, and at many other places where there are crosses, records of old ecclesiastical buildings having existed are preserved. Of course, most of the ancient wells were supposed to possess marvellous properties. At the side of Madron well, which lies on the moor, a mile or so from the church, is a stone seat, formerly known as St. Madron's Bed. Madron is spelt Madron in some old manuscripts. It was upon this that impotent folk reclined when they came to try the cold-water cure. There was also a chapel, about 100 yards away. It was partially destroyed by Cromwell, but the ruins still remain. Those who were benefitted gave alms to the poor and to the church. This was done down to the middle of the 17th century. Besides the old crosses of West Cornwall, one must not overlook the monoliths that are scattered all over the face of the county. These seem to be sepulchral pillars of an even earlier date than the crosses. Some are inscribed, as, for instance, the Men Scrya stone, at Madron, and another at Bant-y-ridge, Gwyl, At Sander, St. Eilian, St. Just, Lelant, Sennen, Paul, and Munch, there are some fine monumental pillars. The two at Bolet or St. Eilian are the largest; one is 15 ft. high, the other 13 ft. high; and handily is yet another stone measuring 10 ft. The smallest of those named above is the one at Trevar, in Sennen; it is not more than 5 ft. high. Most of the Cornish crosses and stones referred to are of coarse moorland granite; but a few, if I mistake not, are of porphyry, or of the local elvan. I believe that the date of these upright stones—certainly the inscribed ones—is about the early part of the 4th century.—*HARRY HEMS.*

[6733].—**Window Tracery.**—I know of no work on tracery above, except Bilings' "Pocket of Form" and that was brought out only to show the multitude of designs which could be produced for the simple geometrical figure of two equal circles inscribed in a large circle, the result being that it can in no sense be considered a treatise on tracery; any student of it would learn much thereby, though some of the designs may be open to objection on the score of beauty. On the other hand there are few works in Gothic architecture which do not give designs of tracery, many of which are details to large scale with the centres and joints distinctly marked; for instance the works of Fugate, Sharpe, Coling, Bowman and Crowther, besides others. None of these can be called cheap. They are mostly to be had of Mr. Batsford, High Holborn, London, W.C.—*HUGH McLACHLAN.*

[6741].—**Mounting Engravings, Tracings, &c.**—Scrap books of all sizes, descriptions of paper and binding are to be had and I expect that everyone wishing to purchase could be suited. For quick mounting of small engravings on paper as used in the journals, I would recommend fastening down the corners only with thin gum; the same might be adopted with tracings on paper. If on thicker paper or linen, thicker gum would be required. When gum is unsuitable, small cuttings in the pages of the scrap book itself for inserting the corners is a good plan, of course the material so cut must then be stout, this plan is generally seen at places where architectural and other photographs are sold, for anything so simple can be easily withdrawn. Starch is used for mounting photographs. I have not used it myself, but should consider it much preferable to paste; when either of these are used I would prefer covering the whole of the back instead of the edges only.—*HUGH McLACHLAN.*

[6742].—**Compressibility of Air in Sewers.**—I do not think it can be calculated how long it would take before the air would be disturbed in the lower end after the opening of sluice or how far the water would first travel; these in my opinion would depend quite as much on the density of the air inside the sewer and on the state of the atmosphere as on the fall and diameter of pipe. Generally I believe "Sanitation" is right, the second case would in a great measure depend on how fast the water flowed into the pipe, the air being only able to escape at the top where there was a vacuum, the water driving the remainder before it. If the water were allowed to be run through with the pipe only half full, little or no good would be done, the first result would be to compress in the upper part of the sewer all or nearly all the air which occupied it and which after the escape of the water would occupy its former position. To change the air drive out what was in it, when fresh would rush in to occupy the vacuum. I would not use gullies, but ventilate sewers by direct openings in the crown of the roads.—*HUGH McLACHLAN.*

[6745].—**Fines.**—I have understood that this would in great measure depend on the wording of the conditions, it could not be enforced as a "fine," but as "liquidated damages" where damages for non use of the building could be proved, and to the amount lost or likely to be lost by such non-use, which may be less but can in no case be more than the sum named in the conditions.—*HUGH McLACHLAN.*

[6746].—**Architect's Account.**—An architect is not usually called upon to supply a detailed bill of extras and omissions to a client, though such should be prepared. I do not think an architect can be compelled to furnish detailed bill to his client, certainly not with builders' prices, though there would be no objection probably in his doing so. An employer, at least, has the right to ask for an abstract of the accounts.—*G. H. G.*

[6747].—**Thatched Churches.**—Your correspondent will find not one, but dozens, still existing in Norfolk. Turn to p. 611 in your present issue, and he will find a paragraph respecting a new thatch roof to Thurston Church, Norfolk.—*CHAS. E. READ.*

[6747].—**Thatched Churches.**—I have one in my sketch-book unnamed. I think it was visited in the A. A. excursion, Norwich, 1884, and either at Frunch, Knapton, or Edington. I remember it was a very desolate, out-of-way place, and this church had a truncated unfinished octagon tower at the middle of the west end, rising in a clumsy fashion from a rude unbuttressed square base. Some more accurate and methodical excursionist will certainly give "G. C." information as to this church.—*T. DREW.*

[6747].—**Thatched Churches.**—The following churches have thatched roofs:—Coveney, Cambridge-shire; Tytshall (chancel only), Norfolk; Ingworth (nave), do.; Thurgarton, do.; Trimmingham (chancel only), do.; Paston, do.; Riddington, do.; Ormesby, do.; Norwich St. Ethelred, do.; Pakenhall, Suffolk; Middleton, do.; South Cove, do.; Fritton, do.—*FRED. J. FREEMAN.*

[6747].—**Thatched Churches.**—These are most common in Eastern counties. I recently did work at Salhouse Church (spelt Salhouse in the parish register, I observed), near Norwich, under Mr. John Oldrid Scott, M.A. There the roof was an old thatched one. The nave roof has just been stripped of this, and a new one of English oak put up. This is covered by reeds 15 in. thick, a most conservative and interesting restoration. The building was reopened upon Nov. 1st. There are churches at Eaton, Ingworth, Thurgarton, Trimmingham (chancel), Little Melton, Marlingford, Tytshall, St. Margaret (chancel), all in Norfolk, with thatched roofs. In Suffolk may be recorded those of Pakefield, Middleton, North Cove, South Cove (nave only), Fritton, Ashby, The Net-ham, Sapiston, Rushmere, Kingsfield, Hopton, Icklingham, Eriswell, Coney Weston, Barham, and Barnby. Coveney Church in Cambridge-shire is thatched. In another part of England is Rotherham Church, Cheshire, with a thatched nave. All the above are, or were until recently, examples of thatched churches. Restoration has lessened the number that existed a quarter of a century ago considerably. Paston, Riddington, Ormesby, Norwich, St. Ethelred, and Metford are Norfolk churches that used to be thatched, but which, if my memory serves me rightly, are now roofed in the ordinary way. Of course, the old custom of strewing the church floors with rushes was once very general. It was not uncommon during the beginning of the present century. The practice is, perhaps, obsolete now. The last place I ever heard of it being in force was at Holt Church, near Wrexham. There until the restoration some six or seven years since straw and rushes were regularly used as a protection for the feet against the damp floor.—*HARRY HEMS.*

[6749].—**Commonplace Book.**—A commonplace book is a very desirable thing to keep. The plan I adopted for some years was to get a thick quarto or smaller size, and note-book with a large index, the only objection to which was that certain blanks would invariably be left and other spaces quickly become filled up. I have since adopted an ordinary manuscript book, inserting any notes or cuttings in consecutive order, and indexing at intervals. A better plan would be to have a thick case made to hold a few quires of paper simply kept in by cords, by which arrangement a classification could be observed the sheets on one subject being put in proper order as they were written. After all, a method may become so irksome as to make the trouble of keeping notes an encumbrance upon one's time; for this reason, the simpler the method is the better and more likely it is of being kept. The value of methodising one's reading and thought cannot, however, be over-estimated. Having kept a commonplace book for some years I can speak of the value it has been. As one's reading and experience extends, the earlier collections become of less value. Although I seldom refer to my old note books, the habit of "abstracting" or "loading down" matter has been of service. It tends to make the student sift for himself the value or truth of the authors he reads, to analyse facts, and to systematise his own knowledge. For this reason I have never regretted having taken the labour, and the practice it affords in precise writing has been of great service to me.—*G. H. G.*

[6750].—**Removing Oil Stains from Paper.**—Place a piece of clean blotting paper on the stained drawings, &c., and apply a hot iron. I think you will find that this is the most effectual way of removing them.—*FRED. J. FREEMAN.*

[6751].—**English Buildings Previous to the Conquest.**—The buildings now existing which were erected previous to the Conquest are few, as most of them were entirely constructed of timber. Mr. Parker, in his "Glossary of Architecture," says:—"The scant and uncertain reference to special buildings leaves it very difficult to apply definite dates to the few existing remains which we have of buildings before the Conquest. Even in the cases of Jarrold and Monk's Wearmouth, where we have more historical data than usual, there is some difficulty in saying what part of the work should be assigned to Benedictine. At both the churches there are considerable remains of moulded balusters, which probably fulfils the description by Bede, that the churches were built *more romanis*. How far and how much of the walls were restored after the fire, and destruction on account of the ravages of the Danes, leaves it difficult to

lay down any laws as to the character of the masonry itself of this period. But for the most part all that can possibly belong to this date is of very coarse and irregular rubble-work, with rather irregular Ashlar stones used for the corbels, and in the case in point the stone of the neighbourhood and the circumstances attending their history have to be taken into account before referring to them as a type of the usual building of that time. Of nearly the same age, that is, before the close of the seventeenth century, are probably the crypts of Hexham and Ripon, all that remain of the churches founded there at that time." The doorway in vaults under the dormitory at Westminster; a building at Deerhurst, and the remains of a church at Bradford-on-Avon (which is close to the large twelfth-century church) are thought to have existed previous to the Conquest; but, as Mr. Parker says, we have no certain data for differentiating the building actually completed before the Conquest and that completed afterwards. —FRED. J. FREEMAN.

[6752.]—Zinc Roofs.—The Vieille Montagne Co.'s zinc is a good description. For flats, No. 16 ought to be used, or 25oz. zinc. Iron nails must not be used, and the sheets should allow free expansion at the joints by rolls or laps. The rules of the Vieille Montagne Zinc Co. will assist "Zinc."—G. H. G.

LEGAL INTELLIGENCE.

EMDEN v. D'OYLEY CARTE—(Court of Appeal.—Before the Master of the Rolls, and Lords Justices Baggallay, Brett, and Lindley.)—This action was brought by Mr. Walter Emden, an undischarged bankrupt, claiming remuneration as an architect, and damages for wrongful dismissal, and other relief. On the application of the trustee in bankruptcy for an order substituting him as plaintiff, Mr. Justice Fry held that the Trustee was entitled to the remuneration and damage claimed, and added the trustee as co-plaintiff. This order was affirmed on appeal. The defendant had, in delivering his statement of defence, paid £360 into court, though he did not admit the plaintiff's right to anything. The original plaintiff's solicitor in the action, Mr. Tudor, took out a summons asking a declaration that he was entitled, under the Attorney and Solicitors' Act, 1860, to a charge on the £360 for his taxed costs, charges, and expenses of, or in reference to the action as the plaintiff's solicitor, alleging that the £360 was "property recovered or preserved" by means of the action. In the court below, Mr. Justice Fry held that the £360 was not "property recovered or preserved" to the trustee, inasmuch as the action was brought with the view of obtaining the money, not for the trustee, but for the bankrupt, consequently the solicitor was not entitled to any charge. The solicitor appealed. Mr. Cookson, Q.C., and Mr. Beddall, for the appellant. The application was resisted by Mr. J. Pearson, Q.C., and Mr. Turner on the part of the trustee. Their lordships reversed the decision of the court below; but in allowing the charge, they limited it to the costs which had been incurred down to the time when the trustee intervened.

EXTRAS.—BRIDLINGTON CEMETERY ARBITRATION CASE.—Sir Henry A. Hunt, the arbitrator in the case of Brown v. the Bridlington Burial Board, has just made his award in the arbitration case between the parties. The plaintiff, John Brown, builder, claimed £6,873 17s. 3d. over and above his contract for erecting two chapels and a keeper's lodge at the Bridlington cemetery. The burials board offered £1,665 in settlement, but Sir Henry Hunt has awarded him £3,058. The amount of the original contract for erecting the cemetery buildings was £3,808; but in addition to that sum the board paid him £992 for extra works, so that with the amount awarded by the arbitrator the total amount paid is £7,858.

IN RE GEORGE DAY.—(London Bankruptcy Court.—Before Mr. Registrar Hazlitt.)—This debtor has filed a petition for liquidation, describing himself as of Whitechapel-road, and of Hol-lington, St. Leonard's-on-Sea, builder and contractor. His debts, secured and unsecured, are estimated at £60,000.

STATUES, MEMORIALS, &c.

CLEOPATRA'S NEEDLE.—All the various additional art decorations which have been in course of preparation in connection with the obelisk on the Thames Embankment are now finished. The second colossal bronze sphinx will leave the works of the engineers and contractors at Pimlico for erection immediately, the first being already in position, and as soon as the fixing of the ponderous mass of metal is arranged, each figure being about 19ft. long, 6ft. wide, and 9ft. high, the hoarding will be removed. The additional adornments now added consist of large bronze wing castings, 10ft. high, with four tablets in bronze, 5ft. high and 6ft. to 7ft. wide, on a background of granite, one on each side of the relic.

A new Roman Catholic chapel is about to be commenced at the Smyllum Orphanage, Lanark. The cost will be about £2,000. The designs have been prepared by Messrs. Pugin and Pugin, of Westminster.

STAINED GLASS.

SALISBURY.—A handsome memorial stained-glass window has just been placed on the eastern wall of St. Edmund's Church, near the organ, by the relatives of the late Mr. Everett, by whom also two of the other windows in the chancel were erected. The subject is "Praise," the details coinciding with some of the clauses in the Te Deum. All the seven windows in the chancel being now filled with stained-glass, it is hoped some benefactors will come forward and continue the same work in the north and south aisles, so that this fine old parish-church may be completed.

BERGHOLT (EAST).—During the week a stained-glass window has been fixed by Messrs. Lavers, Barraud, and Westlake, art glass manufacturers, London, in the north aisle of the church, near the other window, which is dedicated to the Hughes family. The subjects represented are "The Martyrdom of Saint Stephen," "The Conversion of Saint Paul," "Paul and Silas singing hymns in prison," "The Angel appearing to Paul on board the ship when he was wrecked." There are also single figures, representing "Abraham and Sarah," "The Virgin Mary and Joseph," "Baptism," "Jesus taking up Little Children in His arms and blessing them," "The Marriage in Cana of Galilee," "The Lord's Supper," "Christ Ordaining the Twelve Apostles." At the top of the four bays of the window Jesus is represented delivering His apostolical commission to His disciples before the ascension, "Feed my Sheep," &c.

CHIPS.

Owing to the frequent complaints which have been made during the past few months of the polluted state of the River Thames, there is every possibility that an inquiry will shortly be ordered under the powers conferred by the 31st section of the Metropolitan Local Management Act, 1858, as to the causes which affect the purity of the river near the Metropolis, and the best means that shall be adopted to prevent the polluted condition, if such a state should be shown to exist.

The lives of some two hundred persons, assembled for a special service in Christ Church, Carmarthen, one night last week, were imperilled by the fumes of the heating apparatus being fouled by damp, which, coming in contact with the fire (lighted for the first time since last winter) gave out deadly fumes. Several persons feeling ill without realising the cause, left the church, and then fainted, and at last the vicar himself had to leave the building.

On Wednesday, at a meeting of the members of the Royal Scottish Academy, held in Edinburgh, Mr. George Hay, R.S.A., was elected secretary in room of the late Mr. William Brodie, R.S.A. Mr. David Murray, Glasgow, was elected an associate from among 26 candidates, to fill the vacancy recently caused by Mr. W. F. Vallance being elected an Academician.

The Bridlington local board have appointed Mr. Dyer, of Matlock, as surveyor.

At a recent special meeting of the Newbury town council, the town-clerk was authorised to procure a provisional order "for carrying out the sewerage plan by 'Westminster,' and to schedule Greenhorn Mills and Bone Mill as alternative sites for a pumping-station."

The Warminster local board decided last week to carry out a scheme of sewerage at an estimated cost of £5,000.

The Wesleyan chapel at Kendal is about to be rebuilt from plans by Mr. William Ranger, of London.

The Dean and Chapter of Exeter have decided to light the Cathedral with gas, so that evening services may be held in the building.

The foundation-stone of St. Cyprian's mission church was laid on Saturday week in Brockley-road, opposite Deptford cemetery gates. The architect is Mr. G. S. Fenley, of Buckingham Palace-road, Pimlico, and the builder, Mr. C. Wade, of Manor-road, Lewisham; the cost will be about £1,200.

The Marylebone vestry last week ordered the demolition of five houses in Charles-street, Lisson-grove, which had been described as "fever dens." It was stated that these houses were condemned five years ago.

The corner-stones of a Wesleyan chapel and schoolroom were laid last week at West-end, Sowerby-bridge. The building will be 63ft. by 33ft., and will consist of schools and vestry in basement, with chapel above. Mr. Utley, of Halifax, is the architect; the contract for masonry has been taken by Messrs. Sutcliffe and Son, Sowerby-bridge; and that for carpentering by Mr. J. Greenwood, of Soyland. The estimated cost is £1,000.

Our Office Table.

THE Committee of the Brighton School of Science and Art lately determined to offer annually ten free studentships in science, and the same number in art, to scholars of elementary schools of the borough who have passed the Sixth Standard of the Educational Department. The studentships for this year have now been awarded, twenty boys who passed the highest standard in the specific science and art subjects of the new code at the last Government examination having been selected. The boys with their parents and a number of people interested in the advancement of elementary education, attended a meeting at the school last week to hear an explanation of the objects and conditions of the free studentships. They are tenable for either two or three years, at the option of the holders, the main conditions on which they are held being the regular attendance of the students at the various classes.

The effects of turpentine on some three hundred painters having been studied by a French physician, he now publishes his conclusions, namely, that these effects can never be so severe as to cause death, unless they be volatilised in an extremely confined space,—also, that where there are free movement and good ventilation, no liability to fatal accident exists. The vapours of turpentine coming from different sources, it appears, have not all the same energy; that of the French product, for instance, being far less injurious than the Hungarian or American. The most general form of indisposition exhibited—usually among new workmen, and directly attributable to the turpentine—are headache, watering of the eyes, cough, granulations on the larynx, and disordered digestion.

PROVISIONAL protection has been granted to Edward Haskell, gas engineer, of 280, Oxford-street; and John Pitt Bayley, architect, 18, Fulham-place, Paddington, for the invention of an "Improved Apparatus or Appliance for Heating by Gas." The invention consists of a contrivance to be fitted to ordinary coal-grates, stoves, or ranges, for heating rooms by gas, without smoke or smell, and still appear like an ordinary coal-fire. The object of the invention is to heat by means of gas arranged in a form to be fitted into the present register stoves of any shape, and consist of a metal case, perforated at the bottom, and fitted with rough rock-shaped piece or pieces of glass, to resemble live coal, between the bars of two or more tiers, one above another, and fixed to the outer case by means of catches, flanges, or rivets, and heated by means of jets or burners of gas, the outer case being fitted with a cover dropped into a socket or flange to hold the heat, the foul air escaping through three or more tubes at the back of the lid or cover into a condenser of water, the reservoir of which is constructed at the back of the bottom of the outer case.

PROF. BEILSTEIN, according to the *Pharm. Centralh. from Deutsche Viertelj.*, has made comparative experiments with disinfectants, to determine their relative value as such. He arrives at the conclusion that aluminum sulphate is an effective and at the same time the cheapest substance arresting putrefaction. If sufficient time is given for its action (two to three days) a four per cent. solution will effect more than a fifteen per cent. solution of ferrous sulphate, thereby counterbalancing any difference in price in favour of the later. Besides, a very crude article might be manufactured from clay and sulphuric acid, which would be very cheap indeed. A four per cent. solution of aluminum sulphate will kill all infusorial life, no matter how tenacious. However, this substance has no power of destroying putrid odours, and for this carbolic acid seems to be the only available article. The author inclines to the belief that this disinfectant does not merely supplant foul odours by its own, but that the phenol enters into actual combination with the skatol of the faecal effluvia. He, therefore, recommends aluminum sulphate, combined with a little phenol, as the most effectual as well as economical for rendering decaying organic substances, both odourless and innocuous.

The danger to which the following refers is so little suspected, and yet, as is here proved, so possible, that we think it deserves publicity:—On the 2nd inst., as Vice-Chancellor Bristowe

and Mr. Beckett (editor of the provincial builders' price book) were surveying an untenanted mansion in the neighbourhood of Crewes, an accident occurred, from the above cause, which might have had more serious results. The circumstances were these:—Under the flagged floor of the entrance-hall was an old pump-well which, previous to large extensions made 40 years ago, was, doubtless, outside the house. This well had been covered with oak timbers, which formed the only support to the floor above it; and, up to the time of the accident, did not show the slightest evidence of being less safe than the rest of the floor. The Vice-Chancellor was walking over it when the whole covering suddenly gave way under him and he fell to the bottom. Fortunately, his honour, in falling, got slight foothold on a cross bearer some distance down the well. This, with Mr. Beckett's assistance from above, enabled him to sustain himself until further help could be obtained, when he was extricated from his dangerous position. The Vice-Chancellor—although threatened with the double danger of falling a considerable depth, as well as from the displaced flags which overhung him—maintained great presence of mind, and, we are glad to hear, escaped with only a few slight bruises.

At a meeting of the Birmingham Town Council on Wednesday, Alderman R. Chamberlain, the retiring mayor, announced several munificent gifts to the town in connection with the proposed museum and art gallery. From Mr. J. Chamberlain, M.P., came the offer of two choice paintings by Muller—"Prayers in the Desert," and "A Street in Cairo." Mr. G. J. Johnson and Mr. M. J. Smith offered two valuable water-colour drawings by David Cox, purchased from the estate of Sir Josiah Mason; the mayor himself gave the choice of any two pictures in his collection, and Mr. H. Buckley offered another drawing by David Cox. Following these announcements was an offer of £10,000 for the provision of a new School of Art, on condition that the institution should be under the control of the council; and then the gift by Mr. Cregoe Colmore of a site in Edmund-street, containing 1,000 square yards, and having three frontages, for the proposed school. Lastly, £10,000 more was offered per Messrs. T. Martineau and G. S. Mathews, from an anonymous donor, towards the cost of providing and equipping the school.

A house fell on Wednesday in Fifth Avenue, New York, and buried all its occupants, some 18 in number, beneath the ruins. Considering the rickety look of some of the corner houses in the principal streets in London, it is surprising that we have not more catastrophes of a similar kind in this country. Many of our new houses now in course of erection, on account of the demand for shop-window space, appear to be worse than those they are displacing, and many of the old ones, as we pointed out some time since, in consequence of the removal or alteration of adjoining structures which have hitherto acted as props, are every day endangering the lives of their inmates and passers-by.

Efforts are being made to secure additional railway communication with Southampton. The inhabitants of Southampton have agreed to subscribe £50,000 towards the cost, and the burgesses have sanctioned the investment of a further sum of £50,000 in the undertaking. At the annual meeting of the Newbury Corporation yesterday it was resolved to request the directors of the Didcot, Newbury, and Southampton Railway Company to insert in their proposed Bill for extending the Railway to Winchester and Southampton powers to enable the Newbury Corporation to subscribe £10,000 towards the necessary capital. The new line will establish direct railway communication between the great manufacturing counties of the north and the port of Southampton, besides providing an independent route between Southampton and London.

The Fine Art Society opened on Monday an exhibition of the works of Samuel Palmer, who belonged for a long while to the Society of Painters in Water Colours, and who died only a few months ago. Palmer's works belong to an old school of landscape-painting in which fidelity of detail was little considered, but much attention was paid to grace of form, and balance of composition. More than one drawing in the Fine Art Society's Gallery displays

the studied grace of his rendering of sylvan scenes, and the ordered pomp of his evening skies. The later drawings—such as those which were shown at the Rooms of his own Water-colour Society, last season—do not show any change of method, if they show likewise no decline. In some respects the etchings are as interesting as the coloured works, and although the exhibition, either as regards its coloured designs or its designs in black and white, is not of a kind to attract very general attention, connoisseurs perhaps, without giving one picture higher rank than another, will like to examine the characteristics of the old-fashioned and studiously poetical work.

It is said that the London Gas Company is about to be amalgamated with the great Gas-light and Coke Company, and one of the reasons given is that if the amalgamation be not carried out the smaller company will be forced to undersell the larger. The London Company now charges 3s. per 1,000ft. for gas, and is prohibited from distributing greater dividends than 10 per cent. Any excess must, according to Act of Parliament, be given to the consumers in the shape of reduction of price. It is said that the Company is now literally bursting with wealth, and that if not "amalgamated" it will be forced to reduce the price of its supply. To avert this terrible evil another great transaction in London gas is likely to take place, with the consequence that whenever the municipality takes over the gas manufacture a still heavier burden will be imposed upon the ratepayers of the metropolis.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Surveyors' Institution. Opening address by the President, E. Hyde. 8 p.m.

TUESDAY.—Institution of Civil Engineers. Discussion on C. Wood's paper, "Iron Permanent Way." 8 p.m.

WEDNESDAY.—Society of Arts. Address by Sir F. J. Bramwell, Chairman of Council. 8 p.m. British Archaeological Association. Opening Meeting. "The Borg ez Zifih, Cairo." By Prof. T. Hayter Lewis, F.S.A. "The Measurements of Ptolemy in Relation to the Western Portion of Britain." By Gordon M. Mills. 8 p.m.

Edinburgh Architectural Association. "The Building Stones of Scotland." By Connciller Gowans. 8.30 p.m.

Throat Irritation.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycérine Jujubes. Glycérine, in these agreeable confections, being in proximity to the glands at the moment they are excited by the act of sucking, becomes actively healing. Sold only in boxes, 74d. and 1s. 11d., labelled "JAMES EPPS and Co., Homoeopathic Chemists, London." A letter received:—"Gentlemen.—It may, perhaps, interest you to know that, after an extended trial, I have found your Glycérine Jujubes of considerable benefit (with or without medical treatment, in almost all forms of throat disease. They soften and clear the voice.—Yours faithfully, GEORGE HOLMES, L.R.C.P.E., Senior Physician to the Municipal Throat and Ear Infirmary."

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, RHEUMATISM, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute. See Medical Testimony.

Holloway's Ointment and Pills afford comfort, security, and oftentimes recovery to the most tortured sufferers. The Ointment, when properly used, will cure all description of sore, wounds, eczema, sprains, erysipelas, rheumatism, gout, and skin diseases. The Pills are infallible in biliary and digestive derangements, sick headache, and constipation.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to **CHARLES TRASK,**

Norton-sub-Hamdon, Ilminster, Somerset.
—[ADVT.]—

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates.

General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country.—[ADVT.]—

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE.
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.

(See trade advt. on p. XXIII.)

ADVT.

TENDERS.

* * * Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ABERGAVENNY.—For construction of an iron footbridge over River Usk, at Abergavenny. Messrs. Dudley and de Salis, engineers, 1, Westminster-chambers, S.W. :—

Horton and Son, Darlaston	£547	0	0
Verdon and Ewens, Cheltenham	525	15	0
Dyne, Steel, and Co., Newport	405	0	0
Brettell, J. C. and C.E., Worcester*	360	0	0

* Accepted.

BANSTEAD, SUSSEX.—For engineering works in connection with the laundry and bath-house, &c., at the Kensington and Chelsea District School, Bantead, for the Managers, Messrs. A. and C. Harston, 15, Leadenhall-street, architects :—

Benham	£1,655	0	0
Clements	1,250	0	0
May	1,080	0	0
Bradford and Co., High Holborn*	991	10	0

* Accepted.

BATTERSEA, S.W.—For the enlargement of a school in course of erection in Raywood-street, Fatersea Park-road, from 1,200 to 1,400 school places, for the London School Board. Mr. E. H. Robson, F.S.A., architect to the board :—

Downs, W., Walworth (accepted on a schedule of prices).

BEDFORD.—For a detached villa residence in the Oval, Ashburnham Estate, Bedford, for Messrs. Hawkins and Ashwell, The Oval, Bedford. Mr. H. H. Bridgman, A.R.I.B.A., 42, Poultry, E.C., architect :—

Spencer, T., Bedford (accepted) £1,211 0 0

BEOPORD.—For six detached villa residences in the Lansdowne-road, Ashburnham Estate, Bedford, for Messrs. Hawkins and Ashwell, The Oval, Bedford. Mr. H. H. Bridgman, A.R.I.B.A., 42, Poultry, E.C., architect. Quantities by Mr. F. Thomson, 20, York Buildings, Adelphi, W.C.

Spencer, T. (accepted) ... £6,683 5 0

BELPER.—For the erection of a chimney at the workhouse, for the Belper board of guardians :—

Hingley, of Duffield (accepted) ... £50 0 0

[Highest tender received, Marshall, £130 5s. 8d.]

BRAWLEY-ON-TWEED.—For repairing several breaches in the ramparts :—

Messrs. M. Gray and Son (accepted).

BARWICK-ON-TWEED.—For repairing a part of Hide Hull :—

Brough, J. (accepted) ... £78 13 9

BETHNAL GREEN, E.—For laying 700ft. of 18in. pipe sewer in Hollybush-gardens, for St. Matthew's vestry, Bethnal Green. Mr. W. H. Gathercole, surveyor :—

Barnes, Bethnal Green	£541	0	0
Wilkes and Co., Bishopsgate	511	0	0
Finch, Mile End	457	0	0
Wood, F., and F. J., Mile End	418	0	0
Porter, Hackney	394	0	0
Nobbs, Mile End	368	0	0
Killingbeck, Camden Town	367	0	0
Judd, Mile End	352	0	0
Reeves, Bow	345	0	0
Armstrong, Chiswick	336	0	0

(Surveyor's estimate, £390).

BIRMINGHAM.—For the erection and completion of schools in Icknield-street, and a chemical laboratory, for the School Board :—

Horsley Bros. (accepted) ... £9,618 0 0

BRIDGEND, GLAM.—For alterations to the workhouse, for the Bridgend board of guardians :—

Morgan, J. (accepted) ... £51 0 0

BROMLEY-BY-BOW.—For the erection of a mission house at St. Leonard's road, Bromley, Middlesex, for Miss Emily Currie. Messrs. A. and C. Harston, 15, Leadenhall-street, E.C., architects. Quantities supplied :—

Smith	£800	0	0
Atherton and Latta	745	0	0
Walker	738	0	0
Holland	723	0	0
Carpenter and Poole, Pentonville*	697	0	0

* Rednead to, and accepted at, £653.

BRONDESBURY, N.W.—For construction of waggon-shed and storehouses, Dym-road, Brondesbury, for the Willesden Local Board. Mr. O. C. Robson, surveyor :—

Lifford	£646	0	0
Coulter	635	0	0
Baxter	544	0	0
Haynes	440	0	0
Crockett	440	0	0
Neave and Son (accepted)	430	0	0

CARLISLE.—For the completion of Carlisle Grammar School, for the governors :—

Accepted tenders.

Plumbing :—

Alderson, Carlisle and Glasgow ... £679 0 0

Slatting :—

Nau-on, Carlisle ... 485 0 0

Trework :—

Stunfield, D. W. and Son, Carlisle ... 42 10 0

Plastering :—

Ormerod, D. M., Carlisle ... 397 0 0

£2,043 10 0

[Amount of contracts for masonry, carpentering, &c., previously let, £7,337.]

CHESTER.—For sanitary work at the workhouse, for the Chertsey board of guardians :—

Hunt, R. J. ... £75 0 0

Brown Brothers ... 65 0 0

Forsey, J. ... 64 10 0

Nesmyth, H. J. (accepted) ... 54 18 0

CHEATERS.—For the erection of a stone breacher's shed at the workhouse :—

Forsey, J. (accepted) ... £34 10 0

CHESHAM, Bucks.—For laying 7,300 yards of stoneware pipe sewers, 15in. to 9in. diameter, and 600 yards of 15in. ditto, subsoil drainage works, and sewage disposal works, for the Amersham rural sanitary authority, being Chesham sewerage contract No. 1. Mr. James Mansergh, 3, Westminster-chambers, S.W., engineer:—

White, G., Shepherd's Bush ...	£10,861 13 5
McKenzie, Williams, and Co., ...	9,500 0 0
Moorgate, E.C. ...	9,457 4 0
Kellett and Bentley, Mansion House Buildings, E.C. ...	9,472 8 4
Smith, J. M., 1, Westminster-chambers, S.W. ...	9,421 4 7
Dickinson, J., Beckenham ...	9,371 13 6
Kyan, A., Lanchester ...	8,850 8 2
Bottoms Bros., Lavender-hill ...	8,877 16 7
Neave, J. W., Lewisham ...	8,632 13 10

Walters and Johns	1,040 0 0
Evans, D.	990 0 0
Morgan, D., Swansea (accepted)	950 0 0
Reed, T.	900 0 0

SWANSEA.—For the erection of a truant school at Bony-maen, for the Swansea School Board. Mr. Humphries, architect:—

Rees, D., Ystadyfryn	£3,163 0 0
Morgan, D., Swansea	3,100 0 0
Thomas, Watkins and Jenkins, Swansea*	2,800 0 0
White, E.	2,800 0 0
Walters and Johns	2,775 0 0
Rees, T., Swansea	2,659 0 0

* Recommended for acceptance.

THE MIDDLE LEVEL FENS.—For the strengthening of portions of the Barrier bank of the Old Bedford River, for the Middle Level Commissioners:—

White and Broadhurst (accepted)	£3,975 0 0
--	------------

TIPTON (STAFFS).—For making, kerbing, channelling, &c., Ball Fields and Boscobel-street, in Tipton, for the local board. Mr. William Turnbull, surveyor:—

For Ball Fields Boscobel-street.	
Shortland, J., Bilston*	£253 2 0
Tranter, T., Tipton Green	240 0 0
Currell & Lewis, Birmingham	248 15 0
Smith, C., Smethwick	242 10 0
Howl and Co., Tipton	242 17 5
Cashmere and Bullas, Horsley Heath, Tipton*	198 9 0
Surveyor's estimate	213 15 8
* Accepted for Ball Fields. + Accepted for Boscobel-street.	

TIPTON.—For building a new house in Boscobel-street, for Mr. T. G. Hicks:—

Clemens and Tippet (accepted)	£1,000 0 0
--------------------------------------	------------

WANDSWORTH, S.W.—For the enlargement of school in course of erection in Fountain-street, Wandsworth, from 1,200 to 1,409 school places, for the London School Board. Mr. E. R. Robson, F.S.A., architect to the board:—

Jernard, S. J., Lonspit-vale, Lewisham (accepted on a schedule of prices)	
--	--

WANDSWORTH, S.W.—For alterations and additions to Durham House, Southfields, Wandsworth, for Mr. F. Stroud. Messrs. Humphris and Co., Cheltenham, architects:—

Adamson and Sons	£790 0 0
-------------------------	----------

Scott, H.	776 15 0
------------------	----------

Turtle and Appleton	650 0 0
----------------------------	---------

Foote, J.	610 0 0
------------------	---------

Sutton, J. (accepted)	560 0 0
------------------------------	---------

WHITCHURCH, SALOP.—For supply of cast-iron pipes, sluice valves, connections, hydrants, &c., for new water-works of the Whitchurch and Doddington local board. Mr. W. Wyatt, engineer, Ellesmere, Salop:—

R. P. Smith and Co., Whitchurch, Salop (accepted), for cast-iron piping only, per ton:—7in. £4 10s. 6d., 6in. £4 11s. 6d., 5in. £4 12s. 6d., 4in. £4 13s. 9d., 3in. £4 13s. 9d., 2in. £4 17s. 6d.	
---	--

WIDNES, LANC.—For widening Adam's bridge for the town council:—

Holme and King, Wigan	£535 0 0
------------------------------	----------

Ashcroft, W.	533 0 0
---------------------	---------

Whitehead, Son, and Berry	497 0 0
----------------------------------	---------

Winnard, W.	485 0 0
--------------------	---------

Preston, J., Wigan (accepted)	425 0 0
--------------------------------------	---------

Walmsley, M. W.	317 0 0

TURPIN,
22, QUEEN'S ROAD
BAYSWATER, LONDON, W

MANUFACTURER OF

The Best and Cheapest

PARQUET FLOORINGS.

150,000 ft. super. in Stock, ready for Laying
RIGA INCH OAK FLOOR BOARDS,
1s. per foot super. (grooved & tongued).
Immense Stock always ready for Laying.

ARTISTIC JOINERY

THIN PARQUET

Turpin's Patent. 5-16 inch thick, prepared on deal back laminations, equal in wear to inch Solid Parquet. Used for Veneering and existing deal floors, and is susceptible of removal at pleasure. See Construction.

ORNAMENTAL

PARQUET.

DEAL

BACKING.

WOOD CARVINGS.

All Styles executed for the Trade at Special Rates. Skilled Artisans sent to all parts of the country.
Estimates and Designs on Application.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 18, 1881.

ARCHITECTS AND THE PUBLIC.

THE new President of the Institute at any rate manages to get the ear of the public—quite a new thing of late years, as far as Presidential utterances at Conduit-street have been concerned; and if Mr. Street's outside hearers do not all agree with him, they evidently appreciate the difference between the standpoint from which he addresses the profession and the public, and the narrower one which has contented his more recent predecessors. For the most part, however, the comments on Mr. Street's address which we have seen have not seemed to us characterised by any very intimate acquaintance with the subject or a disposition to do much else than grumble. The most noteworthy are, perhaps, contained in an article in the *Spectator*, which we reproduce elsewhere, and in a letter in Monday's *Times*, signed "Means and Ends," the writer of which thinks "that most people would gladly avail themselves of the services of an architect if he could inform them with certainty as to the cost of building a house." He then informs us that he built a house, the extras upon which amounted to 25 per cent. and the architect's charges to 7½ per cent. An architect's estimate was afterwards obtained for altering a house, but the correspondent thought the amount excessive, and ultimately he carried out an identical alteration on another house, without an architect, the builder's bill, with 3 per cent for extras, amounting to "just one quarter of the architect's estimate." Now, without giving undue credit to unsupported statements of this kind, we think the letter does to some extent represent the experience of many people in their relations with the profession. The mind of the public has become prejudiced against architects and their charges, and we are inclined to think, as we hinted last week, that this is one of the most likely reasons why the services of the profession are not more sought. Take the cost of building a house. A good and ingenious plan, one of the first necessities in building a convenient and comfortable house, is a thing that hardly need to be paid for. Any person who contemplates building has probably an arrangement in his mind's eye which will give him what he wants. It is comparatively easy to get a respectable builder to carry out any plan that may be suggested to him at the cost of labour, materials, and a fair profit. The ordinary resident who builds his own house is well satisfied if his requirements are met at a price which is reasonable. He seeks only convenience in the appointments of a well-equipped house, and if he can get these at an expenditure which bears a fair proportion to the cost of renting a house of the same size, he is well pleased. About the artistic qualities of the house he has little or no concern. If he employs an architect he gets a design in an expensive Italian, Queen Anne, or Gothic style fitted to a plan which has been the result of secondary considerations, at an extra cost of from 10 to 20 per cent. The question is whether the services of the architect are really well paid for at that price, whether the owner gets the kind of house he wants, and whether the money spent on artistic design has been laid out to the best advantage. The builder does not charge for the design—only a certain percentage on materials and labour, when he is employed without supervision.

When an architect is engaged his percentage is generally doubled by the requirements of bills of quantities and measurement and valuation of extras. It is customary also for contractors to add a percentage when they have to work to plans and a specification under an architect's supervision; and all these extra charges fall upon the client. The system of payment by percentage has unfortunately increased the aversion with which some people regard the architect. He is looked upon as an intermediary, a middle man whose service can only be to add to the cost. It is very excusably thought that the architect's interest is to increase the cost of the building by means which are not absolutely necessary to its proper completion. The practical Englishman is the last person to pay for what he may call imaginary perfections and æsthetic refinements in house-building, and unfortunately architects are not always scrupulous or careful enough to insist on the more substantial qualities being incorporated.

It is—we may as well frankly acknowledge it—a hard thing to obtain a reliable estimate from some architects; their estimates are too frequently deceptive. Can we wonder? Less than half a century ago the estimate of a building was considered one of the first duties of the architect. Careful measurement and valuations were made, and the client knew beforehand the approximate cost of his building. Now these matters are left too frequently to the surveyor, and are counted beneath the notice of the architect. Mr. Street, in drawing so favourable a picture of the state of vernacular architecture a century ago seems to have overlooked this essential change in professional practice, and to have failed to take into consideration another element which has tended to injure good building of the class he referred to. We allude, of course, to the contract system which has taken the place of the measure-and-value method. That change has made good workmen scarce, and has created a class of men little experienced in any one branch of building, but who have just business capacity enough to employ workmen of inferior skill, and to tender for work on the lump sum. The effect of competition, both amongst builders and architects, has been equally detrimental to honest workmanship and solid building. The sham fronts and false use of materials so prevalent, of which the President spoke, have naturally arisen from the desire to excel in the outward qualities of building which the competition system has promoted. The requirements, too, of this system of obtaining designs have necessitated the preparation of show-drawings, and hence a class of draughtsmen have sprung into existence who have vied with one another in the pictorial representation of architecture and elaborate ornamentation, and in nothing else.

It is a side question—but it is one, after all, not distinctly related to the dishonesty of vernacular architecture—to what degree the modern draughtsmanship of which the President spoke in such high terms is answerable for the loss of solidity and the display of extravagant ornament in the buildings of the present day. There is also another potent cause for the existence of flimsy buildings to be found in the system of leasehold tenure which exists in this country. What inducement is there to build solidly and honestly on sites which in a few years will fall into the hands of the freeholder? The old builders reared their solid and artistic buildings in anticipation of the natural term of their existence: they spared no expense in thick walls and substantial floorings and roofs, for the risk of forfeiting the property at the expiration of a few years was not contemplated. No influence has so powerfully operated to check good architecture than the parcelling out of small plots

on short leases, and this is a circumstance over which the architect has no control. The term restricts the expenditure, the class of house to be built, and its general character, and the builder who knows how to meet the tastes of the public resorts to the show front, with its tawdry ornament of stone or composition, as the only solution of the difficulty. It is, however, the duty of the architect to set the example of solid construction and good planning, even under these circumstances, and it is necessary to enforce the sound dictum of the President, that the highest art can be shown in such a practical matter as the best disposition of a ground-plan. If the public hold aloof from the employment of architects in ordinary buildings, it is not always, it must be remembered, because they ignore art, but because the architect ignores the practical elements of cost and construction, and has, by his own action, made it possible that a building can be erected without art, and at less cost.

CITY IMPROVEMENTS.

AMONG the many alterations which have been made in the City of late years, that portion of it bounded on the west by Farringdon-street and on the east by Aldersgate-street, and comprising West Smithfield, has probably seen most of demolition and reconstruction. When Holborn Viaduct was formed, a large and densely-covered area of dwellings had to be removed, and there was a hope expressed that the cleared space might be turned to the best account architecturally. Seldom has one scheme of reconstruction given the opportunity for so complete a remodelling. Much as we owe to that important alteration in having at least been the means of making two or three handsome thoroughfares, and in sweeping away blocks of insanitary dwellings, it cannot be denied that a much more perfect and thorough scheme was possible in the area dealt with by the Viaduct. There was a splendid opportunity for civic architectural display in the Valley improvement. The three diverging thoroughfares to the east of Holborn-circus—namely, Charterhouse-street, Holborn Viaduct, and New-street, opened up some capital sites, if conflicting interests had not entered. The last-named street is a poor and crooked thoroughfare which might have been planned with more skill; Farringdon market has long been an eyesore, and the awkward cutting or incline made by the London, Chatham, and Dover Railway from Ludgate-hill station on the east side of Farringdon-street, has spoilt the area of building ground on that side.

We here speak of the area on the south side of Charterhouse-street, adjoining the Metropolitan Meat and Poultry Markets at Smithfield and Snow-hill. This site has for a long time been a desolate waste of ground cut through by the Chatham and Dover line, and perhaps we could instance no other locality where the conflict of railway and civic authorities has played such havoc with property. No plan is evident, and the space seems to have been left to chance. Lately, the Corporation have covered a large part of this waste by the new Central Fruit and Vegetable—or Fish—Market, for it is as yet a matter of some uncertainty which it is to be. The buildings have extensive frontages towards Charterhouse-street and Farringdon-street, and these are three-story erections of red brick with stone dressings, the ground-story being occupied by small shops. The elevations are in a neat Renaissance style, with stone pilasters carrying a cornice in the upper story, and with a high curb roof broken by dormers of stone. The main points of relief are the three chief entrances on the north, south, and east. One of these is towards Charterhouse-street, where the sides of the houses

are played and an arched roof is in course of construction. Between this thoroughfare and Farringdon-street the corner is emphasised by an entrance-archway entirely of stone. The frontages are finished at this point by pavilion or octagonal-shaped towers with low pyramidal roofs having rather large and heavy-looking gilt pine-apple finials. The archway between is set back and is carried up as a square tower crowned by a quadrangular cupola. On each of the sides elaborately-carved dormer gables are placed, and panels are introduced over the arch sculptured with the arms of the City, and festoons of fruit and foliage. These are carved with some spirit, as also the swags of fruit and flowers on the upper faces of the flanking octagon turrets. Less satisfactory is the grouping of the shops in Charterhouse-street, which are stepped every two houses to follow the inclination of that street, thus breaking the lines of the entablature and pilasters. The latter more noticeably have a rather awkward appearance, the capitals stopping the cornice lines, and the party walls thereby rather obtrusively showing themselves above the roofs. At the south corner of the block is another entrance to the basement, the main feature of which is an octagon tower of brick, the angles having stone pilasters, and the roof of a steep, spire-like form.

There are about 40 shops fronting the streets, which will be let for retail purposes; these are plainly fitted up, the story-posts being of east-iron, forming pilasters in front, and carrying plate girders or breastsummers which support the fronts. The main area of the market, which is on a level with the Meat-market, and covers about 44,060ft. superficial, is roofed in with iron and glass, lattice iron girders and arched ribs, supported on octagon-ribbed columns, with glass louvres along the ridge and springing, being the principal features. These are painted light blue, relieved by red. The span of roof is 45ft., and a central octagon turret marks the centre. The height to the ridge is also about 45ft. The central market area will consist of shops with pitching stands for goods and waggons, and will be approached by the entrances we have described, and two others for foot-passengers, and is only interrupted by the rows of columns supporting the roof. A roadway from Farringdon-road gives access to the basement, which will be used for railway and waggon traffic. Of course it has been necessary to cover over a portion of the Chatham and Dover line, which intersects the site and passes under New-street.

Taking note of other improvements in this locality, we see the corner of the last-named street and Holborn Viaduct, a very eligible site, has been filled up. The corner was long an unsightly plot, and the new building is a block of shops and offices facing the L. C. & D. R. Hotel on Holborn Viaduct. Stone, white facing bricks, and compo not long ago ruled supreme in this part of Holborn; the new shops are of red brick, with a mask of stone pilasters in one order, and a pediment in the rounded corner, always a very undesirable and inartistic feature in such a situation. On the architectural design of this large addition to the business architecture we cannot bestow much praise. The stone pilasters look heavy and squat; their carved capitals are massive and overpowering. A rather heavily-designed stone arched entrance is one of the main features of the front, and the shops have mezzanines, the latter being designed in a Gothic manner entirely out of accord with the superstructure. The celebrated Cock-lane, noted for the ghost-story of that name, still retains a few of its old houses, though the infection of improvement has spread, as we see by an attempt at Venetian Gothic in one front of new premises, and in other instances. A proposed new street was con-

templated from St. Sepulchre's Church, through Christ's Hospital eastwards, but it is still in abeyance.

In Warwick-lane many ancient houses of the 17th century are to be seen. We notice the new deanery-house of St. Paul's, a building of red brick in the Queen Anne style. The building is set back from the street, a wall and iron gates enclosing a forecourt. The principal point of interest in the new building is an arched gateway with wrought iron gates in the centre and wings; the gables are panelled, filled in with herring-bone brickwork. In Warwick-square one large building or warehouse is being constructed, but of no architectural merit. Among the old buildings which have been demolished is the fine old brick group of the College of Physicians, designed by Wren, and half-way down the lane stood the "Oxford Arms," a curious old hostelry. A warehouse in Newgate-street is worth notice for the manner the front is treated. The lower shops are divided by Ionic pilasters in stone, which rise to the height of an entresol. These are carried up through a light red brick superstructure mainly consisting of brick pilasters between the windows and horizontal lines of walling. The arches have their tympana carved in red brickwork, and the upper story is marked by a centre gable with dormers at the sides. At the back of Ludgate-station another large warehouse has been erected of red brick and stone in a fashionable style. The block is called the Gresham Press Buildings. The ground-story and mezzanine have green painted wood framing between stone pilasters; the superstructure is chiefly of red brick relieved by a stone oriel and archway at the corner; but the treatment and details of the stonework are rather coarse. In Farringdon-street, near the Viaduct, two large blocks of warehouses have been constructed; the materials are red brick and stone, and the manner these have been introduced call for approval. They are at least partially successful attempts to impart to warehouse fronts a lighter and less gloomy effect than that of old work of this sort, without encroaching on the domestic or palatial types of design. The windows are wide and open, with sills, lintels, and pilasters of stone, in lieu of brick-arched openings in a solid brick wall, which in their exceeding severity made the fronts look almost prison-like.

THE LONDON SCHOOL-BOARD DRAWINGS.

THE annual exhibition of drawings by scholars and pupil-teachers, sent up by the various board-schools in the Metropolis, is on view this week at the Saffron-hill school in Farringdon road. We can hardly say the exhibition is quite equal to those of former years, yet the drawings are interesting as showing the progress made by the pupils in these schools. The ages of those who have contributed drawings are generally between 13 and 15 years, so that the visitor cannot expect to find any advanced work on the screens. The schools in the Chelsea division, which we may take first, exhibit some creditable work by juniors. We may point with satisfaction to the contributions from the Portobello-road school generally, by pupils from 13 to 14 years old. The drawings are chiefly freehand ornament from the flat. Some of the outlines indicate precision, and a grasp of form which would do credit to pupils of advanced years. The honeysuckle and folial ornaments are in some instances very praiseworthy specimens. We can also speak in favourable terms of the work done in the William-street school, especially that of the girls, in which the ornament shown has much precision of character. The

Saunders-road school sends two good perspective drawings, one of a hexagonal pyramid in perspective, by J. Crossley, age 16. Freehand ornament, evincing careful teaching, comes from Latimer-road, Queen's Gardens, Harwood-road, and Marlboro'-road schools. It would much assist examination and comparison if the several specimens forwarded by one school were arranged in a series and mounted, in the manner in which those from the Marlboro'-road school are done. The pupils' names are neatly written in red under each drawing, and these are executed on the same toned paper and mounted. A very miscellaneous assortment of studies comes from Victoria-road school, and we see a few comic ink copies from prints, made by a pupil of the Clifton-road school. It is very questionable whether such copies are judiciously allowed in schools; we certainly think they are not strictly artistic drawing, however clever they may be. Such a drawing as that in pencil by a pupil of Glengull-road school, Tower Hamlets, representing "Long Branch, New Jersey, the House where President Garfield died," is a praiseworthy attempt to unite art with incident, though the effort is manifestly out of proportion with the capabilities of the youthful aspirant. The same may be said of an "Italian Landscape" close to it. Brunswick school, in the same district, sends some clever outline drawings by girls. Greenwich is not distinguished this time for its art-work. The copies in chalk of heads sent by the Edward-street school, and the tawdrily-coloured illuminated text by a pupil of Powis-street school, "God our Home," are instances of art training which ought not to be encouraged in our schools. It is teaching the pupil to run before he can walk. Drawings of a pictorial kind are ill-suited to train or to promote a pupil's accuracy of hand or eye; pictures are apt to wean the attention from those essential points of good perspective and drawing which are so absolutely necessary. We find, however, several drawings of this class hung. Fleet-road school, Marylebone, and several of the Lambeth board-schools, as those of Westmoreland-road, Penrose-street, &c., have specimens in which pictures and prints have furnished the copies. Hackney is well represented in the exhibition, and the work of the schools of this district is on the whole creditable to the masters. We may mention more particulars the Turin-street school girls' drawings, in which carefully drawn outlines of vases and ornament are the chief objects. The Scrutton-street school free-hand studies are also commendable in both the boys' and girls' departments. The schools at Gainsborough-road, Rendlesham-road, Berger-road, Cadogan-terrace are the contributors of some well-executed pencil perspective and freehand ornament. Rendlesham-road sends a few capital copies of architectural ornament and pottery. Marylebone is also represented well, as in the work of Medburn-street school, Aldenham-street, Bath-street schools.

Finsbury takes the place of honour for the neat and uniform way in which the Poole Park school drawings are mounted and hung. These have been selected and are arranged in an artistic manner on large mounts. The freehand ornament and flower drawing are highly commendable to the managers of this school of both departments. In one of the large mounts, a series of studies of Greek and Italian ornament, and others of a geometrical character, have been arranged symmetrically, some of them having been simultaneously drawn from copies on the blackboard. The girls' drawings have been similarly arranged, and the shaded ornament and flowers reflect credit. Canonbury-road school exhibits a few good

drawings, so does Duncombe-road and York-road schools. Seven Dials and Thornhill-road are also among the number. Southwark and Lambeth make a goodly show of drawings; the latter are of a somewhat heterogeneous character and not well selected, though a few schools contribute good specimens. Of the Southwark schools we may mention Keeton's-road as standing well; Rotherhithe-road and Hatfield-street schools are too pictorial, and better work in the elementary standards would be more satisfactory evidence of progress.

SCOTLAND IN EARLY CHRISTIAN TIMES.*

THE second series of the Rhind Lectures on Archaeology, abstracts of which have appeared from time to time in our pages for 1880, has just been published. The author, Mr. Joseph Anderson, keeper of the National Museum of the Antiquaries of Scotland, in the present volume continues the subject of his previous lectures on the remains and relics of Early Christian times, by describing a variety of art-relics of indigenous types found in Celtic Scotland. Mr. Anderson has ably classified these relics, which consist of decorative metalwork, such as gold, silver, and bronze brooches of Celtic design; decorative stonework, comprising various groups of monuments with pictorial and conventional symbols, he also discusses the symbolism of the monuments, and the inscriptions found on undated monuments of the 12th century. Increased interest and value are given to these descriptions by numerous wood-engravings and photographic reproductions which represent every type of the art work of these interesting ages. One of the beautiful relics of artistic workmanship in gold and silver is the Hunterston brooch, found by a shepherd in 1826. It is circular in shape, about 1½ in. diameter, with a pin 5½ in. in length. The brooch consists of a flattened ring of silver half an inch wide, expanded to a crescent shape on one side. The design is symmetrical on each side of the pin. The surface of the ring is divided into panels or sunk spaces, and the corners of the crescent-shaped portion are relieved by amber settings. The panels are farther enriched by filigree interlaced forms, the character of which is zoomorphic, characteristic of Celtic art as we see it in illuminated manuscripts of the Gospels. The edges are also decorated with long panels of simple interlaced patterns, the diverging spiral and trumpet pattern been introduced. The author says, "The elegance of its design is almost equal to that of the best manuscripts," and cannot be surpassed by modern art workmanship, while the ornamentation shows a pure feeling and delicacy not to be found in metalwork of our age. The inscriptions are in the later and more local variety of the Runic alphabet known as the Scandinavian, and refer to ownership. The author proceeds to inquire whether this brooch is Celtic or Scandinavian, and examines a series of brooches decorated with the same art found in various parts of Scotland. All the examples illustrated are of this half-crescent form. The Sutherland brooches have indeed a special form, the ends of the ring of metal expanding into circular compartments, and their decoration consists of very delicate patterns of interlaced work of gilt. One of the most interesting examples of design is a fragment of a silver brooch inlaid with gold found at Dunbeath, Caithness. It is a fine specimen of Celtic work, the most perfect, says Mr. Anderson, that he has ever seen. The decoration shows panels in the crescent part, a fine cable border running round, and the centres and

borders filled with delicate filigree of curvilinear form. Illustrations are also given of the priceless Tara brooch, and others of extreme beauty in form and decoration. The author distinguishes the characteristics of this peculiar type of brooch as penannular, or a ring of metal not continuous, but having an opening between the two ends. The Anglo-Saxon brooches are disc-shaped, the Scandinavian, oval and bowl-shaped. On the other hand, these are essentially Celtic in the style of the Christian time.

We cannot afford room to follow the author in discussing the question of the area of this type of brooch. The Celtic forms are found mixed with those of Scandinavian origin in the same graves, but the presence of Christian Celtic relics in heathen burial-places in Norway is easily explained by the fact that the latter country was heathen for fully four centuries after Christianity had been established in Scotland by the followers of St. Columba, and that the Vikings were continually engaged in plunder across the North Sea.

Lecture II. describes a series of monuments of stone, consisting of finely-sculptured slabs and crosses of Celtic form and ornamentation. Some of these were discovered in an old church, St. Vigean's, in Angus, in which they had been utilised by the 12th-century builders. One slab bears an elaborate cross of interlaced work, the spaces between the cross and raised edging being filled with grotesque figures of non-descript animals. The lacertine creatures with twisted tails found in the metalwork we have mentioned are found here also, showing the art to be of the same age and character. Other fragments of sculptured stone consist of portions of cross-slabs, free-standing crosses, &c., all sculptured with ornament and figure subjects. The example engraved from Aberlemno, Forfarshire, shows a richly-sculptured cross with interlaced ornament, with convoluted and intertwined creatures of dragon-like form in the borders, in all respects like the forms seen in the Celtic MSS. of the Gospel, while on the reverse side is a sunk panel, with a symbol of mysterious import, and figures of men and horses engaged in combat. The slabs found in Perthshire, and illustrated by photographs, are beautiful specimens of Celtic ornamentation, and the plates give excellent representations of these very remarkable sculptures. At Meikle, another group was found of a similar or Transitional character, which are described in detail, and the peculiar features of these slabs are a cross on one side, with figures and symbols on the reverse, the ornament being interlaced work, spirals, and fretwork. Oblong, boulder-like stones, with symbols of simple incised lines, instead of relief sculptures, are associated with these shaped slabs, and the author discusses the area they occupy, which is the same as the decorated type. The inscribed and decorated slabs have been assigned to the period between the 7th and 12th centuries. The first limit is thought conjectural. The author thinks the higher phase of monuments carved in relief was probably developed in Ireland at an earlier date than in Scotland, and he, therefore, assigns the decorated monuments of Scotland to a later date than the commencement of the 10th century, and the incised monuments to a period immediately preceding. In another lecture, the art characteristics of these monuments are discussed at greater length, and the author compares the peculiar features, and endeavours to determine their relations to the Early Celtic art found in metalwork and manuscripts. The plates and engravings exhibit many beauties of interlaced work, fretwork, and other kinds of surface ornament, and these are analysed. Endless modifications of the rectilinear fret appear, which show affi-

nities with Greek and Oriental patterns. "No nation," says Mr. Anderson, "ever developed the capacities of the rectilinear form of ornament in the special manner we find in Celtic manuscripts and monuments." Space forbids our entering into the subject of the symbolism of the monuments, discussed in the fourth lecture. The symbolism of the Scottish monuments is possessed of a double character: it is of independent origin, but there are representations which are also variants of universal types, disguised and degraded in their passage from the higher art of the Primitive Church to the later local art of the Celtic Church, which was always weak in pictorial representations. These consist mainly of Scriptural subjects, intermingled with grotesque and fabulous and allegorical forms.

Ogham inscribed stones are also included, and the author has generally presented the various relics and types in a scientific order, which cannot fail to lend to the study of Early Scottish archaeology an interest it undoubtedly possesses when rightly understood.

THE WATER QUESTION.—XXI.

PRESSURE.

THE force and mode of action of water under pressure along and at the end of a main pipe may be worth considering in connection with its storage in reservoirs such as have been described. The pressure of still water is the weight of a vertical column of it above the place where the pressure is measured; but still water does no work, and when the column is in motion the pressure is less. The weight of water is as follows, the foundation being the Troy grain, 5,760 of which used to make a pound weight; but this pound not being satisfactory for general purposes in England, the pound weight was increased to 7,000 of those grains. An Act of Parliament made a gallon of distilled water at the temperature 62° F. to weigh 10lb., or 70,000 grains, in air of the density produced by a pressure equal to the weight of a column of mercury 30in. high; and established also, from experiments which had been made by a commission, that a cubic inch of distilled water at the temperature and pressure above mentioned weighs 252.458 grains. A cubic foot therefore weighs $252.458 \times 1,728 = 346,247$ grains, or $\frac{346,247}{7,000} = 62.321$ lb. In half a dozen different tables of the weight of mercury, compared with that of water, six different values may be seen—viz., 13.56, 13.568, 13.57, 13.58, 13.596, and 13.6. When tables differ, what is the proper weight? The difference seems to arise from comparing the weight of mercury at one temperature with that of water at another, in some cases, and in other cases in taking water sometimes at the temperature 39.2° F., when it is at its greatest density, and at other times taking it at the common temperature of 62° F. This latter is the more useful for ordinary purposes. At 62° F. mercury is 13.596 times heavier than water. The pressure of the atmosphere then is the same as a column of water $\frac{30 \times 13.596}{12} = 33.99$ ft. high, or 34ft., and the corresponding pressure per square inch is $\frac{34 \times 12 \times 252.458}{7,000} = 14.71$ lb. When the mercury rises to 30.5in. the pressure is 15lb. nearly per square inch. But as the weight of the atmosphere is often less than 30in. of mercury, and sometimes only 28.5in., it is the minimum pressure which should be reckoned upon in practice in order to guard against failure of action at all times. This is $\frac{28.5 \times 13.596}{12} = 32.29$ ft. of water, and the corresponding pressure per square inch is

* Scotland in Early Christian Times. (Second Series.) By JOSEPH ANDERSON. Edinburgh: David Douglass.

13.97lb. or 14lb. As the head of the column of water is open to the atmosphere equally with the point at which the pressure is applied, this pressure is "above the atmosphere," and although there may be a little difference between the pressures of the atmosphere at the two ends of the column, measured at the same instant, if the pressure reckoned upon be that of the minimum there will be no failure of effect.

The weights above mentioned relate to water without admixture of other matter; common water contains in solution heavier matter than water itself, derived from the ground through or over which it runs, and in practice a cubic foot is taken to weigh 62½lb. and to contain 6½ gallons.

In the case of a pipe conveying water from a reservoir to the place where it is to be used, the column of water divides itself into two portions, and the pressure at the lower end of the column is according to the height of the lower portion. The upper portion, being that part of the whole column between the top of the virtual column and the level of the water where it meets the atmosphere, is the head of water, which feeds the column as fast as it descends by the force of gravity. In a pipe of any given diameter, as 1ft., the resistance of the sides of the pipe to the motion of the water is proportionate to its length, for it is proportionate to the area of surface with which the water runs in contact; secondly, it is proportionate to the velocity of the water, for it is proportionate to the number of particles of water in contact with a given length of pipe, as 1ft., during any given time, as one second. But the head of water required to supply the force of which the column of water is robbed in overcoming this resistance must be as the square of the velocity, for not only is it thus simply proportionate to the velocity with which the water moves, but it must be replenished as fast as it runs away. If the length of pipe in contact with the water during one second be twice as great in one case as in another, then there will be twice the resistance due to that cause, requiring twice the head to overcome it, and at the same time the water will run away from the head twice as fast, and require twice the length of pipe full of water to replenish it in the same time.

The head, therefore, is as the square of the velocity. Now as the altitude of the proper head cannot be increased, but remains at the same level, nearly, whatever the velocity in the pipe may be, the only way in which the head can be increased is by taking from the length of the real column the height which may be necessary to give the required velocity—increasing the head at the expense of the real column, and thereby reducing its effective pressure. The same effect may be shown by substituting actual pressures for heads of water, in a horizontal pipe, such as a pumping main. At a point on a line of main be three sections of it be marked off, of equal length, say 1ft., in the direction in which the water flows, and let these sections be numbered 1, 2, and 3 from the point of observation. From the same point let three other sections be marked off, of the same length, in the direction from which the water comes, and let these be called A, B, and C, and let them be bodies of water. Let the diameter of the pipe be such that each body of water requires a pressure of 1lb. to be given to it to overcome the resistance of each of the sections 1, 2, and 3. Then let three operations be performed:

1. A moves through section 1, requiring a pressure of 1lb. 1
2. A and B move through sections 1 and 2, A requiring 2lb. and B 2lb. 4
3. A B and C move through sections 1, 2, and 3, A requiring 3lb., B 3lb., and C 3lb. 9

Then if each operation is performed in the same time, as one second, the pressure required is as the square of the velocity.

If feet vertical of water be substituted for lbs. pressure the illustration serves equally for a head of water.

In respect of diameter: in pipes of different diameters the resistance is inversely as the diameter. The resistance is, indeed, directly as the area with which the water runs in contact, which, in the same length of pipe is as the circumference, and therefore as the diameter, and a diameter of two offers twice as much resistance as a diameter of one; but the distance at which it acts—the radius of the pipe—is twice as far removed from the axis (the point in which there is no resistance), and this, be it remarked, in two opposite directions, so that the effect of distance is as the square of the radius, and, therefore, of the diameter; the resistance being direct in its action, and the distance at which it acts inverse, the result is that the resistance is inversely as the diameter.

These several forces and resistances are formulated thus:—

Let v = velocity per second.

l = length of pipe.

d = diameter.

h = head of water.

$$\text{Then } c^2 = \frac{v^2 l}{d h}$$

in which c is a constant multiplier deduced from experiments to be 2,500 when all dimensions are taken in feet. This is the value of c according to Eytelwein's deduction for long pipes. The velocity, then, in feet per second is $v = \sqrt{\frac{2500 d h}{l}}$ = 50 $\sqrt{\frac{d h}{l}}$; and the diameter is $d = \frac{v^2 l}{2500 h}$. This is the usual

requirement in the case of a pipe to convey water from a reservoir to the place where it is to be used, for in such case the height and length are fixed, and the velocity must be limited so that at its maximum it may do no harm to the pipe by its violence, and so that branches derived from it may be duly filled, and so that a sufficient working pressure be given.

When the pipe is several miles in length the rule is converted into a form expressing the head of water in feet per mile by dividing 5,280 by 2,500, in which l is eliminated, and $h = \frac{2.11 v^2}{d}$. If the velocity be made 3ft. per second, $h = \frac{19}{d}$, and the pressure of water running with that velocity would be, at the distance of one mile from the reservoir, less than that due to the whole height of the column by $\frac{19}{d}$.

It might seem that the pressure would be that due to the whole height less such a head as is required to produce the velocity considered as falling water merely, which would be $\frac{v^2}{64}$; but although that is so in open streams, which are in train, it is not so in pipes under pressure. In this case, as in the other, there is a certain gradient h , e, which, if drawn straight between the head of water in the reservoir and the height due to the pressure at the end of the pipe, is the gradient which that pipe would necessarily take if it ran full, but only full, that is without pressure on the highest part of its circumference; and the pressure at any part of the length of a pipe is that due to the vertical height between the actual position of the pipe and that gradient, which is the "hydraulic gradient." There being thus a gradient line in all conduit

pipes, there must be a length at which there would be no pressure, supposing the pipe to be prolonged so far from the reservoir, and there the water would simply run out of the end of the pipe with the velocity due to the gradient. This length is found as follows:—

Substituting H , the whole head, for h , the head which is due to the velocity v ,

$$l = \frac{2,500 d H}{v^2}$$

For example, let $d = 2$ ft., $H = 100$, $v = 3$,

then $l = \frac{2,500 \times 2 \times 100}{9} = 55,555$ ft. Thus

at the distance of 10 miles or so there would be no pressure in a pipe 2ft. diameter and 100ft. below the reservoir, and it could not carry the water farther than 55,555ft. with a velocity of 3ft. per second; beyond that distance the velocity would diminish, unless an actual gradient were immediately given to the pipe equal to the hydraulic gradient; but that being done, the same velocity would continue to any distance, if the diameter remain the same; the stream of water through the pipe would then be "in train," the forces acting upon it being balanced by the resistances, and it would flow under the same conditions as a river. But if pressure were required, there would need to be either a greater head, a shorter length, or a larger pipe. The conditions to be determined beforehand are (1) the quantity of water required, (2) the pressure required, (3) the height at which it is to be supplied above a fixed datum level; and (4) the height of the reservoir above the same datum.

In one of the examples previously referred to, the quantity of water for supply was found to be 3,000,000 gallons a day, after leaving to the stream one-third of the total available quantity. If the distance at which this quantity were required to be delivered were 5 miles, and the height of the storage reservoir above the service reservoir into which the water would be delivered were 150ft., the following conditions would ensue. The quantity per second corresponding to 3,000,000 gallons

a day is $\frac{3,000,000}{540,000} = 5.55$ cubic feet. If

the velocity be limited to 2ft. per second,

the diameter would be $d = \sqrt{\frac{5.55}{2.5 \times .7854}}$

$= 1.68$ ft., say 21in. The head would be $h = \frac{5,280 \times 5 \times 6.25}{2,500 \times 1.68} = 39.29$ ft., say 40ft. The

effective head would be $150 - 40 = 110$ ft., and the pressure per square inch $\frac{110 \times 62.5}{144}$

$= 47.7$ lb. at the end of a 21in. main 5 miles long.

Upon a line of conduit pipe such as this there may be taken off one or two branches. Say that one-sixth of the water is wanted at three miles distance from the reservoir, and another sixth at four miles, leaving 2,000,000 gallons per day to go to the far end. If the same velocity were preserved throughout, the square of the diameter of the pipe would be reduced one-sixth at the first branch, and one-third at the second. Thus, the first length of three miles being 21in. diameter, the second length of one mile would be 19.18, or, say, 20in.; and the third length of one mile 17.14, or, say, 18in. Each branch takes off 500,000 gallons a day, and, preserving the same velocity, the diameter of each would be $\sqrt{\frac{21^2}{6}} = 8.5$ in., or

say 9in. The effective head in the main conduit pipe at the point where the first branch is derived would be found by deducting the loss of head due to its distance

from the reservoir, three miles, which would be $\frac{3 \times 40}{5} = 24\text{ft.}$, from the difference of altitudes of the reservoir and the branch above the datum. For the second branch the deduction would be rather greater per mile, the diameter being less, while the velocity is the same, for the head is inversely proportionate to the diameter, according to the formula $chd = v^2 l$. Thus if the loss of head due to a velocity of $2\frac{1}{2}\text{ft.}$ per second in the 21in. pipe be 8ft. per mile, it would be in the 20in. pipe $\frac{21 \times 8}{20} = 8.4\text{ft.}$ per mile, and in the 18in. pipe $\frac{21 \times 8}{18} = 9.4\text{ft.}$ per mile. Adding together the losses of these three lengths—viz., for the first three miles, 24ft. , for the fourth mile, $8\frac{1}{2}\text{ft.}$, and for the fifth mile, $9\frac{1}{2}\text{ft.}$, the total loss at the end of the five miles would be 42ft. , instead of 40ft. , as it would be if the full diameter were continued to the end, and the quantity delivered were $3,000,000$ gallons a day.

ARCHITECTURAL ASSOCIATION.

THE first ordinary meeting of this Association for the present session was held on Friday evening, the President, Mr. Aston Webb, in the chair. In opening the proceedings the PRESIDENT remarked that it was usual to take the annual report and balance-sheet as read. Was that the pleasure of the meeting? Mr. BLASHILL said he had very great pleasure in moving their adoption. At the same time, he must congratulate the Association upon the great advance, the extremely great advance, in the number of members which had taken place, and on the great increase in the amount of work done by the Association.

The Annual Class Reports, instead of being read *seriatim et verbatim*, as in former years, were also taken as read, being printed and distributed in the room—an innovation which considerably curtailed the preliminary business, and allowed of more attention being given to the address. The report spoke of work done as considerably above the average in quality, but generally complained of the scanty attendance at the classes in proportion to the largely augmented numbers of members in the Association. The exception to the latter rule was the Elementary Class of Design, in which the members had increased by 50 per cent., and the number of designs executed had been more than doubled.

A list of 63 nominations of intended members was read amidst applause, and a general vote of thanks was, on the motion of Mr. Eales, hon. secretary, passed to the entertainment committee, exhibitors, and all who assisted in making the opening *conversazione* a success. The PRESIDENT mentioned that he had received from the Chairman of the Working Men's Club and Institute a letter asking that some of the members should conduct parties of working men over buildings in progress on Saturday afternoons,—a proposal which the President said would tend, if carried out, to bring about a good feeling between architects and artisans. The PRESIDENT then delivered

THE INAUGURAL ADDRESS.

This was arranged under two heads—the first part dealing with matters of immediate interest to members of the Association, the second with the more general question of architects' education and training. Having detailed the new arrangements as to classes rendered desirable by the compulsory examinations, which now guard the admission into the Institute, the President mentioned that the special courses of lectures on Design and Construction, to be given by Messrs. Tarver and Blashill, would not be in any sense of a "cramping" character. While the quality of the work done in the classes was good, it was unsatisfactory that no more than about 120 out of their 860 members were working in the classes, and the aims and objects of the Association were not at present fully achieved. The necessity to attend classes regularly and to systematise study was now more urgent than ever, for, as Professor Roger Smith had observed, the law of the "survival of the fittest" was inexorable in the profession.

Having reviewed the condition of the library, the annual excursion, and other auxiliary features of the Association, the President remarked that students were now well supplied with encouragement in the form of prizes. Besides the very valuable ones offered by the Academy and the Institute, this Association awarded nearly £70 a year in this way, including the recently-founded travelling studentship. It was to be regretted that the competitions for these prizes were not keener, and that many members who worked well in the classes were too diffident to enter the lists for the rewards. Unless there was an improvement in this respect, it would be a serious question with the committee whether the money now expended on the Association medal could not be better utilised. While criticising these matters, he also thought there was room for great improvement in the discussions at their fortnightly meetings, where the speaking was almost always left to a few senior members. Opinions, except in the matter of traps, were not now held decidedly nor freely discussed. The spirit of liberalism seemed to have spread from religion to art, and men were inclined to think that while their own views were possibly right, they should be equally ready to admit that directly contrary ideas might also be correct. Mr. G. E. Street, in his opening address at the Institute, had very kindly alluded to the Association, expressing further a decided opinion that some means might and ought to be devised for enabling "that active body" to join the Institute. The proposition was not by any means broached for the first time; but coming from Mr. Street, it demanded fresh consideration. Speaking for himself, he did not think that any one was hindered from joining the Institute or working in it by membership in the Association; indeed, he found from the "Brown Book" that six of the members of the Association sat at the Council of the Institute, whilst 51 were fellows, and no fewer than 170 associates of that body. He thought that members of the Association did take part in the affairs of the Institute whenever they could be of use; that they should speak much at the meetings of that body was hardly to be expected, or perhaps desired. Should any scheme be submitted in furtherance of Mr. Street's views it would receive careful attention; but the system on which the work of the Association had been gradually built up, had succeeded so well, and the prosperity of the Institute had also been so largely increased that, for himself, he believed they supported the Institute more in an independent position than would be possible in any other way, and that the present arrangement would become still more useful in the preparation of students for the membership examination. Each body had a work of its own—the Institute as the representative professional body before the world; the Association as the educational and preparatory society.

He would now pass on to consider in detail his second and more general topic, viz., how could his opportunities best be utilised by a student entering the profession? Ample as were the educational advantages of an architectural pupil, his training was of a most haphazard, disjointed, and altogether inadequate nature, quite unfitted to prepare a man for the intricate and ever-increasing duties of the profession. At present all the subsidiary means of education, beyond those of a practical kind supplied in an architect's office, were to be had only in the evening, when the pupil, if he had worked hard all day, could not bring a fresh intellect to bear upon his tasks. What was wanted was a college or school where a student could spend one or two years in systematic and theoretical education before entering an architect's office. But taking the means of education as they existed, the London pupil should follow some such course as this. In the first year he should attend the Elementary Class of Design, and read at home such books as he was recommended and could obtain. In the second year he should join the Class of Design, and also that of Construction, aiming at a prize in one of them; during his holidays he should spend part of the time in sketching, and publish some of the results in the A.A. sketch-book. In the third year he might with advantage attend the lectures at University or King's College, in addition to either the Class of Construction or Design at the Association; he should also compete for the measured drawings

prize. In the fourth year he should become a student at the Academy, join the Colour or Advanced Construction Class, and compete for the A.A. Travelling Studentship. In the fifth year he should work at the Academy and at one of the Association classes, probably as one of the officers, and compete for the Pugin Studentship or Soane Medallion. After this he should take a trip abroad, and on his return compete for the great prizes offered at the Academy. At the same time he has gone into a rather office for further experience, or has commenced practice on his own account. Such a curriculum would vary with circumstances, but if students laid down for themselves some such order of study and worked to it from the commencement, they would find the various opportunities more useful to them than they were at present. This question of education affected the tone and attainments of the profession as a whole, and had much to do with its influence upon the public. Another matter of interest at the present time was, as to how far the archaeological side of the art had too much engrossed attention, and how far it should form a portion of architectural education? Archaeology to architecture was as grammar to language, and without a knowledge of styles and their history and sequence, design was impossible. The originality now so much aimed at was never evolved from ignorance of what had already been accomplished. Archaeology, while a *sine qua non* to the student, could yet be carried too far, and, directly a young man made notes of detail for the purpose of "working them in," he left his position of designer for that of copyist. The great movement for church restoration led to much of this archaeology, and was, perhaps, responsible for the general want of originality, and for the present lack of enthusiasm in the art. The principal questions of the day for architects were of a negative character; "We ought not to restore any more churches." "We ought not to take out our own quantities." "We ought not to go into competitions," and the *British Quarterly* had laboured to prove that "We ought not to have too much work to do." None of these questions were likely to stir up much enthusiasm. The Anti-restoration movement was started only when restoration was almost drawing to a close. Opinions as to taking out quantities seemed very evenly balanced, for those who took them out saw no harm in it, and those who did not thought it better to leave quantities alone. The competition question had been laid to rest by an almost unanimous expression of opinion in favour of the appointment of a referee—an excellent arrangement, especially for the referee. The *British Quarterly's* complaint that pluralism was the crying evil, was certainly not the special grievance amongst architects generally. Recurring to an earlier subject, the place of archaeology in art training, he thought students required, in addition to a thorough knowledge of previous styles and edifices, a more careful study of the best buildings of our own day, and an effort to avail themselves of modern improvements and inventions as they were brought forward. For example, Sunday-schools and middle-class private schools afforded a large field for improvement and ingenuity in planning, while the adaptation of sanitary improvements to the architectural treatment of our houses was another matter yet to be satisfactorily dealt with. Water-colour sketching, and the design of furniture or carpets, however enticing, were not part of the real work of architects. There was an art of great opportunities, and no matter how small or insignificant a work might appear, if designed with thoughtful care it must possess an individuality of its own, and must be of enduring interest to others. In conclusion, the President quoted a stirring sentence from Carlyle, urging the student to be up and doing, and to work with all his might.

Mr. J. DOUGLASS MATHEWS proposed a vote of thanks to the President for his practical address. He quite agreed with his views as to the suggestion so courteously expressed by Mr. Street, for a fusion of the Institute and Association. It was not surprising that the vigour and progress of the latter body should attract attention in the more august assembly upstairs, and that they should wish it to be united to their own society. He trusted, however, that such a decided expression of opinion would go forth from the members that the idea would be dropped. (Applause.) The very success of the Association had been its perfect freedom, its

self-government and independence, and any attempt to connect them with another society would introduce the feeling of being overlooked in their work. At the same time the two bodies were in perfect harmony with each other; by their class arrangements in preparation for the examination, the Association had shown that they recognised the intention of the Institute, and wished to act so as to support it. While, therefore, preserving their independence and freedom, they showed that membership of the Institute was the intended "goal"—(laughter and applause)—no, goal of their members.

Mr. BLASHILL, in seconding the motion of thanks, said their President's sober advice as to a curriculum for architectural students must prove of great use to the younger men. Like the previous speakers, he should regret if the kindly meant suggestion of Mr. Street for a fusion were carried out. The more gentlemen connected with the Institute made themselves acquainted with the history, scope, and work of the Association, the more clearly would they see the impracticability of the proposal. At the same time, they were in true harmony with the Institute. Many years since there was some antagonism manifested, and the Association flagged as a consequence. A new committee was elected with fresh blood, the desire being more amicable relations with the Institute, and from that time, exactly one-and-twenty years since, the progress of the Association had been uniform. As one of the new members of committee appointed at that time, he had considerable interest in recalling the facts.

Mr. E. C. LEE (ex-President) supported the good advice to young men offered in the President's address, and cordially congratulated him on the prospects of the session.

Mr. LACY W. RIDGE trusted that the Association would possess her soul in perfect confidence as to the suggested fusion. It was an amiable idea likely to occur to Mr. Street as he surveyed the world for the first time from the throne of the Institute; but it would never, he would predict, come forth from the room in which it was mooted. The feeling even of the Council of the R.I.B.A. would be so opposed to making another offer that the Association need not be perturbed. It was not only true, as Mr. Webb had shown, that the Association had been an important feeder to the higher body, but it was about to organise a still greater aid in sending up young men well prepared for the compulsory examination.

Mr. J. A. GORCH said he should have liked to have heard some suggestions as to the problem of a new style. He wished to see a really satisfactory conservatory, an æsthetic cloak-room, and a perfect skylight. The curriculum sketched by the President was an excellent one, but the common complaint amongst senior architects was that the young men were too apt to make the theatre and the restaurant their places for evening study.

Mr. H. H. STANNUS thought Mr. Street's suggestion had been misunderstood. It was not a mere "amiable idea" for a fusion, but a distinct scheme for permitting delegates elected by that association and kindred bodies in Manchester, Leeds, Birmingham, Edinburgh, &c., to sit at the council of the Institute, and assist in their deliberations. That was a very different matter, and in his opinion quite practicable.

After some remarks from Mr. SYDNEY VACHER, on the desirability of framing, in committee, with legal assistance, a satisfactory model agreement for articled pupils, Mr. S. F. CLARSON put to the meeting the vote of thanks, which was carried by acclamation, and was suitably acknowledged by the President.

LECTURES ON HORTICULTURAL BUILDINGS AT THE CRYSTAL PALACE.—I.

A COURSE of three lectures on the "Construction, Fittings, and Heating of Green-houses and other Horticultural Structures," illustrated by numerous diagrams, models, &c., is being delivered on successive Wednesday evenings, by Mr. F. A. FAWKES, of 4, Queen Victoria-street, E.C., author of "Horticultural Buildings," before the members of the Crystal Palace School of Gardening and the public. Of the first lecture, given on Wednesday, the 16th inst., at 5 p.m., we publish to-day a report.

In his opening remarks the lecturer mentioned that he proposed to explain in these lectures some of the principles of horticultural construction and the modes of applying these principles to practice, and that he should leave to others the consideration of everything having reference to cultivation proper. He would first give a few general hints on the designing of green-houses; then he should discuss some scientific facts which it was absolutely necessary to know; next he proposed to look at each class of green-house; and finally attempt an analysis of some of the details of construction. If you are consulted regarding the erection of, say, growing-houses, obtain, the lecturer observed, a clear idea what and how much is required to be grown, and, if possible, the amount of money

them to be erected in a substantial, efficient manner, you find they will cost more money than is at immediate disposal. It is better to dispense with the two outer lean-to's for the present than risk the ruin of the whole range by either making all the five lean-to's smaller or else sacrificing materials and workmanship. Never attempt to cover the maximum area at the minimum cost. The variations of temperature to which horticultural buildings are exposed necessitate greater care in choice of materials and in working than almost any other description of buildings. When the houses are built the designer's moral responsibility does not end; in planning, the question of the amount of labour which can be subsequently spent in them must not be lost sight of. It is preferable to build a given quantity of glass with the certainty that it will be efficiently and carefully worked afterwards, than to build double the quantity with the possibility that it will be neglected.

Since the form, the position, the proportions, and even the dimensions of glasshouses depend upon the sun, it is of primary importance that we have clear ideas about the sun and sunlight. You are all aware that the sun does not rise exactly in the east and set exactly in the west, nor does it attain the same altitude all the year round. In point of fact, the sun on the shortest day rises about 50° east of south, attains a height of about 15° above the horizon, and sets about 50° west of south. On the longest day it rises about 50° east of north, attains a height of about 62° above the horizon and sets about 50° west of north. The sun thus occupies between the longest and the shortest days positions between the two points indicated. Thus Fig. 1 gives the angle of the sun's maximum altitude during the longest day; Fig. 2 maximum altitude on shortest day; Fig. 3, the points on the horizon of the sun's rising and setting on the longest day; and Fig. 4 similar points for the

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 5.

FIG. 6.

proposed to be expended on the houses. Examine all the contingent conditions, such as aspect, site, soil, drainage, levels, most suitable dimensions and combinations of houses, position of boiler, and necessity for subsidiary buildings, such as potting-shed, tool-house, fruit and seed-rooms, &c. Having grasped the situation, you can, with the greater likelihood of success, commence planning the required houses. If, after you have formulated your plans, you find the cost requires to be reduced, you have three courses open to you: you can retain the dimensions, but cut down the cost of workmanship and materials—a fatal policy; or you can reduce the dimensions of your houses, retaining the same workmanship—a better course to pursue; or the plan may remain, but part only of the work be carried out. If your plans represent necessary erections, the last is by far the best course to pursue. Suppose, for instance, that a range of five lean-to houses must be built, and that after you have planned

shortest day. In these diagrams the morning sun always occupies the right-hand side and the afternoon sun the left-hand half. Farther, when the sun's rays strike a sheet of glass, some of the rays cannot pass through, the proportion of obstruction depending on the angle at which they impinge on the glass. The more nearly the impinging rays approach a right angle the smaller is the proportion of light lost in transmission, and it is therefore important that one glass roof shall be set at as nearly right angles to the sunlight as possible.

We must now pass on to consider the forms of simple growing-houses and the reasons for their assuming these forms. The first and most natural form is the lean-to, which is shown on four of our diagrams: Fig. 5, a lean-to with

front lights, and Fig. 6, a forcing-house without these adjuncts; Figs. 7 and 8 illustrate

Fig. 7.

Fig. 8.

sections of wall tree covers. The lean-to is used when a wall or building already exists against which it is desired to place a house; when a wall is specially built to give protection on north and allow of houses facing the south; when the exigencies of plants need it; when the maximum length of rafter is required; or when, with an existing wall, a house having a given area is wanted at the smallest cost. Other things being equal, a lean-to is easier to heat than a span-house. The best position, of course, for a lean-to is facing south; but even then, with a

Fig. 9.

Fig. 10.

wall at rear running east and west, part of the early morning and late evening sun will be lost during part of the year. If the wall does not face south the morning or evening sunlight will be lost in exact proportion to the inclination towards west or east.

The next simple form of house is the span, of which Fig. 9, a section of an ordinary plant-house with side lights, and Fig. 10, a section of orchard, fruit, or large plant-house (the letters A A indicate casement to ventilators), are examples. This form is used where no high wall

Fig. 11.

exists or is required, for building at right angles to and in combination with a range of lean-to houses against a south wall; when the minimum height is required, so that there may be as little obstruction as possible; when plants require to be within reach, but yet as near the glass as possible; when great length of rafter is not necessary; when the length of house requires to be north and south, and each side needs an equal sunlight. The last-named position, with ridge running north and south, is thus the best for span-houses, but they are sometimes built east and west to accommodate plants requiring various degrees of light. A popular form of greenhouse with nurserymen, is a span-house about 11 ft. wide, somewhat similar to Fig. 9 already referred to. Fig. 11 shows a compromise between lean-to and span, very useful when the back wall of an otherwise lean-to requires to be kept as low as possible; or when it is necessary to let light in at the back, or when the maximum length of rafter is not a *sine qua non*; when a certain inclination of roof

Fig. 12.

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

is required without altering an existing wall; or when, for architectural purposes an ornamental ridge is advisable, yet the house needs to approximate to the lean-to form. Except as meeting some of these special requirements, or in combination with other houses, three-quarter houses are somewhat ugly.

The most complex arrangement of houses may be split up into one of these three forms, the lean-to, span, or three-quarter span. The same principles regulate a single house or a number used in combination. When several houses are required they should be planned in as compact a mass as possible, with the buildings for consecutive operations placed in consecutive order, with no long undivided houses, so that the boilers are in a convenient position, and so arranged that no building suffers in efficiency through its combination with others.

The site next claims attention. Care must be taken that no trees or other objects obstruct the sun's rays. If the ground be not level, ascertain the direction of fall: if it is in the direction of the length of buildings, the site must be levelled. Figs. 12, 13, and 14, show various methods of levelling, and Figs. 15, and 16, incorrect methods of effecting the same end. The boiler should be, where possible, at the lowest end of site, so as to lessen the amount of excavation. Even supposing the ground is horizontal, the question of floor-levels must be considered, as these must be raised, if there is a difficulty of drainage, or of sinking the boiler to required depth. It may be requisite to sink the floor-line to reduce the obstruction that houses occasion; but in that case great pains must be taken with the drainage. The old plan was to sink all greenhouses, in order to retain as much heat as possible; but with greater facilities for heating this is unnecessary, and to sink the floor increases the cost of the work. Houses comprising one range should, if possible, have their floors on the same level. Parallel disconnected lines of houses may be placed, if necessary, on different levels.

The first and most important part of the construction is the proper pitch of roofs. In order to receive the sun's rays within 10° of a right angle at noon, for 16 weeks before and 16 weeks after the longest day, the roof must, in London, be inclined at an angle of 37° from the horizontal, adding 1° for each degree north, and subtracting 1° for each degree south. In most cases, however, for growing purposes, a lower pitch economises space and artificial heat, and is really more advantageous, a pitch of from 26° to 30° being very suitable. This angle of 26° is equal to a rise of about 6 in. to the foot, one of 30° to 7 in., of $33\frac{1}{2}^\circ$ to 8 in., of $36\frac{1}{2}^\circ$ to 9 in., of 40° to 10 in., of 43° to 11 in., and 45° to 12 in. rise vertical per horizontal foot. For fruit-growing along the rafters from 36° to 40° , would be a suitable pitch, for plant-growing in low houses, from 26° to 30° , and for wall-fruit cultivation, where a narrow, high pitch is advisable, from 65° to 70° may be suitable. With the same width and the same pitch, a span and a lean-to roof contain the same area.

In constructing the roof of a glasshouse three points must be remembered: 1st, obstruction to sun's rays must be avoided as much as possible; 2nd, yet the roof must be solid and substantial; whilst, 3rd, lateral thrust must be avoided. The rafters must be sufficiently deep to sustain the roof, but not so deep as to materially obstruct the light. The lecturer exhibited diagrams of several plain, cheap, forms of roofing, in which iron ties were introduced. For narrow houses iron brackets can be used at wide intervals; but for wider ones, up to about 13 ft. wide, a truss formed by tie-rods and a king-post is suitable as admitting of a very shallow rafter being used. In wider roofs two sets of tie-rods, one to prevent outward thrust, the other to protect the rafters themselves from bending, are necessary, and furnish a remarkably rigid form of roof. Internal pillars are only required in a large house or winter-garden; when introduced into a span-house of 12 ft. or 14 ft. width they evidence improper construction, and would be awkward obstructions in use. The ties for the king-post and double-trussed roofs may be wrought-iron rods, $\frac{3}{4}$ in. to $\frac{1}{2}$ in. in diameter, according to width of house, and should have eyes for bolting to the king- and queen-posts and brackets. All the brackets should be securely bolted to the woodwork. In such a structure the rafters may be from $3\frac{1}{2}$ in. to 6 in. deep; the sash-bars, 2 in. by 1 in.; the mullions, $3\frac{1}{2}$ in. by $\frac{1}{2}$ in.; and the lights, 2 in. The intermediate spaces between rafters may be of framed sashes, the side of each resting on half each rafter, or simple sash-bars may be employed to fill up the intermediate spaces. These sash-bars, although they rest on a plate at top and bottom, require

to be supported by purlins, either of wood morticed into the rafters, or of T-iron, when the mortices will be less weakening to rafters. Not only are the upright sides of some houses formed by sashes, but also the ends and partitions. The advantages are that a house can be taken to pieces, removed, and re-erected without taking the glass out. For ordinary cultivating purposes, however, the "sash" construction is rapidly going out of fashion in favour of the "sash-bar," as the latter is simpler, cheaper, affords less obstruction to light, and less wood-work to rot or harbour insects. This suggests the question, Is iron better than wood, or not? As it is desirable to employ a minimum mass of materials consistent with strength and durability, iron is far preferable, in this respect, to wood. It is also more durable, if well painted; if painting be neglected it will rust, damage the plants, and wear out. On the other hand, iron houses are more costly than wood; heat is conveyed away from the interior rather more rapidly; and unless the glass is carefully put in, it is apt to crack. For these reasons, for growing-houses, wood is preferred to iron. Copper has been used for sash-bars: it is much better than iron, but proportionately more expensive. If wood be used, it is extremely necessary that it be thoroughly seasoned, on account of the varying temperature within and without, and the exposure. If the wood is not well seasoned, cracks will soon appear, in which moisture and insects will be harboured, and the house will soon become useless.

In concluding his first lecture, Mr. Fawkes mentioned another treatment of materials—namely, a happy combination of wood and iron. If the plates, sills, mullions, in fact the absolute skeleton, be made of wood, and the sashes and intermediate sash-bars be made out of a suitable section of T L and sashbar iron—although such a combination may not be usual—the result will be a very light, strong, serviceable house, which will receive the sun's rays in a very advantageous manner.

(To be continued.)

SOME NOTES IN THE WEST.

"DOWN-ALONG" in the far west, the principal Cornish work in hand is undoubtedly the new Cathedral Church of St. Mary, at Truro. The crypt, which in its noble proportions reminds one of that of Glasgow, is fast assuming a tangible form. The eastern wall is 15ft. above the floor-line, and has all its windows and arches fixed. The other walls average 8ft. 6in. above the floor, and have the jambs of their windows in place. The staircase leading to the north and south choir-aisles, is up level to the aisle-floors, and some of the bases of the piers in the choir-aisles are *in situ*. All the piers and capitals, and most of the solid groin springer stones are up—the two easternmost piers of the great central tower are now 11ft. above the floor-line. The concrete forming the floor of the crypt is, of course, all in to its proper level. In every instance, the solid rock was found before putting in the concrete; in places this was 20ft. down. It will be remembered that Mr. J. L. Pearson, R.A., fought hard for the preservation of the ornate south and east wall of the old church of St. Mary, and ultimately carried his point. Incorporated in the grouping of the new building, this will necessarily form an interesting archaeological feature. It has been underpinned, and is now being carefully restored. This is a delicate and withal a somewhat dangerous task; but is in good hands, for there are few, if any, better qualified men in England for the post of managing clerk of works than is Mr. James Bubbs. Up to the present moment, Mr. Pearson has carried out the whole of the works, without a contractor, and under the practical and personal superintendence of his trusty representative, Mr. Bubbs. There is a staff of about 70 workmen employed upon the works, Mr. Dan Delafield being foreman. It speaks well for the good management of Messrs. Bubbs and Delafield, to record that although at the commencement, the old church and its spire, together with 21 houses were removed, everything has been done then and since without the slightest accident—during the whole progress of the works there has not been so much as one crushed finger. The Bishop of Truro is by no means a

mere theoretical man. At the consecration of a church in his diocese, recently, he said, that, as a youth, he learnt to work as a carpenter, that he had also tried masonry, and had many a time handled a trowel and put up brick-walls. "The clergy as a rule," he added, "got their knowledge of such like work from an encyclopedia, but his was a practical experience." And such being the case, he argued that he understood, and could sympathise the better with working men. All who know Bishop Benson agree in affirming that he is by no means a "bad sort!"

There are few more picturesque places in all England than Fowey. The church, dedicated to St. Finbar, was restored some few years ago by Mr. J. Piers St. Aubyn. The building contains some fine monuments: Upon one of them in the north aisle is some exceedingly handsome carved Elizabethan work. It dates from A.D. 1582, and the quaint inscription thereon may be worth while recording, it runs:—

"John Rashleigh lived years three score three
And then did yield to die—
He did bequeath his soul to God
His Corpse here-in to lie.

"The Devonshire house, yet Rashleigh's height—
Well sheweth from whence he came
His virtuous life in Fowey town
Deserveth endless fame.

Lanyon he did take to wife, by her had children store,
Yet at his death but daughters six, one son, he had no more—
All them to partake under here, because fit space was none,
The son, whose only chance this was, is therefore set alone."

As a memorial to the late Vicar (Rev. Dr. Trefry) the whole of the clerestory windows of this church are to be filled with stained glass. The work is being executed, by Messrs. Fouracre and Watson, of Stonehouse, Plymouth, and will be shortly complete. The subjects (with one exception) are Cornish saints, and some delay has been occasioned by the difficulty of ascertaining the correct history of several of the ancient worthies whom it is desired to picture. Cornish hagiology is rich and varied, and as proportionately obscure. The antecedents of even so popular a saint as St. Austell (who is to fill one window) is a theme of no little contention between martyrologists and archaeologists. Some affirm that he was a bishop named Austulus, others consider that Auxilius, a disciple of St. Patrick, is entitled to sponsorship, while Mr. Borlase, whose book on Cornish saints is no mean authority, declares a maiden named Hawystil to be the true St. Austell. Of St. Ildierna, the patron saint of Lansallos church, of which Dr. Trefry was sometime rector, absolutely nothing appears to be known.

From the tower of Budock Church, near Falmouth, three bells, dated A.D. 1664, were removed last week by Mr. Aggett, the church bell-hanger of Chagford. They are to be re-cast into a peal of six, in the key of G. Mr. Aggett will also fix an apparatus, so that the whole peal may be chimed by one person.

Mevagissey is a fishing town upon the Cornish south coast. The Burial Board recently advertised for a clerk. There were three applicants, and the economical board have just accepted one of them (Mr. R. Skinner, late chief boatman of the neighbouring coastguard) at a salary of £5 per annum!

The awful wreck of the *Schiller* is always associated with the name of the Scilly Isles. It is satisfactory to report that the Government have just decided to place a powerful steam fog horn at Scilly, as some warning to vessels nearing the land from the south west. The edifice for the reception of this horn will probably stand upon the island of St. Sampson, and it is anticipated that the works will be commenced next summer.

Talking of lighthouses reminds us of the remarkable accident that occurred at the New Eldstone last week. This celebrated erection stands upon a rock, out in the English Channel some ten or twelve miles from Rame Head. The first lighthouse there was built in 1696, the next in 1709, and the present one in 1759. The new one stands upon another rock close by. The glasswork in its lantern is complete and the fabric, therefore, in its exterior appearance is now perfected. The distance from land has rendered it necessary for the men employed to work on the rock in weekly shifts, and these working parties have, throughout the whole time, been under the personal superintendence

of Messrs. Edmond and Douglass, the engineers, who have done the duty alternately. Last week Mr. Edmond was at the rock, and on Saturday at noon, the weekly relief was effected as usual.

The out-of-the-way and somewhat interesting church at Sancreed lies half-way between Penzance and the Land's End. It was reopened, after restoration, a few weeks ago, when a curious error crept into the local papers, and was, afterwards, duly copied by some of the professional ones. It was that, according to Mr. Sedding, the architect's opinion, this church at present possessed the finest old rood-screen in Cornwall. Now, Devon and Somersetshire, as every reader knows, are rich in ancient rood-screens, but once the traveller gets westward of the Tamar, these partitioned between nave and chancel become conspicuous by their almost entire absence. At Lanivet, near Bodmin, are the remains of the lower portion of a good rood-screen. These fragments now do duty as a dwarf-screen in the tower arch. At a few other churches, similar remains may be met with. Amongst these may be mentioned Sancreed. Two old pieces of framing, one 8ft. 9in. and the other 7ft. 6in. in length, and each 2ft. 9in. high, exist there. They are curiously carved, and once, probably, formed the lower panelling of an ancient screen. There was nothing more, and hence, Sancreed can have no claim whatever to boast of any architectural specimen of the sort in the superlative degree. The most complete old screen in the West, a rare example of the groined screens of the Perpendicular period, exists at St. Ewe, near St. Austell. Having fallen into a sad state, it has, during the present summer, been carefully renovated by Mr. Harry Hems, the Exeter carver, under the immediate supervision of Mr. J. Piers St. Aubyn, the well-known architect, of London. This is the finest old rood-screen in Cornwall.

At Liskeard the new board-schools are making rapid progress towards completion. The roofs are covered in, and the interior work is in a forward state. Local stone is used for the walling, and the window and door dressings are of Portland stone and grey granite. The designs were won in competition by Messrs. Webb and Pearce, architects; Mr. Sampson Treharne, of Liskeard, is the builder. His contract price was a little over £2,000.

Talland Vicarage, near Looe, is being considerably enlarged from the designs of Mr. A. E. Skentlebury, architect, of East Looe. The site commands charming views of the rugged coast and of the adjacent Channel. The contractor is Mr. S. Dawe, of West Looe, the plumbing is by Mr. Strong, of Liskeard, Messrs. Minton, Hollins, and Co. have supplied the tiles, and Messrs. Barnard, Bishop, and Barnards, of Norwich, the various grates, &c.

The competition for the East Looe church rebuilding is not at all likely to turn out a professional plum, with the risk of putting one's thumb into the conventional pie. A good local architect, Mr. Skentlebury, lives at Looe, and being a parishioner, might well have been entrusted with the job. But that did not suit the committee. Designs were advertised for, and thirty odd sets were duly sent in. A London architect, under the *nom-de-plume* of "Britain," we hear, is awarded the prize. And what is it after all,—5 per cent. on a £2,000 job, and no travelling or any other "extra" expenses to be allowed. East Looe is 6 miles from Menheniot, the nearest railway-station, and a second-class return ticket to this latter place from Paddington costs 55s. And, letting alone the expense, a journey from London to East Looe and back involves travelling a distance of 331 miles.

We had intended touching upon several works in progress in the neighbouring county of Devonshire, but of this space does not admit. Those notes are therefore held over until next week. II.

LEEDS ARCHITECTURAL SOCIETY.

THE first ordinary meeting of the members of this society for the present session was held last week. Mr. James Barlow Fraser, F.R.I.B.A., the president, occupied the chair. Eighteen new members were nominated.

Mr. W. H. Thorp, the honorary secretary, read the annual report, which was adopted.

The President said: It is a matter for congratulation that our society has, during the five years of its existence, been constantly gain-

ing ground, by strengthening its position and extending its influence among all classes of society. This gradual development has rendered necessary an entire change in our constitution, which you have carried out with great judgment; and I believe the effect will be that all our members, as also the general public, interested in the study of architecture and the collateral arts, will take even a deeper interest in our welfare than they have hitherto done, seeing that we now specially invite our friends outside the profession to be present at our meetings; and by such intercourse we earnestly desire to assist and impart to the public a more correct appreciation and knowledge of all matters connected with architecture, and the difficulties architects have to contend with, than has hitherto been prevalent or possible. I trust that the reconstitution of our society may bring about all the results that we desire, including the means of checking many abuses which we unfortunately know do exist in the outside ranks of our profession, and which may to a certain extent be stamped out by our united moral influence. Let us make the best use of this power and exert it to the fullest extent, and I trust the time is not far distant when we may be placed on the same footing with all other learned professions; and, as a preliminary step to this greatly desired legislation, the voluntary examination conducted by the central corporate body for so long a period must have had the effect of proving to our legislature, if such proof were considered necessary, that we are in earnest, and desire most seriously the establishment of compulsory examination with a diploma. We will now take a brief glance at our profession as represented by the various institutes, associations, and societies throughout the United Kingdom, commencing with the Royal Institute of British Architects, which, as you know, has held a charter for upwards of forty-four years. There are also sixteen other societies, including and similar in composition to our own in Leeds, and having the same objects in view. The number of members of all classes, exclusive of honorary members, attached to each society, is as follows:—

Years in Existence.	Total.
47 Royal Institute of British Architects, of which 559 are London members	861
39 Architectural Association of London, of which 691 are London members	863
20 Architectural Institute of Scotland, . . .	24
23 Edinburgh Architectural Association	120
13 Glasgow Institute of Architects	50
23 Glasgow Architectural Society	47
4 Glasgow Architectural Association	30
41 Royal Irish Institute of Architects	56
37 Liverpool Architectural Society	101
13 Manchester Society of Architects	30
8 Manchester Architectural Association	66
23 Northern Architectural Association	34
38 Associated Architectural Society (includes seven associations), Lincoln	12
8 Leicester and Leicestershire Society of Architects	31
6 Birmingham Architectural Association	27
19 Nottinghamshire Architectural Society	12
5 Leeds Architectural Society	70
	2,428

Thus it will be seen the total number of members of all classes comprised in the seventeen associations, including the London, Edinburgh, and Glasgow Institutes, is 2,428. If you deduct the 302 provincial architects who are also members of the Institute, you will find the full representation of our profession by means of these societies, including assistants, is 2,126, or about one-seventh of the total number of practising architects and assistants in the United Kingdom; but if you will take the 559 London members of the Royal Institute of British Architects, you will find that they form about one-fourth of the aggregate of the sixteen associations, and only about one-twenty-seventh of the entire number of architects and assistants. We cannot consider this a satisfactory state of things, whether with a view to our mutual advancement in all matters pertaining to the profession or with regard to our representation by the Chartered Institute in London; and until our numbers are increased fourfold we cannot expect to speak with sufficient authority for the whole body of our profession. The Leeds Architectural Society ranks well,

taking the third position amongst its compeers in the provinces, Liverpool occupying the first place, and Edinburgh the second; but we must not feel by any means satisfied until our roll of members is trebled, and I do not doubt the attainment of such a position if each member will make its accomplishment a personal matter, having in view not only the welfare of our society but of the profession at large.

Turning to the doings of the past twelve months, we may congratulate ourselves that our art is still gaining ground, both in the estimation of the general public and in the class of work produced. Certainly a more refined and commendable spirit in the treatment of detail is making itself apparent, and a decided reaction has set in against the crudities and eccentricities of the extreme Queen Anne school. Not that I am by any means disposed to condemn the much abused and also much lauded style altogether. I think the vigour and piquancy inherent in the style have done much to give force and originality to the efforts of our younger architects, and specially the introduction of bright warm colours into our dull atmosphere is a matter of thankfulness. The æsthetic craze (as it is sometimes called) of recent years, although absurd enough in some of its features, has been of much practical use in calling the attention of our prosy and matter-of-fact business men and women to the possibility and desirability of combining refinement with the solid comforts of home life; and all who like myself can contrast by aid of their memories the furniture and general finish of the interiors of our middle-class homes of thirty years ago with those of to-day, will, I am sure, agree with me that a wonderful stride has been made in public taste in the right direction in all matters pertaining to domestic art. Whilst joining in the laugh against the vagaries, sublimities, and too-too-ites of the Maule and Postlethwaite school, and enjoying to the full the keen satire of Du Maurier, Burnand, and Gilbert, in describing their follies, one cannot help admitting that the sad colours and strange decorative devices adopted and advocated by their "supreme intensities" have resulted at least in some improvement over the stereotyped ornaments, crimson paper, crimson curtains, crimson carpets, and general glare and hardness thought to be the acme of respectability and luxury when we were schoolboys. No great advance has been made, and no startling innovation has, to my knowledge, been adopted in connection with sanitary science during the last twelve months; the all-important question of the health of the people, both individually, in their several homes, and as component parts of populous cities, continues, however, to receive the careful attention of public authorities and the members of our profession.

There appears to be room for improvement in the design of our railway bridges and viaducts and other structures, which are left entirely to the civil engineer, with the result that (so far as the brick and stone work, at any rate, is concerned) the same features and methods are adopted as those of forty or fifty years back. Some of the old county bridges, designed in bygone days, when the callings of architect and engineer were nearly always combined, are models of beauty and form, united with strength in construction, and it seems a pity that something of the same feeling cannot be incorporated into our present work.

The President then went on to refer to many recently erected buildings in Leeds and the neighbourhood, and concluded by insisting on the importance of frequent sketching, and attention to sanitary matters on the part of the young members of the profession.

THE SURVEYORS' INSTITUTION.

A CROWDED audience assembled in the lecture hall of the Institution on Monday, to hear the opening address of the president, Mr. Edward Ryde. The occasion was one of special interest, being the first meeting of the Institution since its incorporation by Royal charter. The president referred in terms of congratulation to the prosperous condition of the Institution, which has now become the accredited representative of the profession, and, after calling special attention to the clauses of the charter, proceeded to touch upon a great variety of subjects connected with the occupation and

ownership of land, and upon past and prospective legislation relating thereto.

I have always, said Mr. Ryde, been an ardent advocate for the extension of education; but I am bound to say that I approached the consideration of the question as applied to the admission of members to this Institution with much caution and reflection. That I did so is the more satisfactory to me now that I have formed a mature judgment that the course which the Council finally adopted, and which they have now to carry out under the charter, will be conducive of much good to the profession. The subject of education generally is a very extensive one; its consideration and development have become very popular and almost universal, and no profession can safely refuse to give it attention. As showing to some extent the direction in which general opinion is running in connection with this subject, I may mention that the International Committee of the Surveyors of Europe, sitting as a congress in Paris, in 1879, discussed, among other questions, the desirability of requesting the respective Governments of the several countries represented at that congress, to institute by compulsory enactment, that every surveyor should take out a diploma, after the manner of the surgeons and apothecaries of England, previous to being permitted to practise. But the English deputation to this congress was of opinion that its own legislature would not be likely to interfere in favour of a profession, at the instance of such profession, without some special demand on the part of the public. They further urged that, after all, too much importance must not be attached to the possession of such a diploma, inasmuch as the real qualifications of a surveyor could only be acquired after years of experience, coupled with integrity, perseverance, and intelligence. Hence, it constantly happened that surveyors of large experience were taken from one part of England to another on account of the special qualifications which they possess—a distinction which the possession of a diploma acquired in early life could not command. In no professions in England, except those of law and medicine, was any compulsory examination required, except as before mentioned. This was to be accounted for or explained in the case of medicine by the fact that the consequences of incompetency might involve questions of life and death; and the same might be said with respect to the legal profession in connection with criminal law. It would also be observed that the same rule applied in the special cases of surveyors appointed under the London Building Act, where infringements of the law relating to the construction of buildings might lead to fatal consequences. In the case of other professions, incompetency generally merely resulted in pecuniary loss, which, it was assumed, might have been guarded against by a careful selection. But the English deputation was, nevertheless, prepared to vote in favour of a diploma, which they could understand was probably more needed in France than in England, owing to the compulsory subdivision of property at the death of the owner, and the consequent necessity for a numerous class of surveyors of ascertained skill, whose services should be within reach of everybody. I cannot do better than refer to the very excellent speech made by our much-respected first Associate of Council, Mr. J. H. Lloyd, at the first meeting of the Institution of Surveyors, which speech will be found reported in Vol. I. of our *Transactions*, at page 14. I cannot describe to you the advantages of our Institution in words so happily put together as those which were then used by Mr. Lloyd, and all I can say is that any member of the Institution who has not read that speech would, I think, find pleasure in doing so. Taking that speech as my model, and pointing to the Charter which we have obtained as the result of the labours of the Institution down to the present time, I think I may fairly assume that the effect of the Charter has been to transform our Institution from a private society into a public body, having a fixed and well-settled constitution, with by-laws which cannot be altered without the previous approval of the Privy Council. Although it is not made compulsory, for a period defined in the charter, for a surveyor to pass an examination prior to his election as a Professional Associate, it is open to the Council to frame rules so as to enable him to submit himself for examination at once; and in the same way the

admission of Fellows may be facilitated. It is satisfactory to find that a considerable number of young men are availing themselves of the educational clauses of the Charter. Many have already joined the Student class, and many others are preparing to do so. They see the advantages which a certificate so obtained will give them over others who do not possess it, and the use which it will be to them in establishing themselves in life, whether they look to get appointments or clerkships in the offices of others, or start in practice on their own account. To employers, moreover, the advantage of the certificate will be most useful as a distinguishing mark between those who have been brought up to the profession and those who have not. If I am asked what I consider to be the best course of education for a surveyor, I may reply that I consider any of the subjects which are contained in the educational course of the Institution desirable; but it is impossible for any one man to qualify himself for practice in every branch of the profession. A surveyor and land-agent should have a thoroughly practical knowledge of agriculture, including a knowledge of agricultural chemistry and geology; he should also make himself a good accountant and bookkeeper. He should possess a knowledge of measuring land and making maps, a knowledge of timber and the art of measuring it, and above all things he should acquire, in as practical a manner as possible, a knowledge of the best systems of managing estates. The recent depression in agriculture, and the troubles which have befallen the landed interest generally in recent times, have rendered this last qualification more important than ever. However much the practice of agriculture may have been retarded, recent difficulties have shown more than ever the necessity for the services of skilled land-agents. It has been very much the custom during the last quarter of a century to assume that estates can be managed by gentlemen who have not had suitable previous training. It seems to me that that state of things must now be brought to an end. A land-agent responsible for the management of a large property must be able to determine by his own experience the exact amount of rent which a farmer can afford to pay under every circumstance which can arise. Moreover, the complaints of a tenant must, on the one hand, have proper attention, and, where necessary, must be met by relief or remedial measures; on the other hand, if every complaint of a tenant is to result in a reduction of rent, or some other advantage to the tenant, and disadvantage to the landlord, it will soon be found that there will be universal complaints, and that the landlord's interests will suffer. Again, an agent must be able to discriminate between a beneficial expenditure of capital and one which is not beneficial. On some estates it may be very advantageous to expend large sums of money in rebuilding farm buildings; on others it may be a great waste of money; as, for example, in the case of land near London or any other great centre of population, which, after a few years from the present time, will become building land. If a surveyor has intended to devote himself more particularly to the business of a building-surveyor, or, in provincial towns, to that of an architect and surveyor, he will, of course, turn his attention more particularly to the valuation of buildings and building lands than to agriculture and the management of country estates. Some knowledge of architecture, however, will be useful to a surveyor in any branch of practice; but I am now assuming that my address is made to surveyors, and that architects, strictly speaking, are without the limits of our Institution.

Referring to the Irish Land Act, Mr. Ryde said: The effect of the Act upon land subject to leases has yet to be ascertained; but it seems very impolitic to disturb a written contract. Take, as an illustration, the land in New Oxford-street. When that street was made, the land was let to builders who erected upon it the houses which now stand there. Those builders took building leases, and agreed to pay fixed ground-rents. The street was not a success; the houses when built would not let at remunerative rents, and eventually I believe it became necessary, in order to get them tenanted, to accept a rent for the house and land in some cases not in excess of, and in others only a little in excess of, the

ground-rents. In that case the lessees lost nearly the whole of the money which they had spent upon the houses, yet it would have been a monstrous thing to say that on that account they should be relieved from their contracts, and that the owners of the land should bear all the loss. It often happens that houses built under exactly similar circumstances turn out to be of great value, and very large profits are made by the builders who erect them; but nobody would dream, in those cases, of saying that the builders should give up the profit to the owners of the land.

THE LIVERPOOL ENGINEERING SOCIETY.

THIS Society, comparatively young, having been started in 1875 by a few pupils of Mr. Geo. Fosbery Lyster, Engineer-in-chief to the Mersey Docks and Harbour Board, has just brought out their first volume of Transactions. The volume before us contains nearly 300 pp. of closely-printed matter, and several plates of illustrations. Many of the papers are abridged, or only briefly noticed. The first paper is by the editor, Mr. Wilfrid S. Boulton, Assoc. M.Inst.C.E., and describes the closing of the river entrance of the low-water basin at Birkenhead, and its conversion into a wet dock. The walls built were intended to be of stone, but Mr. Lyster, the engineer, decided to use Portland cement concrete blocks, and the result is stated to be highly satisfactory. The walls form one hard, homogeneous mass, though the foundations are of "slurry." The paper is illustrated by sections of the wall, and the box for making the face blocks. The author furnishes detailed particulars of the staging, sheet-piling, excavation, the bearing piles, the method of making the concrete, &c., and tables of the proportions of the materials used in the backing and face blocks. These were 6ft. by 6ft. by 3ft., and the face blocks were made of eight to one hard stone concrete, and the author recommends the use of concrete in bulk, as better and more economical than blocks. Another paper by Mr. Anthony G. Lyster on the system of sluices at the New North Works, Canada Basin, Liverpool, is instructive, and Mr. C. Graham Smith's contribution on the landing stage and piers, at Birkenhead, shows the value of the water-jet system in driving piles. Among the longer papers we find a useful one by "Wrought Iron Girder Work," by the same author, an abstract of which we gave in our vol. for 1877; the "Status and Prospects of Engineers;" some valuable "Notes on Portland Cement Concrete," by Mr. Wilfrid S. Boulton; a paper on "Transatlantic Lines and Steamships," by Mr. Arthur J. Maginnis, M.I.N.A.; the "Permanent Way of Railways," by Mr. Alex. Ross; "Town Sewage and Refuse" by Mr. John S. Brodie; the "Design and Construction of Sewers," by Mr. C. Graham Smith; "Storing Water," by Mr. T. Duncanson; the "Use of Cast Iron in Engineering Structures," by Mr. John S. Brodie, M.I.C.E.; "Notes on Sewers and Sewage," by Mr. Edward H. Allies; "Railway Junctions, Gradients, and Curves," by Mr. Alex. Ross; "House Drainage," by Mr. E. H. Allies. The shorter notices give the gist of the papers, and the conclusions of the authors. A fully illustrated paper on "Hydraulic Machinery," by Mr. Alex. Ross, will be found of interest, and Mr. R. F. Pitt advocates piece-work as enabling men to make higher wages than by day-work. Mr. Allies's contributions on sewers and house drainage, and Mr. O. G. Pilkington's paper on "Sewage" treat pretty exhaustively on this branch of engineering. The abridgment of many of the papers increases, we think, the value of the volume as a permanent record of progress. Lecturers and readers are often inclined to be tediously prolix, and these contributions become more valuable for reference when they are divested of the superfluous words necessary to a spoken address. The volume has been carefully edited by Mr. Wilfrid S. Boulton, and forms a convenient octavo. It is published by the Society, Royal Institution, Colquitt-street, Liverpool.

BETON IN REPAIRS OF MASONRY.

THIS is the title of a paper read by Mr. O. Chanute, vice-president of the American Society of Civil Engineers, at the 13th annual

convention of the Society. The author gives an account of the uses to which beton has been applied on the Erie Railway within the last few years. Beton, as our readers know, is an hydraulic cement mixed with sand and a small quantity of water. The first instance mentioned of the use of beton on this railroad is in connection with the restored piers of the Portage viaduct over the Genesee River, a structure 850ft. long, 23ft. high above stream. The wooden viaduct was burnt down in 1875, and the stone piers were found to be much injured by the fire. These were from 10ft. to 30ft. high. To save expense it was determined to encase those piers exposed to the wash of the river, and the contract was made with Dr. Goodridge, president of the New York Stone Contracting Co., for that purpose. The piers were encased with 21in. of beton, as were also the ice-breakers at the ends. A coat of beton 2in. thick was laid on the piers to protect them from infiltration. A saving of 34,000 dols. was effected by the contract, according to the amounts given, the cost of the work having been about 6,000 dols., while the cost for rebuilding the piers in stone is estimated at 40,000 dols. Mr. Chanute says, the result has been very satisfactory, as the piers have withstood the strains of a lofty superstructure of iron which has replaced the old timber trestle framed piers carrying the railroad.

The paper further describes the renewal with this material of various stone culverts, abutments, and piers on the same line which have suffered by the elements. The Warsaw Culvert, on the Buffalo division, threatened, from frost and other causes, to fall into ruins. It was 146ft. long, 14ft. clear in opening, and was below an embankment 60ft. in height. The stones were crumbling or entirely decayed away in parts. To have dug it out and rebuilt it, would have cost 36,000 dols. A new facing of beton was put on for 2,200 dols., and the method adopted is simple. Centres were placed within the arch with plank lagging, a section at a time, leaving a space of 4in. between the planks and face of arch, and beton was then rammed by hand to fill up the cavity and crevices. The beton lining was continued down the walls to the rock foundation, and after this the centres were removed and the next section was treated in the same manner. The following spring the culvert was examined to see if water had percolated between the old arch and the lining; but no damage was discovered, and the lining has withstood the severest winter. The Clifton Culvert was similarly treated. It had been originally built of red sandstone, but had peeled, and was in a very dislocated condition; a 4in. ring of beton was rammed into all crevices and joints inside, and beton buttresses were built at the ends. In 1877 the Bergen tunnel at Jersey City, driven through trap rock, was found full of seams and faults; the brick arching of some portions had peeled off and become disintegrated by alternate freezing and thawing, and it was decided to arch over a section 139ft. long where the rock was shattered, and to relime with a thin coating of beton another section 30ft. long, in which the bricks had been most injured. Iron centres and wooden lagging were erected, and the beton rammed in the space and crevices as before. The work was done at night, not to interfere with the trains. In order to drain the infiltration, drain-tubes were left in the beton by inserting hollow blocks. The work has stood well. These successes led to the repair of a number of culverts on the Buffalo division which had got into a bad state, like the one at Warsaw. These varied in length from 147ft. to 46ft., and were of spans varying from 10ft. to 6ft. The bench walls were broken-backed, the arches distorted, and the parapet walls were thrust out. The engravings given show linings of beton, buttresses of the material in one case at the ends, new inverts and foundations. These were all erected or repaired with beton, on John C. Goodridge's patent. Another instance of encasing piers is recorded, at the West Paterson Bridge over the Passaic River. The piers were erected upon cribs on a sandy bottom, and these had shown signs of settlement, and shaking by the trains. They were enveloped in a shell of beton, from 4in. to 12in. thick. Wooden frames were placed, planked inside, round the piers, allowing the requisite space, and this was rammed full of beton.

The author has full confidence of the result. The beton is capable of standing a tensile strain of 300lb. per square inch, which is greater than

the stress in the pier would demand. The paper enters into particulars of further repairs contemplated at Portage, and the idea of putting an apron or floor of beton over the bed of the Genessee river, which has been worn away by the disintegration of the clay shales, caused by the scour. By this means it is hoped the excavating action of the water near the piers of the bridge will be averted. Alluding to cost, which has varied according to the difficulties experienced, the author states, it has been from 60 cents. to 1.00 dols. per foot cube, or from 16.20 to 27 dols. per cube yard. No formula is given of the composition of the beton. A Portland cement made at Boulogne, in France, has been used in all the works, and American cements have failed. The author justly concludes that beton might be more largely employed for the repair of structures, the rebuilding of which would entail expense or interruption of traffic, at a cost of 10 to 20 per cent. that of new work.

PRACTICAL NOTES ON PLUMBING.—XX.*

By P. J. DAVIES, H.M.A.S.P., &c.

INSIDE WORK, OR SANITARY PLUMBING.—FIXING CLOSET-TRAPS.

BEFORE fixing the trap for a water-closet apparatus it is advisable to use. For a valve-closet the distance from the wall A, Fig. 125,

F I C. 125.

to the centre of the trap-dip should be 14in. Speaking generally, closets are very narrow, frequently not more than 3ft. wide—5ft. is considered a barn of a closet. When the closet is from 3ft. to 4ft. wide, the trap should be fixed 1in. out of the centre to the right, as shown at 17, or between B and E. This is to allow the handle and dish of the closet to come within the flap of the closet seat. This also applies to pan-closets; but for the pan-closet the distance from the back wall, A, to the centre of the dip should be only from 12½in. to 13in.

For Jennings' Closet, and some other special makers, you will find it necessary to examine the outgoes and trunks, and so ascertain the proper distances. In a future chapter, I will give the exact distances for those most in the market.

Fig. 125 plainly illustrates the method of trimming the joist for the trap. The trimmer, G, carries the joist, H I J. One end of this trimmer, in this case, has a bearing upon the brick wall at L, the other end is trimmed into the joist, K. The trap is supported upon two bearers, M N; and as can be seen, the ends of these bearers rest upon the brickwork, the other ends are trimmed into the trimmer, or are sometimes made to rest on a fillet, as shown at A A, P P. Q and R are two bearers to support the boarding for the floor and closet-seat to rest upon, &c. This trimming is the general method adopted throughout England, and should be well noticed and remembered by all carpenters. The trimmer should always be kept far enough back—say 2ft.—from the back wall, as shown at F.

* All rights reserved.

TWIN CLOSETS.

London builders are certainly very much to blame for not, when building houses, providing proper children's closets. I have fitted the whole of the closet and plumbing work for some scores of builders, many of whom were and are in a large way of business, and only one man has consented to have children's closets fixed; and furthermore, to show how much this branch of the trade is neglected, I only know one out of the many dozens of closet-makers

plenty for the bottom of the safe to stand away from the wall, because the top can easily be bent over against the riser, if required.

The safe should be properly soldered down to the dip of the trap, and *sunk* as at A B, Fig. 128, in order to allow the solder to be wiped level or flat with the bottom of the safe.

The angles of the safe may be soldered, bossed, or dog-ear'd up; the last-named will not have as neat an appearance as when bossed, but if properly done will answer every purpose.

F I C. 126

who make a valve-closet for juveniles—viz., Warner and Sons, brassfounders, The Crescent, Cripplegate, London, a drawing of whose trap I shall furnish later on. Fig. 126 illustrates by plan the method of fixing the traps for twin-closets, and also the trimming of joists, &c. In closets having plenty of room, the traps may be fixed at equal distances from the side walls, E B; but where the closet is narrow, the small closet should be on the left-hand side and nearer to the wall; then the large closet-trap may be fixed the same distance from the back of the brickwork, as from E to A. The traps are trimmed in much about the same manner as in Fig. 125, excepting the end of the bearer, P, Fig. 126, which I have shown run into the brickwork, and is now in the way of fixing other pipes up the chase, but which may be supported by another shallow trimmer, Q, so fixed that it does not come in the way of the under-side of the soil-pipe, &c.

The elevation of the plan, Fig. 125, is shown at Fig. 127. S, the soil-pipe; (1) the out-go

Workmen who choose to dog-ear the corners must be careful not to beat the lead too close together, as, although the work may look neater,

it must be remembered that substantiality is essential, and the close beating will destroy the angles.

CHIPS.

The fifteenth annual convention of the American Institute of Architects is being held at Washington this week, beginning on Wednesday last. Particulars of the papers to be read and subjects to be discussed have not yet reached us.

The construction of the Maidstone and Ashford extension of the London, Chatham, and Dover Railway will be commenced within the next fortnight at the Maidstone end. Mr. Hopkins is the engineer, and the contract has been taken by Messrs. Lucas and Aird.

A cabman's shelter was opened at Chesterfield last week. Mr. Hanby, of Hagland, was the builder.

About two and a half years since the town council of Brighton, in pursuance of the North-street improvement scheme, demolished a block of buildings which had previously screened the Chapel Royal, and thus exposed to view from North-street a façade which was never intended to be seen, and has been regarded by the townspeople as an eyesore. Two designs for decorating the blank surface were proposed, and met with no public favour, but eventually a design for a new façade in red brick and a clock-tower, made by Mr. Arthur W. Blomfield, M.A., was approved. Both tower and wall have been carried up to the old parapet level, but the works will be stopped at the end of this week unless further funds are subscribed, some £400 being needed to complete the undertaking.

At the Carlisle Consistory Court on Wednesday week, plans by Mr. John Cory, of Carlisle, were approved, and a faculty decreed for alterations to Holy Trinity Church, Carlisle, including reseating and re-flooring, and providing new pulpit, reading-stools, litany desk, choristers' stalls, font, and heating apparatus, and enlarging the vestry, the cost being estimated at £750.

The additional buildings just added to St. Edward's Orphanage, West Malvern, were opened on Thursday week. They include a schoolroom, accommodating 120 boys, and classroom, and over these a dormitory for 80 boys. Mr. F. W. Hunt, of London, was the architect, and Mr. Smith, of West Malvern, the builder.

of the trap to the soil-pipe; (2) the trap. By the side of the soil-pipe are fixed the smaller pipes, that can only be seen at the top near M and C. This also illustrates the lead-safe of the closet and overflow. The overflow should not go into the soil-pipe unless under very especial circumstances, and then great care must be taken to insure the trapping being thoroughly perfect. The safe should be large enough to admit the closet, but not so far in front that it will come in the way of the closet-seat riser. It should never project beyond the front of the basin, which is generally 23in. from the back wall, so that 22in. will be

OUR LITHOGRAPHIC ILLUSTRATIONS.

COMBINED POST AND TELEGRAPH OFFICE, MADRAS.

THE new combined post and telegraph office, Madras, covers a considerable area of ground. It is 352ft. long, and 162ft. broad, open on the east, south, and north sides. With the exception of the central hall, the building is in three stories. The ground-floor, devoted to servants, stores, kitchens, &c.; the first floor to office accommodation; and the third floor, over the wings, to residences. The only building materials available in Madras are a hard gneiss and red brick with terra-cotta. As neither the red brick nor the gneiss are good in colour, all architectural effect, when plaster is discarded, must be obtained by the massing of the light and shadow, and the flicker of tracery. The horizontal bands will be in glazed terra-cotta of intricate pattern, but low in tone, so as not to kill the gneiss dressings. The style may be termed "Hindoo Saracenic" as regards details, and although adaptations of specimens widely separated geographically, great care has been taken to preserve artistic unity in the whole design. The high-pitched roofs and dormers are in the Travancorean palatial style; but below the eaves of the roof all work apparently of wood (and really of wood in the original style) has been changed to stone, as sanctioned in the very beautiful example at Benjapoor, which meets with universal admiration, and from the study of which the projecting eaves have been designed. The arches, columns, and all other details are in cut stone, in the Ahmedabad style of art. The lighter stonework forms a pleasing and legitimate link with the wooden dormers above. Few architects who have not actually practised it, can imagine the difficulty of dealing with deep loggias all round a building when circumstances compel the roof to be shown. The simple and general way of overcoming the difficulty, is to make the roof of the verandahs flat, and to pitch the main roof. The result is eminently suggestive of a Swiss chalet surrounded by a cage of Gothic, Classic, or whatever it may be; the style never appears to extend, and does not actually do so in many cases deeper into the buildings than the outer skin or cage. Solutions to other problems connected with building in India have been attempted, but these are not likely to interest the general reader. The estimated cost is about £100,000, exclusive of internal fittings.

THE RISE, SESSINGHILL.

THE villa shown in our illustration, now in course of erection, is one of several Mr. J.

Pether proposes carrying out on his building estates at Sunninghill and Bagshot, there being a good demand for this class of dwelling in the neighbourhood, owing to the well-known reputation of Ascot being one of the healthiest parts of England, as well as for its sporting associations. The house is being built of deep red bricks from Bracknell; the walls are hollow up to the line of the weather-tiling; the exterior face will be weather-pointed with ash mortar, a sparing use of terra-cotta and moulded brick being introduced for ornament. The plan was so arranged as to have the windows of the best rooms command the views of the Surrey Hills and surrounding country. The whole of the internal woodwork of principal apartments will be in pitch-pine, varnished. The stables and coach-house are to be erected at a lower level, to the left of the residence. Messrs. Byrne and Crombie, of 303, Strand, and Windsor, are the architects.

OLD HOUSES AT IPSWICH AND RYE.

THE illustration of the "Neptune Inn," at Ipswich, is from a drawing in brown ink, which was exhibited in the Royal Academy this year. Like several other old houses in Ipswich, it is an interesting subject to the student of English Domestic work. At the back of the house there is a room with a good oak dado, with linen panels well carved, and several other rooms in the house are worth a visit; the earwing has, however, been greatly defaced with paint and varnish. The inn, like the private house illustrated on Sept. 9 last, from Mr. Arthur Keen's drawing, is situated in Fore-street, St. Clement's. The houses at Rye are examples of a few of the remaining old picturesque gable houses left in that town. The subject is close to Mermaid-street and the old church.—Tues. J. B. HOLLAND.

ST. MARK'S CHURCH, FARNBOROUGH.

THIS church is intended for the population brought together by the Aldershot North Camp. The foundation-stone was laid by the Duchess of Connaught on the 26th July, 1880, and the first portion, consisting of nave, chancel, and narthex, was consecrated on the 27th September, 1881. The church, when completed, will seat 583, at a cost of about £5,000. The architect is Mr. J. E. K. Cutts, of London, and the builders Messrs. Martin, Wells, and Co., of Aldershot.

STEAM LAUNDRY, BATTERSEA PARK.

THE works of the London and Provincial Steam Laundry Company, situate in the Battersea Park-road, about half-way between the Battersea and Queen's-road stations on the London and South-Western Railway, are the largest of the kind ever yet opened. They cover a space of upwards of an acre and a-half of ground, afford employment to 20 male and 150 female operatives, of whom 32 are provided with lodgings on the premises, and are capable, when working up to their full power, of dealing with from eighty to ninety thousand "pieces" of various descriptions per week. The buildings are from the designs of Mr. Ernest Turner, architect, of 246, Regent-street. The contractors for the building are Messrs. Scrivener and Co., of Fitzroy-road, N.W.

CHIPS.

THE new sea-wall at Seaford, Sussex, was completed on Saturday, and on Monday evening Mr. J. Swanwick Lee entertained the workmen engaged on the work at supper, when the contractor, Mr. J. S. Seel, presented the only man who had been engaged on the work throughout, William Russell, with a silver watch. The engineers of the undertaking, by which a large tract of land will be retained and protected, are Messrs. P. S. Lee and W. Webb Turner.

THE retiring Mayor of Kidderminster has announced his intention to present new gates and palisades to the parish church, to be manufactured by Messrs. Hill and Smith, of Brierley-hill; at the same time the bells are to be rehung and a set of chimps provided.

A new cemetery is about to be formed at Stoke-next-Guildford upon a site 8 acres in extent, adjoining the South Western Railway. It will be laid out, and the buildings will be erected from plans and designs of Messrs. Peak, Lunn, and Peak, architects and surveyors, of Guildford.

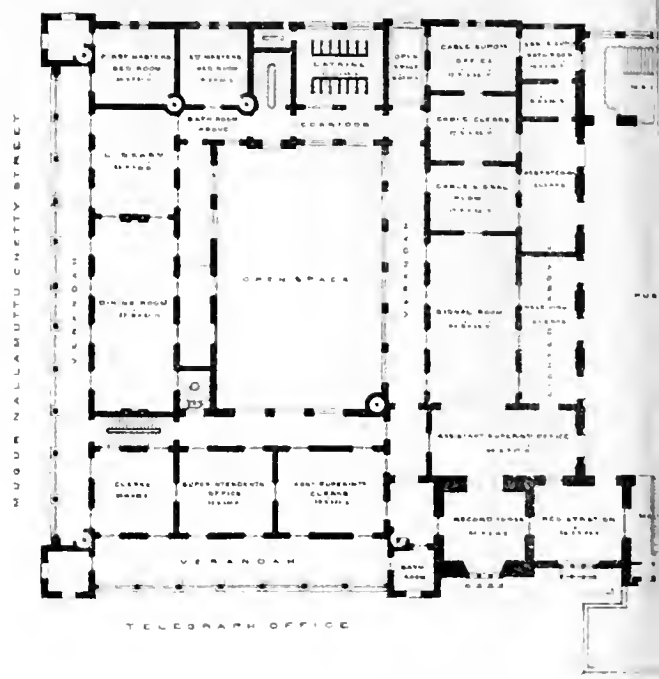

SMOKE ABATEMENT.

IN opening, on Wednesday evening, the 128th session of the Society of Arts, Sir Frederick J. Bramwell, F.R.S., M.Inst.C.E., referred at considerable length to the scientific problems of the day, and amongst these to that of the abatement of the smoke nuisance. This was a question which must increase in importance and in interest with the growth of our large towns. In London there are, he remarked, four millions of persons spread over an area (that governed by the Metropolitan Board of Works) 117 square miles in extent, involving, therefore, even if the 117 square miles were in the form of a regular circle, a diameter of 12½ miles, or a radius of 6½ miles. Under these conditions, one sees how extremely difficult it is for the inhabitant of the centre of such an area to have a clear atmosphere. Whichever way the wind blows, he must receive the products of combustion of 6½ miles of a more or less densely populated district, and probably of certain manufactures. As regards manufactures, however, the Smoke Act in London works so well that a very little of the nuisance arising from smoke is due to the chimneys of manufactories. It is a common observation that if a manufacturer emits smoke from his engine chimney, he must be losing a large quantity of fuel in an unconsumed condition, and that he is not only annoying his neighbour, but is at the same time injuring himself. The fact, however, is that the weight of the solid particles of the smoke is almost inappreciable as compared with the weight of the fuel burnt—only a fraction of 1 per cent. The means employed to prevent smoke from engine-boiler fires are, it may be said, almost universally a very free admission of air above the fuel. In this manner, if there be heat enough in the furnace, it is easy to insure the combustion of smoke, but it is by no means certain that this combustion will not be effected at the risk of passing through the fire and through the flues a far greater weight of air than that really needed to properly consume the combustible materials, and that in this way a loss of heat may readily occur, greater than that which would arise from the sending a few pounds per ton of coal burnt, of unconsumed particles of carbon, into the air in the form of smoke. If these facts were always present to the speakers and writers on the smoke question, we should not have such repetitions of the statement of "the folly in a pecuniary point of view of those who do not voluntarily burn their smoke." With respect to domestic fires, admitting that close stoves properly constructed were more likely to consume the smoke than open firegrates, and also that with them less fuel was needed to heat an apartment, he observed that where there is an open fireplace there is of necessity ventilation. The natural man, he continued, especially if he is a poor one, sparingly fed, insufficiently clothed, objects to ventilation, because he fears draughts. Give him an open fireplace and he must have as much ventilation as will allow the smoke to go up the chimney. I look upon our open fireplaces, wasteful as they are of coal and productive of smoke, as great sanitary agents in dwellings, especially of the poorer classes; and I will appeal to any one who has had experience of the atmosphere of Continental rooms in the winter time, when the windows are closed and a close stove is employed, as to whether such an atmosphere is not far worse than that which prevails in rooms where open firegrates are used; and I think I may without fear of the nature of the answer ask whether, on the whole, the appearance of the inhabitants of London, smoky as their atmosphere may be, does not compare favourably with that of those who live in cities with a far clearer atmosphere, but in rooms where, owing to the use of close stoves, there is no efficient ventilation? These considerations alone should make us pause before we determine, for the sake of clearing the atmosphere, on giving up open fireplaces, and on resorting to stoves having good combustion. But there is another consideration, which I think should not be lost sight of, and that is the cheerfulness and companionship of an open fire—advantages which, I think, few Englishmen would willingly give up. Nevertheless, if those who turn their attention to the subject will bear in mind this fundamental question of proper ventilation, and take care that it is not tampered with, all of us would rejoice to see an improvement in the clearness of the London atmosphere.

THE APPRENTICE QUESTION.*

I HAVE been induced to write the following pages from a feeling that the subject is one which is of importance both to employer and employed. I know that it is a thing to which the latter are somewhat opposed; but I am hopeful that, at all events, I may convince some among the more sensible of them, for whose opinion I entertain respect. The subject I propose to discuss is that of apprenticeship. It will, I am sure, be conceded by both master and man, that a mechanic cannot be an efficient workman unless he has been taught; and in my opinion the best way of teaching is by means of the old-fashioned plan of apprenticeship. At one of the interviews with the workmen in 1872 I broached this matter, and, I must confess I was greatly surprised to find that the delegates were so unanimously opposed to it. I was the more surprised because these men were shrewd, and some of them even had been apprenticed to their trades. I have made inquiries among the men as to their objections to the apprenticeship system, but have never yet heard any good grounds for such objections. There seems to be an indefinable dread of a something, an objection resting on no apparent basis. I cannot understand what can be the feelings of a really efficient workman who thoroughly understands his trade, when working next bench or banker to a man who knows next to nothing, and who has frequently to ask for assistance when setting out his work. This is, unfortunately, too often the case, because too many of the men now in the trades have not been properly trained. Can this efficient workman be satisfied when he goes to the pay-table, and receives the same wage as the "duffer"? I am afraid the real reason is that the "duffers" are the majority, and, therefore, carry things with the high hand in their lodges, and the respectable efficient man is nowhere, and has to grin and bear his chagrin. Some societies restrict the number of apprentices. No doubt such a rule may be necessary, as there may be unscrupulous masters, but I take it that but very few would find too many apprentices a paying business. In fact, I do not believe that the work performed by apprentices ever pays; but as a master owes something to the trade and his fellow-men, it is not too much to ask him to make a temporary sacrifice, especially as in the long-run, he or his successor will derive some benefit by reason of better and more efficient workmen. I have heard it argued that seven years is too long a time for youths to serve; but on mature consideration I am of opinion that very few trades can be thoroughly learnt even in that time. Owing to the great demand of late years for labour, it has become difficult to discriminate between good and bad men, and a foreman is often sadly puzzled to set the work to the men according to their capabilities. Through this great demand for men to carry out large building operations throughout the country, many young men begin their career at what is called "field ranging," that is, on the houses built by speculating builders. These youths get a smattering of knowledge of their trade, and as soon as they themselves consider they know enough, come to work for the large builder and contractor, and owing to this want of discrimination they get lost in the crowd, and pass as good men. From information which I have been able to gain as to the customs prevailing in other countries, I find that in Sweden apprenticeship and enrolment in a guild were compulsory, but as the most advanced principles of Free Trade were adopted, these customs were abolished, to the great disadvantage of the community, and now there is a strong feeling that the old custom should be revived. In Holland, which is more conservative, the custom still exists. In France, boys are apprenticed, but for a shorter term than ours, but better opportunities are afforded by the establishment of technical schools, where a youth can gain instruction in the higher branches of his trade, and in one which is most important, and which is quite overlooked by us—viz., the nature and the character of the material he is using. The ignorance of some of our workmen is truly lamentable. For instance, one sees frequently a painter thinning varnish with turps, thus mixing two liquids of totally different characters;

and again, a plasterer gauging Portland cement and plaster together, one a slow-setting material, and the other a quick one, thus neutralising or destroying the effects of both. The French go so far as to apprentice coachmen, for I noticed lately in Paris a char-à-banc full of men, who were receiving not only instruction in driving, but in what is most useful, their nearest way about the city. In Germany, bricklayers are not apprenticed, but joiners, masons, and painters are, but usually for only two or three years. The guardians or parents pay from £10 to £20 premium, and for that sum the master keeps the boy in board and lodging, but does not give any wages. At the end of the term the lad generally stays on, and receives a small wage. Most of us know something of German workmen, and must have noticed that they are very conscientious in their work, and appear to take great pains—their heart seems to be in it. One reason for this is, that men in Germany are paid only according to merit, except in North Germany, where Social Democracy is rampant, where they are trying to emulate our splendid principle of paying all—good, bad, and indifferent—alike. The system of technical education is also carried out, if anything, to a greater extent than in France. Looking, further from home, I read that the Japanese have taken the question in hand. "The Chamber of Commerce of Tokio, in its sitting of the 6th of December last, was occupied for a long time with the question of contracts between masters and apprentices. It unanimously decided that a petition should be addressed to the Government, praying it to fix by law the number of years that the apprentice should give to his master, in order that the latter, sure of the time for which he could count upon the services of his pupils, might have an interest in giving them a complete instruction in his calling. Though before the restoration of 1868, it seems that there were no precise rules upon the matter, engagements were, nevertheless, made by private contract, which so effectively bound the apprentice to his master for a stated period, that practically it never happened that the pupil left the master, from whom he received lessons and advice, before the end of his apprenticeship. To this wise measure is attributed the progress of the country in many arts and industries. But since this custom has by degrees fallen into desuetude, the apprentice, who may find the smallest pecuniary advantage by leaving his master, fails not to do so on the morrow; and the latter, in the face of such versatility on the part of his pupils, protects himself by forgetting to divulge the more important secrets of his art. Hence arises the scarcity of good workmen, and the general decadence of their arts and trades. The embroideries upon silk stuffs (Kin-ran), which at one period made the 'glory and the fortune' of the country, have become very rare, and are now almost priceless; not so much in consequence of the costliness of the required material as the difficulty experienced in obtaining skilled embroiderers. The Chamber of Commerce, with a view of remedying this evil, and still more to create a constant progress in their industrial arts, has recognised the necessity of fixing an apprenticeship which shall bind the pupil to the master for a certain number of years, to be determined according to the nature of the art or trade which the apprentice shall undertake." I have mentioned the foreman. The foreman is a factor in the matter who requires great consideration. I may say he is the most important factor; for however willing a boy may be to learn, and however anxious the master may be for him to get on, without the goodwill and assistance of the foreman, it is impossible. I would suggest, that if the master receives a premium with the boy, he should allow the foreman to participate. This would induce him to take an interest in the lad. Some employers allow their foreman to take apprentices; this is not in my opinion a good plan for the master, because virtually he is not master; nor for the boy, because the foreman is not always in constant employment, and if he receives a profit on his wages, it is a system, to my mind, which is most objectionable. I believe that the good men would gladly hail any means that could be devised for improving the state of their trades, were they allowed freedom of action and opinion. But this they know they cannot expect, as long as the majority is composed of those who, knowing their own imperfections,

aim at keeping wages and time at one dead level, for good and bad alike. This has been the action of the trade unionists, and I fear will be so until the trades are improved. The only way that I see to attain this great object, is to teach youths in a proper and systematic manner, viz.,—by apprenticeship for a term of years. By securing the boy for a term of years, you get over the difficulty which I have already named, of their running off when they are vain enough to think they know their trade. This is a difficulty which always has, and I suppose always will exist. The improvement of our workmen has, I am aware, occupied the attention of many who have their welfare at heart, and it is only by improvement that we shall be enabled to keep our place among the other nations in the markets. We have heard much of technical education. My own idea is that we want to begin at the foundation, by properly training workmen, who belong to those trades which are mainly carried on by manual labour. Of course, I refer more particularly to the trade to which I belong, viz.,—that of building; but these remarks apply equally to other trade. Feeling very strongly the importance of the subject of apprenticeship, I have for many years advocated it among those with whom I have been thrown. Feeling also that the scheme proposed by the large City companies must take some years to develop, and that the smaller companies could not be expected to do much towards that scheme, and I must confess not having much confidence that technical education would be the right means of improving the lower class of trades (if I may use such a term as "lower" for those which are purely manual), I suggested to the Guild, of which I have the honour to be a member of the Court, to devote some of their income to educating lads in their trade. To this end, the Worshipful Company of Tylers and Bricklayers, after very careful and anxious consideration, determined to give premiums of £25 each to masters who would take boys for a term of years. The court has annually apprenticed three boys, two out of their own funds, and one through the liberality of one of their members, with the most satisfactory results. I have brought the matter before other guilds, and now hope that they may see their way to follow such a good and useful example. The National Association of Builders of Great Britain have recently taken up the matter, and in a circular issued to the trade, the late respected president very rightly points out the necessity of introducing a superior class of boys and youths, and recommends employers to apply to the teachers of schools, for boys fit to be apprenticed. No doubt the improvement in the education of our poorer brethren has had much to do with deterring boys from learning manual trades. They prefer to go into offices; but now that all boys will be better educated, and there can only be room for a limited number in offices, a proper level will be found, and it will be considered no degradation for an educated boy to work with his hands. I regret to say that there are many employers who refuse to take apprentices, not caring for the bother or for the first loss. This, to say the least of it, is a selfish feeling, for these people ought not to expect to have men ready to their hand, trained by others. It is also a short-sighted policy, because the supply of good men must, on account of the great demand, be limited, and employers are daily paying full wages to inferior men. This, perhaps, they do not think of. On the other hand, there are many employers I know, who, declining to take apprentices, allow the sons of their foreman and old hands to learn their trade in the shop. This, of course, answers the same purpose. The difficulty of getting a good class of foreman, free from the influence of trade union, would by means of apprenticeships be materially reduced, as an employer would have a better chance of training and bringing forward under his own eye, boys who in time would take that responsible position. In concluding these remarks I would add that, in my opinion, the wage question is very important. Formerly nearly all apprentices lived with their masters, now it is rarely so; therefore, the boy should receive such a wage as will keep him, or nearly so. The Tylers' and Bricklayers' Company stipulate that during the first three years an apprentice receives very low wages, but that

* A paper read by the president, Mr. STANLEY G. BIRD, at the last half-yearly meeting of the National Association of Master Builders of Great Britain.

when he begins to know something of his trade, and ought to be useful, he shall then receive such a weekly sum as shall be an inducement to him to exert himself, and that in the last year he shall receive about one-third less than the full current wage paid to workmen. This is the due of the young man, who at twenty-one is naturally full of pride, and is, or ought to be, capable of doing a good day's work, and who would feel galled at receiving a small nominal wage of, say 18s., while the next man, who perhaps is not so good, receives nearly £2. He loses heart in his work, and he also loses self-respect. Again, perhaps, just when he is useful, if he has not the inducement of good wages, he thinks himself better than he really is, and, travelling being cheap, takes himself off to some distant town, and there gets full money. I have said that nowadays boys do not, as a rule, live with their masters; but I do not mean to say that the responsibility of a master ends day by day when the lad leaves his work; I think that he should endeavour to induce the boy to devote his play-time to healthy and useful amusements, by encouraging him to attend during the winter time drawing-schools, which are now to be found very generally in most localities, also lectures, and mechanics' institutes. During the summer time let him try cricket and boating. All these give a good tone to the system, both morally and physically, and last, though not least, let him join a rifle corps; he will then begin to feel the importance of taking his place as a citizen; he will be taught habits of obedience, punctuality, neatness of dress, order, and method; he will be set up in person, and begin to feel some self-respect, besides having a good deal of priggish nonsense knocked out of him. As concerns the trade in which I am interested I do not think it is practicable, but in others I would suggest the holding of exhibitions of the works of apprentices. It would certainly show what they could do, and cause a very praiseworthy emulation. Prizes might be given, and in some cases the freedom of the companies bestowed as the highest reward, as is now done by the Turners' and Painters' Companies.

DR. ALLMAN ON ART AND ART SCHOOLS.

AT the first annual meeting of the Poole School of Art, held on Friday evening, Dr. J. G. Allman, F.R.S., Ex-President of the British Association, distributed the local prizes and the Government certificates gained by students in the newly-formed school, and afterwards delivered an address in which he said:—Our new school has for its object the cultivation of both art and science. This is a wise association. Art and science are united in an inseparable sisterhood, in which each lends her aid to the advancement of the other, and it is satisfactory to see that in both departments we have had so goodly a display of successful work. I shall confine myself to-night to art as the subject for a few words of counsel and encouragement. There are two aspects under which art, as taught in our schools, admits of being studied. It may, in the first place, be studied in its application to the manufacturing industries of the land, and in the second place in its higher aspect, viewed independently of all extrinsic relations, as the simple expression of natural beauty and truth. The former is known as design in the special sense of this word, and its value in a great manufacturing country like ours cannot be over-estimated. It is indeed becoming more and more evident that if in a large proportion of our manufactures we would hold our place amid the world-wide competition against which we have to contend, we must rely upon the principles on which the study of design is based. The advantage which in this respect Continental manufacturers enjoy over ours was long ago apparent, and the country becoming awakened to the danger of exclusion from the markets of the world, it was deemed advisable by Government to establish throughout the land, Schools of Design, where the application of art to various manufacturing industries might be taught. The success of these schools can no longer be questioned, and we may now compete in the artistic element of our manufactures with any country in the world. The effect of such studies

is twofold. They have enabled the manufacturers to originate forms of beauty and combinations of colour which are founded on inviolable principles, and therefore command the ready acceptance of mankind; and further, they act in improving the general taste—in intensifying the appreciation of beauty and the repugnance to all that is low and vulgar in form and colour. But art may be regarded in its higher aspects independently altogether of its applied relations. This is art in its noblest form; it is that which finds expression in the works of the great painters, sculptors, and architects. It has grown with the growth of manhood, and become developed with the development of the human mind. We shall perhaps be impressed still more profoundly with the dignity of art if we bear in mind that it may be regarded as a faculty essentially human. A capacity for art, even in its simplest manifestations, is one of those characters which, like articulate language, essentially distinguishes man from the lower animals. Most of the faculties which are regarded as characteristic of the human intellect may be found in a rudimentary condition in the lower animals. But the power of imitating form, by drawing or by modelling, is one of which no trace exists anywhere but in man. And yet among the very earliest indications of man's existence we find unmistakable evidence of such a power. This evidence carries us back to a period when European man was coeval with the now extinct mammoth and cave-bear and hippopotamus—a time when the reindeer, whose area is now confined to the precincts of the Arctic circle, must have roamed over the plains of southern Europe. It is found in rude drawings discovered in the caves of Perigord, in the south of France, along with rough flint implements, undoubtedly fashioned by the hand of man. Among these drawings is a portrait of the mammoth himself, engraved upon a piece of his tusk, and having the principal features of the living beast handed down to us with a rude but graphic fidelity, which testifies to the enormous antiquity of the delineative faculty in man. I, therefore, look upon this faculty and that of articulate language as the grand points of distinction—the essential differences by which the intelligence of man stands forth boldly and definitely separated from that of the very highest of the sentient beings by which we are surrounded. If art in its simplest and least developed form may thus be regarded as an exclusively human faculty, we may well expect it to advance with social progress and with human culture, until in its higher phases it becomes a refining and elevating power, intensifying all that is best and noblest in our nature, and in undying antagonism with all that is low and mean and vicious. The power exerted by art over the moral faculties of man must be mainly sought for in its tendency to bring us into intimate communion with nature, and under all the ennobling and purifying influences which flow from the fair and wonderful world which surrounds us. To give truthful expression to sources whence such influences spring is the aim and end of art. To attain this end long and careful study of form is essential. At the base of this lies a knowledge of drawing. Unless you can draw with accuracy and ease it is vain to think of excelling in any department of art. Our art-schools afford admirable opportunity of acquiring facility in drawing; but it needs industry and patience, and a determination to resist the temptation of passing to higher grades before you have obtained a complete mastery of this, the most important of all the conditions of success. For the truthful expression of nature there must be a careful delineation of specific form. There must be no evasive generalisation—no conventionalisms, which, however admissible, or even demanded, in the department of design, are utterly at variance with the requirements of those higher phases of art where the truth of nature is, above all things, paramount. We have this been recognised by our great landscape painters, who are always greatest when they depart least from the simple truth of the natural forms which surround us. Do not, however, mistake me; do not imagine that when I say that a truthful rendering of nature, even in detail, is the aim and end of art, I would counsel a servile attempt at mere imitation. The great landscape painter is the interpreter, not the mere imitator, of nature, for with all our efforts at imitation of

form and colour, how far, far short do we fall of the utterly inimitable original! Mere details of form and colour will in themselves never make a great picture. Years may be spent in an attempt to depict all the details of a piece of natural scenery; every curve in the outline of a cloud, every boulder on the hill-side, every spray in the ramification of a tree may, after infinite labour, find its place upon the canvas; and yet the result may be poor, and weak, and expressionless, with no power to awaken in us one high emotion, or satisfy a single longing after the true and beautiful in nature. Far different is it with him whose works are destined to endure and become a power throughout time. He knows that in the world which surrounds us there lies a deep meaning hidden from the uneducated eye, but which reveals itself to the painter, who, by long years of study, has made himself worthy of the gift, and which, no less than obvious form and colour, must find its expression in his picture. It is this faculty which makes the painter; and if any of you have decided on making painting the business of your lives, you must never rest until you have attained to it. But for this, there is no life of idleness before you; year after year must be spent in deep and earnest study, and in constant communion with nature. You must become familiar with her in all her moods; in sunshine and gloom, in storm and calm; in all her varying aspects, from the first green buds of the young year, when the raiment of early spring is cast over the forest, to

The last red leaf, the last of its clan,
That dances as well as dance it can,
Hanging so light, and hanging so high
On the topmost branch that looks up to the sky.

Then only will you be prepared for the high mission which awaits you, for the privilege of becoming the interpreter of nature to your fellow-men, of revealing to them the beautiful, the true, and the good of God's bright universe, and thereby making them wiser, and better, and happier.

THE PROPOSED NEW WAR OFFICE AND ADMIRALTY.

IT is proposed to concentrate the scattered departments of the War Office and the Admiralty in one homogeneous block of buildings. For the accomplishment of this design Parliamentary powers are to be sought in the coming Session.

The scheme which is now being prepared seems to bear the stamp of efficiency. In the first place, it brings the War Office into juxtaposition to the Horse Guards. The latter place is to remain where it is. But from the Horse Guards up towards Charing-cross, as far as Biddulph's Bank, a clean sweep is to be made. The building which serves as the office of the Paymaster General is to be cleared away. The edifice which affords a harbour of refuge to the Lords of the Admiralty is to be improved off the face of the earth. A group of four houses following next in order are likewise to be removed, thus creating a long line of frontage, which will be divided equally between the War Office and the Admiralty. But while the eastern front will be thus conspicuous, the block of buildings which it is proposed to erect will stand on a site opening up advantageously in other directions. The ground to be cleared includes not only that occupied by the line of buildings already described but also a large space at the rear, at present known as Spring-gardens, New-street, and Spring Gardens-terrace. Already the Admiralty Offices have extended so as to comprehend nearly all this region. When a Committee of the House of Commons reported on the subject four years ago it was stated that as many as twenty-eight of the adjacent houses were occupied by the Admiralty in addition to the main building. All this is to be altered, and by the concentration of the two great Departments of the Army and the Navy a range of buildings, forming part of one design, is to cover the area now broken up into ill-formed streets and scattered offices. One outlook will be towards the Parade appertaining to the Horse Guards, taking the line of the Admiralty garden wall, while the west front will follow the line of the present Spring Gardens-terrace, and what is now the western end of New-street. The private gardens in front of

the terrace are to be thrown open to the public as a sort of appendage to the adjacent park. The entire area thus secured for the public service is obviously large, and will afford ample accommodation for the various departments comprehended in the scheme. Some anxiety will doubtless be felt as to the style of architecture. The *Standard*, with its usual anxiety to impart exclusive information, assures us:—"It will certainly not be that of the New Law Court." For the present we are told that the architectural features of the new building are to be subordinate to its main purpose as a great public office. No better principle could be enunciated. There is always elegance in fitness; but without doubt the commanding site thus obtained, presenting itself to public view on three sides, offers a tempting opportunity for the exercise of architectural taste." The *Standard* enunciates sentiments and principles with the facility of Joseph Surface himself. Let us hope that the architect who is selected to erect the new building may suffer less injustice and vexation than most of his predecessors who have served the Government.

OUR VERNACULAR ARCHITECTURE.*

MR. STREET'S speech to the Royal Institute of British Architects was a bold as well as a thoughtful one, and thoroughly creditable to him, as one of the chiefs of his profession; but it fails to convince us. We admire and applaud, without being satisfied that the speaker has touched the root of the great evil he denounces, or has suggested a practicable remedy. By a felicitous though unscrupulous little clutch, Mr. Street has appropriated a word from the terminology of the philologists, and calls the art of building without professional or scientific help, "vernacular architecture." "Indigenous architecture" would be nearer the truth, but "vernacular" awakens a more correct association of ideas. The infinite mass of English house architecture is, Mr. Street says, "vernacular," is due to the builder and the mason and the carpenter and the plasterer, all labouring by rule-of-thumb, and without any scientific or artistic supervision of any sort. Street after street is run up without any architect, till there are entire quarters large enough, if they only had histories, to be called cities, in the construction of which no trained professional has ever been consulted. The builders, who vary from great contractors, with science at their command, to little bricklayers working with borrowed capital, build them as they choose and can. Such building is almost invariably very bad, and this, says Mr. Street, must, in some degree at all events, be the fault of the trained profession. Architects cannot, as the law now stands, force builders to consult them; but they ought, by their example, to have taught the builders, to have given them ideas and an ideal, to have raised in them a general opinion, which would have made departure from the first principles of good architecture as discreditable as in many trades bad work is. Sound notions, in fact, ought to have filtered down from the profession to the trade, if the profession had done its duty, for they did once filter down. "Vernacular" architecture is no new thing; it must always have existed, and did exist; it is the badness of such architecture which is the novelty. A century ago, the English builder frequently built without help, but he had learned his trade from men who had been trained by the architects of that day; and his ideal, therefore, was a simple, solid building, entirely devoid of ornament, but full of utility, and certain to endure. Now builders build houses so thin that every word is heard through all walls, and so weak that the inmates rock in their beds when the wind blows high, and spend all their spare money on "so-called ornaments to the stucco fronts only of the houses, which are costly to put up, costly to keep in repair, and hideous in their ghastly unfitness for their place. They have compo keystones, ornamental railings and balconies, a few lumps of terracotta, elegant cornices and window-dressings, and highly suggestive chimney-pots." That is, Mr. Street thinks, the fault of architects, for if the builders who use their aid were trained to solidity, drilled into it through never seeing

anything else, they would, in their turn, train other and smaller men in the same idea, till adequate solidity was accepted as a *sine qua non*, as the builder's necessity, as a quality the absence of which would be held unworkmanlike and discreditable. Builders would be cut by builders for scamped work, as officers are cut by officers for ungentlemanly conduct.

Nothing could be sounder or more beneficial than such a speech, and we only wish Mr. Street could preach a course of sermons upon that text to all the builders of England; but we fear he would only make them wretched, without permanently amending their behaviour. If bad art and bad work and ugly ornament constitute badness, builders are very often bad; but there is an involuntary element in their badness, for which Mr. Street scarcely makes sufficient allowance. They can, if they like, abstain from stealing gravel—a direct theft, for which we hope yet to see a builder or two in Portland Prison—they can supply the seasoned materials they say they supply, and they can build perfect drains, instead of laying down, as they often do, pipes without connections to them; but whether they can build solidly may be doubted. They themselves say they cannot,—that the conditions now imposed by circumstances are too numerous and too inexorable, and that to demand solid building from them is to demand that they cease to build altogether; and they have a colourable case. All possible circumstances which could induce a decent builder to build houses so weak that they rock in a storm, appear to have arrived in this country together. In the first place, the freeholders of the soil, who have the first word in the matter, do not ask builders to build well, but almost insist, as a condition of employment, that they shall build badly. The freeholder of the last century, anxious for profit on his city estate, either sold the land to the builder altogether, or granted him a long lease at a comparatively moderate quitrent, and under a well-understood, though tacit agreement, that the lease would be renewed at a moderate, or, at all events, endurable rate of increase. The great Cavendish property, the present "Portland Estate," was all treated in this way, and for more than a century tenants were treated with a rare lenity and consideration on all questions of renewal. The builder, therefore, with a hundred years of tenancy to sell, besides a possible perpetuity, had every inducement to build solidly, and look to his purchaser for such profit as he expected; while the purchaser expected solidity, as much as he would have done had the house been freehold. Expenditure on the house might be scamped in places, but the "shell," the walls, and the beams, and the doorways were sure to be intended to last the century, and, as a matter of fact, have lasted, as witness Harley-street. Now, the freeholder, especially in the suburbs, possessed with the idea of a rapidly-increasing income, refuses long leases, picks out builders content with short terms, and very often succeeds in finding men who will "put up" houses, and even large houses, on leases of thirty-five years. It is hardly in human nature to build with true solidity on such a tenure as that, and the difficulty of doing it without heavy loss has been increased by other causes. All building materials have largely increased in price, not only brick, but timber, more especially timber for beams, and most especially timber for beams of more than a certain solidity. Then recourse has been had to poor timber-work, cut by machine, and manufactured or imported wholesale, while the price of all labour has increased enormously, till the effect of the triple process has, speaking roughly, been to alter completely the old proportionate cost of solidity and thinness. If the wall is doubled in thickness, and the beams are doubled in strength, and the doorways and windows are doubled in durability, the cost is not doubled, but tripled to the builder, who has to pay not only for more material and for more labour, but for material of a kind that grows scarcer, and more labour at a higher price; while he loses, as against his rivals, by the whole cheapness of the machine-made and imported rubbish. At the same time, he does not find that he can recoup himself in his prices. Wealth has increased, no doubt, quite as fast as the cost of materials, but not the wealth of the classes he builds for, much less their inclination to spend that wealth in purchasing solidity for a few years by a sacrifice of their capital. They would give double

money to be housed for ever in solid buildings, but they will not give it to be housed a little more comfortably for only thirty-five years, in the middle of which they will probably be desirous to move further afield. Among the classes living on earnings, the pressure of rent is so severely felt, that as they cannot buy freeholds, they insist on keeping rent down, and it is kept down by the sacrifice of solidity, which they do not greatly value, which the builder, with his short lease, greatly dreads, and which the freeholder, who never spends anything, but makes the next leaseholder do all repairs, cares nothing whatever about. As to the compo messes, and stucco window-dressings, and ornamented chimneys, the fault lies with the public, which will have them, though it knows perfectly well all the while that the cost of ornamentation must be taken out of the cost of what is properly "building."

Suppose, under these circumstances, that Mr. Street's sound and wholesome advice were successful, and that the builders were gradually convinced that solidity was indispensable, what would be the result? Clearly, either that the new houses would cost exceedingly much more, to the despair of tenants, who would declare that they could not pay such rents, and would not lock up capital in premiums; or that building would stop, and the people crowd together into the existing dwellings. That process is going on now to an enormous extent, particularly in the solid streets of the third rank, the houses in which are slowly parcelled out in floors, occupied by two or even three families, under an agreement which leaves one of them still the nominal owner of the house. That is not a good system, but it is one which, if houses are all to be solid, would very soon receive an immense impetus, till London gradually assumed the characteristics of a Continental capital. The remedy, we fear, is not in rating the builders, who will obey orders, like any other tradesmen, and build solidly, if they are only paid, but in a sweeping away of settlements which will allow owners either to sell sites, or to agree to the Scotch device of perpetual leases. The Scotch, who, except in Glasgow, are not cramped for room, and who have stubborn ideas of economy, will not build on a lease for less than perpetuity, and consequently their houses are for the most part fairly solid. Till we can get this change, there will be little improvement, and even then another will be required, which Mr. Street will probably not like. Architects are not bad people, and most of them have some artistic feeling, but still they are human beings, and while they are paid by a percentage they will never be heartily desirous of securing cheap solidity. They like the solidity well enough, but they like also to be paid; and a house which costs £10,000, costs the architect no more time or energy than a house which costs £5,000, while the architect's honorarium is very nearly double. Let the architect contract to supervise the builder as the builder contracts to construct the house, and his temptation will be steadily towards the cheap solidity which will ultimately make his name. As it is, the more the private customer spends, the better it is for the architect; while the builder, who ought to employ him always, is afraid of the cost.

VENTILATION OF DWELLING-HOUSES.

ON Wednesday evening, Mr. Henry Masters, architect, read a paper on "Ventilation," before the Bristol and Clifton Junior Architects' Society, at the Fine Arts Academy. Mr. Masters commenced by stating that his subject would be treated more in a practical than a theoretical manner, and apply more to the dwelling-house than public buildings. In his experience, he had seen more failures than successes, and felt regret that ventilation could not yet be considered an exact science. He pointed out some of the difficulties met with in the practice of ventilation, such as the exhaustive power of the domestic fireplace and chimneys in the room to be ventilated, as well as its power in other apartments; and also the influence of temperature, each of these powers acting in such a manner as sometimes to cause the air to go the contrary way to that wished. He then described Dr. Reid's method—exhaustion by a fire at the bottom of a

* From the *Spectator*.

especially-constructed chimney-shaft, and admitted air through a net of ice, and its application to the Houses of Parliament. Mr. Bernhard's system of zigzag pipes in an air-chamber, and as practised by the late Mr. Hazard, of Clifton, was explained, and its merits and defects commented on. Sir Humphry Davy's scheme of parallel pipes and cow-korn-exhauster was next described, also Dr. Arnott's attempt to ventilate a room by the heat of its inmates. Dr. Chowze's inverted air-siphon ventilator was illustrated, and the causes of its failure. Mr. Masters then pointed out the absolute necessity of air being kept in motion to insure good ventilation, and that the air should be obtained from a pure source, and cautioned his hearers to beware of obtaining it from marshy or damp ground, or the locality of bad odours. Nature abhorred a vacuum, and the cause of our rooms being so healthy as they were was due in some measure to the badly-fitting doors and windows and the exhausting power of the open fire and chimney endeavouring to form vacua. He also explained the tendency of air at times to pass down the one side of a chimney and up the other, which was a common cause of smoky chimneys. The approximate quantity of air required for each person occupying a room to insure freshness was given, and the difficulties in supplying this quantity, or any quantity, without draughts. The lecturer next described the inconveniences of the open fire, whereby the front of the body was scorched by radiation, and the back chilled by cold draughts. Reference was made to the air-chamber grates, and the care required in their selection so that the air should not be deprived of any of its oxygen in passing through them. Various modes of ventilating an apartment were described, and their good and bad points pointed out. The proper position for the admission and exit of air to and from an apartment was illustrated; some practitioners preferring it to enter at the top of the room, and drawn off from the bottom, and some to enter at the bottom, and drawn out at the top. The so-called Tobin's tubes patented by Mr. Whitehouse, architect, in 1794, were described, and their defects pointed out. The difficulty the architect will find to satisfy his clients in the matter of ventilation was touched upon. Sherringtonham's, Boyle's, and other ventilators, were referred to, and their points explained. Mr. Masters then described the mode he had adopted to ventilate local factories by exhaustion shafts and horizontal perforated tubes. Mr. Griffin's hinged door shutter was explained, and its merits of simplicity referred to, a patent having been recently obtained for it, although an old invention. He cautioned his hearers to be on their guard against certain ventilators in the market, and pointed out their very limited application and his early experience with his invention, the Archimedean screw ventilator. A few remarks were made upon a suggested mode of ventilating tunnels, if divided by a partition, whereby the train in its progress through would force air before it, and exhaust air behind it. Mr. Masters warned his hearers not to suppose his remarks, or the reading of books, were all that the young architect required to master the subject of ventilation, and he advised them to think the subject, well out, and test by experiment, and to get experience by studying the successes and failures of others. The paper was illustrated with a number of models and experiments.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

MANCHESTER ARCHITECTURAL ASSOCIATION.—The second meeting for this session took place in the old Town Hall on Tuesday, the 15th inst., when a discussion took place on "Sketches and Sketching," in which many of the members took part, and exhibited drawings—those by Mr. T. Rattee-Davies, calling for special notice.

NORTHERN ARCHITECTURAL ASSOCIATION.—At a special meeting of the Northern Architectural Association, held on Tuesday afternoon, in the Old Castle, Newcastle-on-Tyne, Mr. John Tillman, F.R.I.B.A., of Sunderland, was elected president for the ensuing year.

A new Corn Exchange at Truro was opened for business on Wednesday week.

Building Intelligence.

ACCRINGTON.—A new Conservative Club is now being erected in the centre of the town by local contractors. Externally the dressed asblar is from the Ringby Quarries, near Halifax, the wall-stones from Hipperholme in the same locality. The inside joinery is mainly of Baltic timber, selected pitch-pine being used for panels. Heating is to be effected by hot-water pipes on the low pressure system, and the ventilation by vertical flues in the walls discharging through the window-sills. Arnott's ventilators are also used. The cost of the building, excluding the site and furniture, will reach £200. The architect is Mr. Henry Ross, of Accrington, who is superintending the work.

CARDIFF.—New workhouse buildings at Cardiff, which have been erected at a cost of £23,000, are now ready for occupation. They include an administrative block facing the street and surmounted by a clock-tower 76ft. high; a dining-hall and kitchen; men's block to right and women's block to left of entrance-hall; laundry and wash-house; smiths' and shoemakers' rooms and an oakum-shed behind. At the rear of the administrative block is a disinfecting-room fitted with Leoni's apparatus. The dining-hall is 85ft. by 43ft., and is furnished with combined dining-tables and seats. The kitchen is 30ft. by 40ft. and is fitted up with five boilers and a large cooking-range; at the opposite end to the range is the scullery. Both the large blocks of buildings are three stories high, and are planned as day-rooms on ground-floor, with dormitories above, reached by stone staircases. The men's block is 117ft. by 40ft., and the women's 123ft. by 40ft. The fireplaces in dormitories are of glazed brickwork, and ventilation is effected by Tobin's tubes carried up separately in the chimneys. The laundry is 180ft. long and of various breadths. The total accommodation, including the refuge, is for 830 persons. Messrs. James Seward, and Thomas, of Cardiff, were the architects; Mr. Clark Burton was the contractor, and Mr. Williams, of Canton, near Cardiff, was the clerk of works.

MILNTHORPE.—On the 19th of last month Kitching's memorial hospital and reading-rooms were opened. The hospital has been built by Mrs. Bindloss, wife of the Mayor of Kendal, and will be kept up by that lady at her sole expense. The building has been erected as a memorial to her late father, Mr. John Kitching, M.R.C.S., L.S.A. Eng., who was a native of Milnthorpe, and practised at 61, South Audley-street, Grosvenor-square, London, for upwards of 30 years. The hospital will accommodate about 20 patients. On the same day was also opened the new reading-rooms for the use of the inhabitants of Milnthorpe, built by the late Mrs. Thompson Bindloss, of Castle-green, near Kendal. These buildings have also been erected as a memorial to the late Dr. Kitching by his sister. The Institute comprises reading-room, coffee-room, library, and a large handsome lecture-room; over these are billiard and bagatelle rooms. All the above buildings were designed and carried out under the personal supervision of Mr. Eli Cox, architect, of Kendal.

NEWHAVEN.—A new mission-church was consecrated at Newhaven on Monday, by the Bishop of Chichester. It is in the Early English style, and measures 96ft. in length and 48ft. across. It is built of brick, and consists of a nave and aisles included in one span of roof, with semi-octagonal apse at eastern end. The windows throughout are simple lancets with patterns of coloured brickwork in the heads. Above the west gable is a timbered bellcote. Internally the nave and aisles are separated by pillars and an arcade of massive woodwork—a similar arrangement to that which prevails in the parish-church at Newhaven. The open-timbered roof is strongly framed and braced to resist the heavy gales of the locality. The accommodation is for 500 worshippers, and the cost of builder's work, including spiral-stair, was £1,576. The church was designed by, and has been erected under the superintendence of, Mr. E. P. Loftus Brock, F.S.A., of Montague-place, Russell-square, W.C. Mr. J. Morris, of Ashurst Wood, East Grinstead, was the contractor.

STACKSTEDS.—New Church-schools were opened at Stacksteads, near Rochdale, on Saturday week. They are Gothic in style, one story in height, built in hard hammer-dressed stone, with tooled dressings of Rossendale stone; the high-pitched roofs are covered with Welsh slates in two colours. The boys' schoolroom is 52ft. by 30ft., and has two classrooms, each 18ft. by 14ft. 6in.; the girls' schoolroom is 60ft. by 30ft., and can be thrown into the boys' room as a T-shaped assembly-hall. There are two girls' classrooms, each 18ft. by 14ft. 6in.; the infants' room is 40ft. by 30ft., with 18ft. square classroom. Advantage has been taken of the slope of site to provide a parochial room, 30ft. by 18ft., and stone cellars beneath part of the schools. All the internal school-walls are plastered and provided with dados of Portland cement with moulded wood capping. The woodwork and exposed roof-principals are of pitch-pine; Shillito and Shorland's school grates are introduced, and also extraction shafts and louvre ventilators. The schools accommodate 700 children in three departments, and have cost, including parish-room grates and chimney pieces, and furnishing of lavatories and cloak-rooms, £3,400—under £5 per head.

COMPETITIONS.

BARROW-IN-FURNESS.—About fifteen sets of designs were sent in for the new board-schools at Barrow and Roose. At the first meeting of the board to decide, the plans of Mr. Holton, of Dewsbury, were selected for the Barrow schools, and Mr. Eli Cox's, of Kendal, for those at Roose. At a subsequent meeting the board could not agree, so they were referred to Sir James Ramsden, and he gave the final award to the first-named gentleman.

BIRKENHEAD.—A meeting of the friends and subscribers to the Wirral Hospital for Sick Children was held last week at the music-hall, Cloughton-road, Birkenhead, for the purpose of examining the competitive designs sent in by architects for the new building which it is proposed to erect in Woodchurch-road. The first prize was awarded to the designs of Messrs. Harvey, Pennington, and Bridger, and the second to Mr. John Clarke, and it is probable that one of these will be selected by the committee.

EVESHAM.—The town-council of Evesham recently advertised for plans for the addition of ante-rooms and lavatory to the council-chamber of town-hall, offering five guineas premium. At their meeting on Wednesday week the three plans sent in were exhibited in the room, and the premium was ordered to be equally divided between Mr. Reddale and Mr. F. W. Gardner. It appeared from the proceedings very uncertain whether either of the plans will be executed.

KENDAL.—Mr. Eli Cox, architect, of Kendal, was last week awarded first prize for the best set of plans for some extensive public buildings which are intended to be erected in Kendal. The site chosen is in the centre of the town, between Finkle-street and the present market-place. The designs show rows of shops facing both streets; the new markets will be in between these. The approaches from each street will be through four ornamental stone archways, of ample width and height, inclosed with wrought-iron gates. The interior of the market will be divided into four sections—viz., for fish, poultry, vegetables, and butchers' stalls. The section for fish is an notable feature, so arranged in the plans by the architect, that there will be no smell in the other part of the buildings from the fish, as this portion is inclosed with glass and wood partitions, and ventilated on the top by patent revolving ventilators. The style of architecture is Renaissance. There will be a tower facing each public street, in the centre of the buildings, surmounted by ornamental cast-iron gilded crestings, with the coat of arms of the borough introduced into the masonry below the tower-roofs. The architect's estimate for the buildings, including site, is £16,000. At the final meeting to award the premium the borough surveyor was asked to assist in the selection, when Mr. Cox's plans were chosen unanimously. The prize designs are now on view in the Town Hall.

"To a practical man with a taste for mechanics, and the humps of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the huge numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two-pence of all newsmen, or post free 24s.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

RECEIVED.—M. and Co.—L. and N.W.R. Co.—H. and O.—J. K. and Son.—C. H. and Co.—G. W.—G. W. Ry. Co.—C. H. S.—J. P. E.—A. S. and S.—R. R. A.

M. (You are right in the main; but if you had seen most of the others you would be thankful for small mercies, and look favourably, as we did, on a comparative if slight advance out of the ordinary run.)—SILENCE. (The series now appearing by Mr. Davies, or Mr. Buchan's book, published by Lockwood and Co., which also first appeared in these pages.)

"BUILDING NEWS" DESIGNING CLUB.

T. B. A. and OTHERS. (There are no fees in connection with this club. Small sketches may be sent.)—W. B. S. (Any one may join. The sectional parts of walls may be blacked.)—TOM. (The drawings are returned after the review has been published.)—SILENCE. (The subject for next time will be duly announced. "Silence" and many others are referred to the rules of competition, published in the BUILDING NEWS of Nov. 4th, p. 606.)

Correspondence.

THE DUBLIN MUSEUM COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—A letter—concise and pertinent—appeared in your last issue, which has attracted considerable attention; it is full of point appropriate to the occasion.

"Fair Play," the author, must leave the matter in the hand of the "Committee of Selection."

How that committee shall be constituted is not yet known to the competitors; it is hoped that conjecture can be the only present guide.

"Fair Play" has a few sympathisers; one at least who, while expressing his sense of the fairness of the lines that are set for competitors to follow, having felt some difficulty in interpretation of the requirements, yet has some timid hopes that his fellow competitors will be true to the honourable calling—one of trust—which they profess, and that they will refrain from adopting any of the usual artifices of competition.

"Fair Play" is sternly faced by some facts; one, that handwritings are usually recognisable by local friends; another, that the style of "getting up" drawings is known in a "set." Another, that previous to the announcement of the competition, designs were made, circulars were issued, interviews held with "eminent" representative of art and science, some of them not unlikely to be nominated upon the "Com-

mittee of Selection," by local architects who probably are competitors; and, further, that something of a similar description has occurred since the announcement of this competition.

"Fair Play" will, I trust, join me in the hope that the "Committee of Selection" will leave the issue to qualified and disinterested judges to report on the merits of the designs, taking the lines laid in the instructions to competitors, and on the suggestion that the decision shall be left to three members of the Royal Institute of British Architects—these to be nominated, say, by the president, or if he be a competitor, by the senior vice-president.—I am, &c.,
A LOVER OF "FAIR PLAY."

9th November.

PRELIMINARY SKETCH COMPETITIONS.

SIR,—Observing in two at least of the important competitions now before the profession that the terms of the final competition—"in which the author's sketch design, and no other, shall be fully matured"—render imperative the mere development of the preliminary sketches, the distinctive characteristics of which it is to be presumed will have led to their selection in the first instance, what chance, I would ask, will No. 10 or even No. 6 (the maximum and minimum numbers which may be selected in the Glasgow competition) have of overtaking Nos. 1, 2, or 3 in the final competition? With the chances so much against those at the lower end of the list, it would be only reasonable to give those of them who might so elect the option of accepting a smaller sum—say £50, for the labour incurred by them up to that point (those so accepting to withdraw from the final competition) and with the difference increase the amounts to be paid to those who choose to go on to "the bitter end."

Under the terms I have quoted, and considering the diversity of merit to be found in the first six or ten of competition designs in general, it would seem but a mockery and delusion to ask five or six architects to contend for a prize which is virtually awarded, and to expend time and labour on developing designs which in the ordinary course of things can be of no possible use; for, with the restriction mentioned would not the result of the competition be pretty well determined by the merits of the preliminary sketches?

I also observe that the remuneration offered for the final drawings in the Glasgow competition is at the rate of one shilling and one-fifth per cent.; in Dublin three shillings per cent.; and at Birkenhead about three shillings and sixpence per cent.; and this for drawings which will involve quite as much, if not more, trouble in their preparation than ordinary contract drawings.—I am, &c.,
A. B. C.

DWELLINGS FOR THE POOR.

SIR,—The provision of good and cheap dwellings for the poor in populous neighbourhoods, is one of the most momentous problems of the present day, and, although from the statistics which you gave last week, as furnished by the Dwellings Committee of the Charity Organisation Society, one would be disposed to take a somewhat gloomy view of the practicability of a satisfactory solution; it may perhaps be somewhat reassuring to know what has been, and can be, done in a provincial town.

It was stated (on the authority of Mr. Gatliff) that the cost of erecting dwellings may be taken at £52 per room, also that the Victoria Dwellings Association had provided accommodation at £171 per family, the Peabody trustees at £262 to £315 per family, and the Corporation of London at £305 per family.

We do not know whether pantries, w.c.'s, and wash-houses are included amongst the rooms which are said to cost on an average £52 each; but assuming that the wash-houses only are included with the living and bedrooms, and that the cost of the w.c.'s, pantries, &c., is thrown into the general amount, blocks of dwellings have been, and are being erected in Plymouth under our direction, in which, under similar conditions, the cost is only £32 per room (including cost of formation of roads also), and accommodation is provided at from £76 to £104 per family. In these buildings, too, there are no single-room dwellings.

Allowing for the difference between prices in London and those in Plymouth, we think this

shows a more hopeful aspect of the question, more particularly as some of the buildings have been opened, have immediately been let at about one-third of the London rentals, and pay a dividend of 5 per cent. clear.

The buildings are of a substantial character.—We are, &c.,
PLYMOUTH.
HINE AND ODGERS.

LIME AS A PRESERVATIVE OF IRON.

SIR,—Lime, per se, does not prevent the oxidation of iron. If iron is properly protected from contact with atmospheric air and moisture, oxidation cannot occur. If lime is therefore placed upon the surface of iron in the form of plaster, its absorption of carbonic acid from the atmosphere reduces it to a hard coating of carbonate of lime, impervious to air, and as long as the coating is intact, oxidation of the iron is prevented; but as soon as any portion of the coating is broken, oxidation actively occurs, and throws off the remaining portion of the lime; moreover, if the lime becomes moistened, it is useless as a protector of iron. The writer knows several instances in which lime appears to have increased corrosive activity, and as for mortar, it is a mistake to place it in contact with iron, if the former is exposed to atmospheric contingencies.—I am, &c.,
A.M. Inst. C.E.

TESTING TRAPS.

SIR,—I notice a letter in your last issue from Mr. Emptage, to which I must take some exceptions.

Firstly, he couples my name with Mr. Pullen's, and, as that gentleman and myself are not in any way connected, I fail to see on what grounds he has taken such a liberty.

Secondly, he makes an assertion to the effect that there are 18 in. between the plug in basin and the water-line in trap. Now, this is a deliberate and wilful pervarication of the truth.

Thirdly, as this gentleman has told me that he is not a plumber or engineer, I would like to know what weight can be attached to his opinions, and why I should be pestered week after week to answer his letters? The experiments that have been made at Mr. Pullen's, have been witnessed by many of the best practical plumbers, &c., in London, which, I should think is much more trustworthy than if, as he requests, at the finish of his last letter, that your readers would suspend their judgment, awaiting his explanation next week. He must remember that he has, first of all, to explain away the falsehood. In conclusion, I emphatically assert that everything in my article on page 510 is perfectly correct; and, again, only to-day, I have tested all the traps with a valve-cloth seated directly on the top of each individual trap, as were also the basins in my former experiments. The action proved to be precisely the same.—I am, &c.,
P. J. DAVIES, H.M.A.S.P.

P.S.—It is just possible that Mr. Emptage may, like many others, be under the impression that I am personally in the manufacture of the U-trap; this, however, is quite a mistake, as I never manufactured a single trap, excepting for my own contracts, nor do I intend to supply them. I have, in one of my articles, given full instructions and measurements as to how the U-trap should be made, and those who want them for themselves can get them elsewhere.

SIR,—Allow me, for the benefit of your readers, to say that I have watched the correspondence between your able author of "Practical Notes on Plumbing" and others, and to also endorse the facts given, that the basins were, when I saw the experiment made (I was there, but gave the name of Wilson), fixed direct upon the traps. I measured the distance from plug to water-line in U- or round U-trap, and this is from my pocket-book taken at that time. "Dent U-trap top of scaffold; basin fixed over U-trap, total height from floor-line, 15 in.; depth of basin, 12 in.; from plug to water-line, 6 in." So that Mr. Emptage last week is wrong when he writes the basin to be 18 in., the trap momentum out each time.

Many thanks for Mr. Davies' splendid articles on plumbing; they make one fancy being at work when I read them.—I am, &c.,
PLAY FAIR.

SIR,—I was greatly surprised at Mr. Emptage's assertion in your last issue, that the distance from the plug of closet-basin to water-line of Beard and Dent's trap was 18 in. I flatly contradicted him on this point, as when I saw the tests a fortnight ago the basin was fixed at the ordinary height; however, to make assurance doubly sure, I again visited Mr. Pullen on Saturday afternoon, and found that the height from plug to water-line, when the basin was

fixed at its proper height, was 9in., and when placed direct on the trap 6in.; and, moreover, than that, with a valve-chuset fixed at the usual height on one of the Beard and Dent's trap, and with a 1 1/2in. air-pipe off the heel of the trap, it still washed out and left the trap unsealed. I hope, for the sake of Mr. Emptage's patrons, that the experiments at the Dame-hill Sanitary Works are carried out with more care than he appears to have given to these tests.—I am, &c.,

R. SMITH,
Secretary Plumbers' Society, St. Martin's-lane,
43, Bermondsey-square, S.E., Nov. 11th.

TESTING TRAPS.

SIR.—Mr. Emptage has made a great mistake in the measurement between water in ∞ -trap and the plug in basin, it being only 6in. instead of 18in.—I am, &c.,
160, Cromwell-road. A BUILDER.

SIR.—As a plumber of twenty-five years' experience, I was very much astonished at the statement of Mr. Emptage, about the height of the closet-plug above the water in the testing of Beard and Dent's trap. I measured it myself, and found it 9 1/2in. instead of 18in., as he states.

I think it would be better for Mr. Emptage, before he rushes into print, to learn to be accurate, and also gain a little more experience before he arrogates to himself the style and title of "sanitary engineer."—I am, &c.,
J. BARNEY.
25, Alfred-street, Grange-road, Bermondsey, Nov. 14th.

SIR.—I am somewhat surprised at the statement of Mr. Emptage, in your issue of the 11th, that the distance from plug in basin to water-line of ∞ -trap was 18in. The gentleman must have been drawing on his imagination for his facts, as the greatest distance was carried out 6in. from water-line of trap. I trust he will be more accurate in future, and as he is welcome to visit our establishment again to correct his measurements, he will do so and make his correction as public as his curious statement, for contradictions of assertions in this manner are far from pleasant.

I must also remind him that his meeting Mr. Davies at our works was not sufficient to warrant his connecting that gentleman's name with our firm. I only know Mr. Davies to be a thorough plumber, whose only connection with us is the unity of ideas, the result of training in sanitary matters from our youth upwards.—I am, &c.,
J. PULLEN, JUN.,
(Of the firm of Pullen and Son).

73, Penton-place, Waltham, Nov. 14.

P.S.—I cannot close this letter without reminding Mr. E. that I personally asked him if he knew of any other test to which we could apply the traps, and he answered, "No"; and to another inquiry if he was satisfied that our tests were fair to all the traps, his reply was, "He considered we had done everything fair."

SIR.—I have received a letter from Mr. Davies, calling my attention to a statement made in my letter upon page 611—viz., that there was a drop of 18in. between the valve and water-line of ∞ -trap. On reference to my pocket-book, I find it so stated. Upon consideration, however, I am inclined to think it is an error, as the valve and branch piece being both fixed, the drop must have been about equal with all the traps—viz., about 1 1/2in. I regret very much the error, which was quite unintentional.—I am, &c.,
DANIEL EMPTAGE, S.E.

Margate, Nov. 16th.

[Perhaps in future Mr. Emptage will have some consideration for our space, and be careful before writing.—ED.]

The new building erected by the Corporation of Stafford, from designs by Mr. J. B. McCallum, the borough surveyor, for the purposes of a Museum, Free Library, and School of Art, was formally opened on Thursday week. The building is situated in Eastgate-street and adjoins the Borough Hall. The library and reading-room occupy the ground floor, and the first floor is taken up by the Wragge Museum, leaving the second floor for the Art and Science School. The dimensions of the rooms are 37ft. by 37ft. The frontage is composed of red brick, with ornamental designs in terra-cotta, supplied from the Brereton works of Mr. Arthur Gee, of Stafford, the contractor. The work, which includes some scrolls and medallions in terra-cotta, has been completed by Mr. Gee at a cost, exclusive of site, of £2,000.

The three-light east window of south aisle in Great Shelford parish-church, has just been filled with stained glass as a memorial. The subject is our Lord delivering the Sermon on the Mount. The work has been carried out by Mr. W. H. Constable, of Cambridge and London.

Entercommunication.

QUESTIONS.

[6767].—**Fixing Weather Tiling**.—What is the proper method of fixing weather tiling to brickwork? Also, what is the usual one? Information in reply will oblige.—W.

[6768].—**Fifteenth-Century Plate-Armour**.—What are the accepted terms for the main portions of armour worn in the 15th century?—A STUDENT.

[6769].—**Early-English Woodwork**.—Where are the best old examples of this period to be met with? Mr. J. R. Collings, in his examples of "English Medieval Furniture," gives many illustrations of stonework of that period, but not a single instance of wood dating from the 13th century.—A STUDENT.

[6770].—**California and Colorado**.—I would feel much obliged to some reader for information about California and Colorado. Would a young man who has had a good architectural training, is well up in construction, can take levels, and fairly up in land surveying, have a fair prospect? I shall be thankful for any information, but it be ever so small.—TEX.

[6771].—**Deadening Sound**.—I have recently built a pair of villas with 9in. brick party walls, through which sounds are heard very distinctly. Would thin lead under the finished wallpaper assist in deadening the sound, or is there any other simple and economical method of curing the defect complained of?—MANCUNIAN.

[6772].—**Timbers in King-Post Roof**.—In Livingston's "Building Construction," in a table of scantlings of timbers for a king-post roof truss, I find: Span, 20ft.; tie beam, 9in. by 4in.; king post, 4in. by 3in.; pl. rafter, 4in. by 4in.; struts, 3 1/2in. by 2 1/2in., &c., and a note: In practice the width of the K.P., tie beam, and struts generally made the same as that of the tie beam. Would one of your correspondents kindly let me know which of the two sizes are considered the width?—R. F. S.

[6773].—**Deflection of Lattice Girder**.—How should the safe deflection of a lattice girder be calculated? Suppose it is being tested to a fifth of its breaking weight, what should the greatest deflection be? I shall be glad of the name of a good work bearing on the subject.—TUBAL.

[6774].—**Bank**.—Will some of your correspondents kindly furnish me with the requirements of a head office for a Corporation bank, and the position at that the various officials should have to each other?—MINT.

[6775].—**Transferring Oak Carving to Paper**.—Would a correspondent advise me the best mode of transferring oak carving on to paper?—NORTHEAST STUDENT.

[6776].—**Moss on Wall**.—Will some reader kindly say by what means I can remove the moss from the walls of a church in the country? There is a lot of ashlur blue whinstone, with dressings of white cut sandstone. Is there any chemical wash that would answer?—Z.

[6777].—**Measuring Chimney Breasts and Stacks**.—Could any reader kindly say how the brickwork to chimney breasts and stacks is measured in Yorkshire, whether measured for labour only or labour and material? Whether the breasts be built solid or not?—MOWBRAY.

[6778].—**Drain**.—I have a plot of ground where, in wet weather, the water stands to within 4ft. 6in. of ground line. As it floods some basement floors to the depth of 1ft., and is impracticable owing to other buildings to lay a drain direct from the cellar, would it be practicable to lower the water-line by sinking a well at a distance of 40ft. from cellars, and lay a drain with sufficient fall to main drain in road. There is gravel below ground line to the depth of seven feet.—MOWBRAY.

[6779].—**Measuring and Charging**.—Would H. McCallum or "G. H. G." answer the following? When you have finished a job for which you have had "quantities," when you measure the work at the completion, do you make out a fresh "bill of quantities," with the measurements of the work as executed, including all extra works kept separate in the bill? Do you deduct all "provisional items" on the credit side of statement, and add the contracts or cost of the work for which these amounts were provided on the debtor side? Or do you go through cost of the work for which, say, £10 was provided, and you find by measure and value, at same rate as quantities, it only reaches £8, do you give them credit for £2 without any particulars? I should be exceedingly obliged if you would give me some information as to the correct manner of making out a statement of work after the contract is completed. If you found when you came to measure up the work as actually executed that for an item of, say, 450 yards of brickwork, in quantities there were only 12 yards in the work, should you give credit for this or not take any notice of it? If you had a contract, and there had been variations in it, and there was doubt in your mind as to whether variations or deductions with any small extras you had done would come to the most, what would you do?—STUDENT.

[6780].—**Extras**. I take a contract for plastering from quantities supplied by an architect. During the execution of the works the architect gives me verbal orders for extra work in sizes of corners and enrichment. The order is given in the presence of my own men. I cannot claim my schedule price for the extra work, and are not my own men who heard the architect's order given sufficient witness in place of a written order from the architect?—L. NORMAN.

[6781].—**Lager Beer Breweries**.—I am desirous of studying the planning and arrangements of the above breweries (German or American), and comparing the same with our malt beer breweries for the purpose of ascertaining by how much alteration the latter can be made adaptable for the purposes of the former, therefore I shall feel obliged if Mr. Hugh McCallum or others of your readers will advise me what books are obtainable? Also any further advice will oblige.—A YOUNG SUBSCRIBER.

[6782].—**Architect's Charges**.—A client of mine

bought at second-hand an iron church. It had been taken to pieces. Whilst in that state and from what I could make out from the man employed to take it down, I had to make the plans required by the Metropolitan Board of Works. Taking into consideration the circumstances mentioned, I should be glad to know what would be a fair charge to make. The plans, owing to the building being in pieces, were difficult to make correctly, and several were necessary before the Board was satisfied. There was, of course, also a set to be made for the District Surveyor.—A DENTON.

[6783].—**Builders' Estimates**.—A builder executed a contract for a client of mine under my supervision, and during the progress of the work was requested by me, as architect, on behalf of the proprietor, to give estimates for several extras, some of which, however, were accepted. The builder's accounts were made up and final certificate given twelve months since, and the builder now sends me a bill charging excessive sums for furnishing the estimates referred to, as a set off against an account (apart from the before mentioned contract) I have against him. Can he charge for estimates, and, if so, am I liable? A reply to this query by a reader will oblige.—ARCHITECTUS.

REPLIES.

[6752].—**Zinc Roofs**.—The edges of the zinc are sometimes turned up so as to form 1 1/2in. rolls, if they may be so called. They can be trodden upon without being injured. The wall flashings should be pointed with cement, not mortar; the latter affects zinc in some way. I have heard that the urine of cats is injurious to zinc. I should be glad to know if this is so. Zinc lasts about thirty years in London.—C. F. M.

[6759].—**Notice to Quit**.—I should consider the circumstances mentioned to be an acknowledgment of sufficient notice unless there was an understanding that it only held good on a new tenant coming in. Moreover if "F. W. H." could not prove all the particulars of his statement he might be held liable for further notice.—HUGH McCALLUM.

[6760].—**Sp. G. and Crushing Weight of Corsehill Stone**.—As I have had the pleasure of introducing into the London market Corsehill stone (which is the best red stone of the whole Dumfriesshire series), I reply to "Veritas" that its specific gravity is 2.262, the weight per foot cube is 141lb., and the mean crushing weight of three samples as given by David Kirkaldy is 5006 tons per square foot. I enclose printed copy of Kirkaldy's report. I add that Corsehill stone is in large demand, the quarries sent out during the past year 210,000 cubic feet of stone.—SAMUEL TRICKETT.

RESULTS OF EXPERIMENTS TO ASCERTAIN THE RESISTANCE TO THRUSTING STRESS OF THREE GIN. CUBES OF STUMP, RECEIVED FROM SUMMIT TRUCKEE, ESQ.

All bedded between pieces of pine 2 in. thick.

All bedded between pieces of pine 1in. thick.

[6761].—**Chimney**.—Does "Young Builder," by inner casing, mean a lining independent of the walls of shaft? If so, I would not recommend it. Either for strength or usefulness, unless there is a large space between it and the wall, because it will get filled up with soot and dust, and it must be tied to the outside wall, or the usual half brick thick, which is the general rule, will not carry the weight of its own load if any considerable height. Some people build the lining independent, to allow for expansion; but if tied to the outside wall, both must expand, then what is the use of the space? My idea of chimney construction is that the flue should be circular inside. The outside may be any form, and the top of flue should be of greater sectional area than the bottom, be-

cause the air is at a higher temperature when it enters than when it leaves the flue, consequently the velocity is less at the top than the bottom, provided it is not impeded by throttling at the top. There have been five chimneys constructed during six years under my supervision, four octagonal and one circular, each standing on square base. They were designed to suit the tastes of the owners, and principally to imitate others surrounding them. They all have circular flues. The circular shaft was the only one where I could adopt the flue section named above, on account of the diminishing of the outside section. This chimney is 115ft. high, 2½ brick wall at the bottom and one brick at the top, including lining, which is carried three-quarters of the height, and bonded into the outside walls, every 1ft. 6in. in height, with a course of headers and a hoop of wrought-iron, 3in. by 2in. bar, built in every 4ft. in height and within half-brick of the outside; the flue at the bottom is 4ft. 3in., and at the top 5ft. 3in. diam.; the top is covered with a cast-iron cap, 11ft. 9in. diam. outside, 4ft. 6in. high, weighing 93½ cwt., built up of 38 pieces, and filed in solid with brickwork; the brickwork was built in hydraulic lime mortar; it has been standing five years, and is as perfect as when first built. I consider the hoops are essential to a good construction. There is a chimney standing near to this one 150ft. high, the proportions similar to the last one, with cap 20ft. diam., walls 2ft. 4in. at the bottom and 1ft. 2in. at the top. This chimney has been standing 24 years, it has 24 boilers attached to it, all working at one time, and consumes 73 tons of coal in 24 hours. About six years ago it began to show signs of cracking, so it was hooped outside every yard in height round the circular shaft, and is perfectly safe now. I don't think it improves the appearance of a shaft when it is tapered so much, and it certainly is not so strong, because the surface is reduced where it ought not to be, both for resisting wind-pressure and carrying the load above. I have seen a pair of chimneys taken down about one-third from the top because they were buckled and both leaned to the east, and apparently were top heavy; they have put on smaller caps, which is no improvement in appearance, considering the height.—B. S.

[6765]—**Glazed Earthenware Flue Lining.**—I have a chimney about 45ft. high lined with 9in. glazed drain-pipes the whole height. No fall of soot has occurred during the four years it has been in use.—SATISFIED.

[6765]—**Glazed Earthenware Flue Lining.**—In answer to "Smoke," I have not had any practical experience of glazed flue piping, but I have no doubt the objection he anticipates is well founded. I have used for some time past the ordinary unglazed stoneware piping, and it certainly does cause a great deal of soot, in fact, no soot at all adheres to the flue. Doubtless the glazed surface would be much worse in this respect. I presume the theory of these matters is that with a good draught all the soot and smoke passes through the flue and out at top, being non-adherent to surfaces of the flue. I greatly doubt if this is practically the case, but I trust "Smoke" will have a reply from some more experienced party than—B.

LEGAL INTELLIGENCE.

SPECULATIVE BUILDING AT BEDMINSTER.—At the Bristol police court, on Wednesday, before Messrs. S. Wills and T. Wedmore, Charles Boon was summoned to show cause why he should not be committed to prison for not obeying a magistrates' order to pay £74 to the Sanitary Authority in respect of pitching and paving streets fronting houses belonging to him, and costs. Mr. Hooper, on behalf of the Sanitary Authority, said the defendant was ordered a considerable time ago to pay the sum, and paid £39 of it. He had been given time to pay the balance, and at the beginning of November, Mr. Salisbury, solicitor, who had been acting on behalf of Boon, said he hoped to make some arrangement. On the 3rd of November, however, Mr. Salisbury said he was sorry he could do nothing, and consequently an execution was put into Boon's premises, but the officer was met by a bill of sale for £55 odd, executed that day. Boon was sworn and examined by Mr. Hooper. He said he had a number of houses in different parts of Bedminster, but all were fully mortgaged. He had done about £40 worth of work for Mr. Bishop, and had received some of the amount in building material and £10 in cash. He had done about £130 worth of work to houses in Cabot-street. He, however, had had to pay the workmen, and had not received any benefit from the money himself. He was owner of the "Try Again" beerhouse, Sydney-street, Greenway Bush-lane, but that was mortgaged, and the bill of sale to which Mr. Hooper had referred covered the furniture, effects, and goodwill. He did not know when he should be able to pay the money to the authority, for by putting in the execution his credit had been damaged. He filed his petition in liquidation on Saturday last. Mr. Salisbury acted for him in these liquidation proceedings. The bill of sale was in respect of £55 odd advanced by a client of Mr. Salisbury to enable him to take up certain building grants. Mr. Salisbury, who appeared for Boon, said the defendant had been in struggling circumstances for some time. His property was mortgaged up to the full value, and he doubted if some of the houses would realise as much as was advanced on them. He advanced £510 on six houses in Murray-street, and it was necessary, in order that that security might not be sacrificed, that the building grants of these properties should be given up. A client of his accordingly advanced the £55 odd to enable these grants to be taken up. Mr. Hooper pointed

out that Mr. Salisbury held an equitable security for his advance but one that could not be realised till the grants were taken up. His (Mr. Salisbury's) communications to the Authority led to delay, and in the meantime the bill of sale was executed, Mr. Salisbury's security made negotiable, and the authority shut out. Had there not been the delay the authority could have levied unimpeded by any bill of sale. Mr. Salisbury said he had paid several creditors of this man, and hoped to have paid the sanitary authority. He simply told the authority he wanted a little delay so that he might investigate his affairs and see if any further advances could be made on his property, and after that investigation had been made it was found that Boon must file his petition. The authority had had half of their money, so that they were much better off than many of the creditors. Mr. Gore said Mr. Hooper must show that the defendant had had, since the order was made, means to pay the money. The bench intimated that they were not satisfied that this proof had been given, but on the application of Mr. Hooper the matter was adjourned for a fortnight.

ALLEGED SLANDER.—(Supreme Court of Judicature—Court of Appeal.—Sitting at Westminster, before the Lord Chief Justice, and Lords Justices Baggallay and Brett. Griffiths v. Holloway—Griffiths v. Steel).—These were actions for slander. The plaintiff was a contractor for paving roads, and the defendants, who were builders, were also vestrymen of the parish of St. Leonard's Shoreditch. It appeared that at a vestry meeting held on the 24th of February, 1880, at which a tender of the plaintiff for paving the parish for the next year was under consideration, the defendant Holloway, speaking as a vestryman, made use of the following words with regard to the performance of a previous contract by the plaintiff:—"St. John's-road was grouted simply with black mud," meaning thereby that the plaintiff had used improper material for grouting. The defendant Steel, who was also present at the meeting, was stated to have got up and observed, "I can corroborate that statement. St. John's-road was grouted with garden mould, which was carted from a garden in Hoxton, and I watched the carts from where it was brought." It appeared that in 1879, when the plaintiff was carrying out a paving contract for the Vestry the defendant Holloway having noticed what he thought was inferior material being used for grouting, directed the attention of the defendant Steel to the matter, and they together brought the subject before the Paving Committee, who appointed a further committee (of which the defendant Holloway was a member) to investigate the whole subject. At the investigation a surveyor stated that the material complained of was a good material, and had been in use for some years, and in the result the committee reported that there was no foundation for the charge. In consequence, the defendants, who were dissatisfied with the surveyor's statements, and thinking that the plaintiff had dealt unfairly in the contract of 1879, uttered at the vestry meeting in question the alleged slanders complained of. The plaintiff wrote asking that the words complained of should be withdrawn, and upon the defendants' refusal to do so, brought these actions. At the trial of the actions, which were tried together, before Mr. Justice Grove and a special jury, the learned judge laid down that the occasion was privileged, and left to the jury merely the question whether there was evidence of malice on the part of the defendants. The jury found a verdict in favour of the plaintiff, with damages £40 in each case. A Divisional Court having granted a new trial on the ground that there was no evidence of malice, the plaintiff appealed to this court. After a prolonged argument, their lordships reserved judgment.

JERRY BUILDING AT FINCHLEY.—Edwin Watkins Smith, builder, of Hamilton-road, Finchley, was summoned last Monday, at Highgate, for infringing the by-laws of the Finchley Local Board, by using inferior materials in the construction of the chimney stacks of six houses at Finchley, and further, with not depositing the plans of the houses with the Board.—Mr. Stevens, solicitor to the Board, prosecuted, and stated that this was a very bad case, and since the Bench adjourned it to see whether the defendant fulfilled his promise to amend all the defects complained of, he had stuck small pieces of iron into the chimneys and replastered the fronts to make it appear as if he had done so, but had not done anything the Board required. The defendant admitted this statement, and said that it would be dangerous to pull the old bars out so as to replace them with new ones, as required by the Board. Mr. Bodkin said it seemed hardly fair to builders that they should be allowed almost to complete their houses before they were summoned for not complying with the Local Board by-laws. Only a little time since a builder was summoned with respect to twenty-seven houses, and as the proceedings were not taken until the houses were finished it was necessary to pull a portion of them

down so as to remedy the defective parts. Mr. Stevens said it would want a dozen surveyors to watch the progress of all the houses in construction in the parish, and assured the bench they took immediate action in all cases brought under their notice. Mr. Bodkin said if there were not sufficient persons to do the work others ought to be appointed. It seemed to him that action ought to have been taken earlier, and it was a great pity the local boards had not the power to stop building work when they found it was not being carried on in accordance with the by-laws. However, the defendant in this case had clearly infringed them, and then tried to deceive both the board and the bench, and he would be fined £5 and costs on each of the two summonses, including the solicitor's and surveyor's fees—in all £14 14s. The defendant asked for time to pay the money, but his application was refused, and the clerk told him unless he paid it at once a distress warrant would be issued.

IN RE GREEN.—(Before Mr. Registrar Murray.)—Mr. Yetts applied, under a petition for liquidation, presented by Robert Green, builder, contractor, and farmer, of Elm-grove, Lower Norwood, for the appointment of Mr. A. H. Lavers, of Nine Elms, as receiver and manager of the business, and also for an injunction to restrain several actions. The debts were returned at £23,700 in the aggregate, of which about £11,000 was unsecured, with assets about £25,900. The application was supported by creditors, and His Honour granted the order.

ST. MARY-AT-HILL CHURCH—FACULTY REFUSED.—**PEEK v. TROWER**—(Archdeacon's Court. Before Lord Penzance, Dean).—Judgment was given in this case, which was an appeal from the Consistory Court of London, granting a faculty to the rector and churchwardens to make alterations in the interior of the church of St. Mary-at-Hill, at an expense of about £500, out of the parochial funds.—Sir H. Peek, M.P., one of the patrons of the living, opposed, on the ground of the alleged wasteful expenditure, and that pending legislation under the Royal Commission on the City Parochial Charities the church might be abolished. Since the report of the case on the 27th ult. Lord Penzance had viewed the edifice. Lord Penzance, whose judgment was read by the Registrar (Mr. Moore), on account of his indisposition, after stating the facts of the case, said it was intended to lower the tops of the pews, to slope their backs, and make them more comfortable; to move some of the pews, and raise the floor of the church. The church was built from a design of Sir C. Wren, and taste differed as to pews. Some were for high backs, and some for low backs. It was a mere matter of taste and fancy. In the last ten years the population of the parish had decreased from 616 to 287, and out of 60 ratepayers, 48 opposed but were non-residents. After deducting the choir and the caretakers of the warehouses, the congregation of parishioners was very small indeed. In his opinion the court ought not to sanction the proposed alterations in the absence of a clearly-expressed opinion of a sufficient body of parishioners, and, under all the circumstances, he saw no reason to interfere with the existing arrangements of the old church. The order of the Court below must be reversed, and the faculty refused. His lordship made no order as to costs.

IMPROPER BUILDING MATERIALS.—At the Edmonton Petty Sessions last week Caleb Champion, builder, of St. Anne's-terrace, Tottenham, was summoned for not complying with by-law 12 of the Tottenham Local Board, in the materials used for the construction of two houses now in course of erection on the Markfield estate, Stamford-hill. Mr. de Pape, surveyor to the local board, produced samples of the mortar taken from the walls, and stated that it was not a proper material for the purpose. Defendant, who said his foreman used the bad mortar without his knowledge, was fined £5 for each offence, with 10s. costs.—Arthur John Keeler, of Stamford-hill, was summoned for a similar offence in the construction of two houses on the same estate, and Mr. de Pape, having proved that the so-called "mortar" contained very little lime, and that defendant persisted in its use after being warned, he was fined £5 with costs for each house.

THE TRINITY HOUSE CORPORATION v. THE METROPOLITAN AND THE METROPOLITAN DISTRICT RAILWAY COMPANIES.—(Middlesex Sheriffs' Court.—Before Mr. Under-Sheriff Burchell and a special jury.)—In this case the claim exceeded £20,000.—Sir John Hulker, Q.C., and Mr. Vaughan Williams were for the Trinity House; Mr. Webster, Q.C., with Mr. Graham, represented the railway companies. The claim was in respect of several houses and land on Tower-hill, near the hall of the Corporation, and a claim arose in respect of an "easement" for tunnelling. The jury had previously viewed the property, and both sides agreed to try by eight jurors. For the Corporation the estimates were:—Mr. Horsey, £17,742; Mr. P. Anson, £18,897; and Mr. Chatfield Clarke, £17,567; to which was to be added 10 per cent. for compulsory

sale. For the companies, Mr. Alderman Ellis (the Lord Mayor elect), £11,820; Mr. Clifton £11,850; Mr. Farmer (Debenham, Tewson and Farmer), £12,000; and Mr. Lowe, £11,755. These sums were without the customary 10 per cent. Mr. Under-Sheriff Burchell directed the jury that the claimants were entitled to a full compensation for the property, and when they had arrived at a fair amount they would add 10 per cent. for a forced sale. The jury, after consulting for half an hour, assessed the value, including £200 for easement, at £14,559.

STATUES, MEMORIALS, &c.

YORK.—Last week a presentation was made to a highly respected citizen of York—Mr. William Pumphrey—in recognition of many services rendered to the city. The presentation took the form of an illuminated address, together with two articles of library furniture, designed specially by Mr. W. H. Thorpe, architect, of Leeds, and executed in wainset oak. They consist of a handsome library table with drawers in each pedestal, and a bookcase, each containing elaborately carved panels, with the City arms and Mr. Pumphrey's monogram.

STAINED GLASS.

JERSEY.—A stained-glass window has just been erected at St. Mark's Church, Jersey, for the Rev. H. M. C. Price. The window is an eight-light, and has been executed by Messrs. Gibbs and Howard, of London. The lights contain foliated ornamental canopies and bases on alternate ruby and gray grounds, and contain each a subject illustrating a scene from the life of Our Lord, and finally depicting his glory as King and Priest, surrounding by adoring angels holding palms, the tracery containing worshipping angels amid foliated ornament.

WATER SUPPLY AND SANITARY MATTERS.

GLOUCESTER.—The town council have recently received reports from Mr. J. F. Bateman, C.E., of Westminster, and Mr. Read, their borough surveyor, as to the progress of the boring operations at Birdlip. Three borings have been made, and the sand above the blue lias formation was reached at respective depths of 165ft., 184ft., and 51ft. from the surface, yielding in each case a supply of good water, which, up to the present time, was abundant. The cost of the experimental borings was about £250, and the results were satisfactory; and the town council were now asked to sanction the cutting of a tunnel between the two deeper borings. The engineer and surveyor were authorised to proceed with the works.

MARKET HARBOUROUGH SEWERAGE.—The plans for the main sewerage of Market Harborough, and the adjoining parishes of Great Bowden and Little Bowden, in the counties of Leicester and Northampton (these parishes forming a united district under one Local Board), having been approved by the Local Government Board, a contract, amounting to £11,500, has been entered into with Mr. G. Stevenson, of Evington, near Chesterfield, for carrying the plans into effect. The works are now being executed under the direction of Mr. J. B. Everard, of Leicester, the consulting engineer, with Mr. E. G. Mawbey, the surveyor to the board, acting as resident engineer and clerk of works.

MEXBOROUGH SEWERAGE SCHEME.—Mr. J. T. Harrison, C.E., held an inquiry at Mexborough last week respecting an application which had been made by the local board for sanction to borrow the sum of £11,000 for works of sewerage and sewage disposal. The clerk (Mr. Verity) explained the steps which had been taken by the local board to have an efficient scheme prepared. In answer to the inspector, he stated that the population of the township in 1871 was 4,316, whereas at the last census it numbered 6,411. The ratable value of the township was £2,415. The existing debt consisted of loans for the Market Hall and street improvements, amounting altogether to £7,302 17s. 8d. The engineer, Mr. White, stated that his mode of dealing with the sewage was by gravitation into a receiving tank, which would be capable of holding eight hours' supply of sewage, without pumping. This would be at the rate of 2 1/2 in per head per day. He estimated the total cost of the scheme at £17,500 17s. 11d. A report will be made to the Local Government Board.

GOVERNMENT INQUIRY AT DONCASTER.—Captain Hildyard last week held an inquiry at Balby respecting an application made to the Local Government Board for sanction to borrow £10,000 for sewerage and sewage disposal in the parishes of Balby and Doncaster. It was explained that it is proposed by the scheme to partly divert the sewage by its own

gravitation and partly by a pump, the motive power of which will be a wind-engine, and the sewage, after being allowed to settle, will be distributed upon land to be purchased from Mr. W. Aldam, chairman of the rural sanitary authority, and situate on the south side of Balby. Evidence was given at length by Dr. Wilson and Mr. Wright, the surveyor, the former on the necessity of a scheme, and the latter in explanation of the one proposed. There was some opposition to the land proposed to be purchased, one person stating that it was unsuitable, and the scheme would be a failure.

CHIPS.

The building of a new church has just been commenced at North Bralley, Somersetshire. The contractors are Messrs. W. and F. Long, of Bradford-on-Avon.

The contract for the erection of the Tay Bridge has been given to Messrs. Arrol and Co., of Glasgow, who carry on extensive works, and are at present engaged in erecting a large railway viaduct at Montrose. Mr. Arrol arrived at Dundee on Wednesday, and was engaged with Mr. Barlow, C.E., selecting sites for the erection of workshops, &c. Messrs. Arrol are also the contractors for the Forth Bridge undertaking.

Mr. Alfred Hubert, who, for twenty years, has practised as an architect and surveyor at Ipswich, recently died at the age of 38.

The new Claude Brown memorial reredos in St. Leonard's parish church, Hythe, East Kent, was unveiled on Tuesday week. It is Early English in character, and consists of an alabaster canopy, richly ornamented with the dogtooth. Beneath this is a bas-relief of Canadian marble representing the Entombment of the Saviour. The relief was executed by Mr. H. H. Armistead, R.A.; the canopy by Mr. Earp, of Kennington; and the design was furnished by Mr. G. E. Street, R.A., P.R.I.B.A. The cost has been over £1,000.

New sewerage works at Newmarket, Cambridge-shire, constructed from plans by Mr. J. F. Clark, C.E., were formally handed over to the local board as completed on Monday week.

A Bible Christian chapel was opened at Seal, Kent, on Wednesday week. It seats 150 persons, and cost £450. The builder was Mr. Boarse, of St. John's, Sevenoaks.

The harbour trustees of Maryport adopted last week a recommendation by Mr. Dobson, their engineer, to remove the light-house some 100ft. seawards from its present position.

At a meeting of the Wolverhampton Town Council on Monday the Mayor announced the receipt of a letter from a friend, offering to build a Public Art Gallery, to cost £5,000, provided that the town gave a suitable site, and that subscriptions amounting to £10,000 were first promised. The donor desired that a committee should be appointed to mature the plans, and added as a strict condition that his name should be kept secret. The Mayor expressed the hope that the required sum would be subscribed.

On Saturday week the Countess of Dartmouth laid the memorial-stone and new chancel of the parish-church of St. Mary, Lewisham, which has been practically recast with the exception of the lower part of the 15th-century tower, from the designs of Mr. Arthur W. Blomfield, M.A., of Montague-place, London. In the nave the flat ceiling has been replaced by an open roof, the area is being reslated, the gallery fronts lowered and opened out, and a new entrance provided. The cost of the chancel is between £2,000 and £3,000. The contractor is Mr. Parmenter, of Braintree, Essex.

A new village club-house at Benenden, Kent, was opened last week by Lord Cranbrook. It has been built from the designs of Mr. Devey, of London, and consists of a ground-floor of reading-room and amusement-room, and over these a committee-room, steward's apartments, and bedrooms for lodgers.

Extensive building operations have been and are in progress on the Dane Hill estate, Rungate. Mr. A. Pitts is the architect, and Mr. W. Martin, also of Rungate, the builder.

The extension of the Metropolitan District Railway from Mill-hill Park, Ealing, to Hounslow, is being rapidly pushed forward, and the embankment work has been carried as far as the King's Arms-lane, Hounslow, where a goods and luggage station will be built—while preparations are also being made for the terminus at Hounslow Heath. Mr. J. Wolfe Barry is the engineer. It is contemplated to obtain power next session to continue the line from Hounslow to Windsor.

The new public hall at Dersfourt, which has been built from the designs of Mr. Samuel Knight, of London, selected in competition, was formally opened on Wednesday week.

Our Office Table.

A YEAR having elapsed since the Clerkenwell vestry undertook the work of doing its own dusting, slopping, and watering, the works committee presented that body last week with the first annual report on the subject. The new system was commenced on the 19th of May, but contractors were engaged to a limited extent on day work till the 10th July. Since the 31st May, 5,570 loads of dust and 2,410 of street-sweepings have been removed; 5,837 chaldrons of ashes have been delivered to purchasers in 85 barges; 60 freights of street-sweepings and 14 of hard core have been removed from the wharf. The entire cost of buildings, plant, and preliminary expenses, incurred during the year, amounted to about £4,600, viz.:—Premium, £500; buildings and paving, and legal expenses, £1,993; horses, £1,155; vans and carts, £681; harness, £176; gas-engine and sundries, £155; towards meeting which £4,000 has been borrowed, repayable over five years. The expenditure for the year amounted to £5,385 9s. 2d., from which must be deducted receipts for ashes and breeze, £761 3s. 1d., and value of ashes and fodder on hand, £40, making a total of £501 3s. 1d., which, subtracted from the expenditure, leaves the net cost for the year £4,884 6s. 1d. The cost of the work during the preceding six years has averaged £3,947 9s. 3d.

It is rather difficult sometimes for an architect to know what a clergyman really does want in the way of style and construction, but there is no mistake about the requirements of the Bishop of Rochester. Speaking about the plans and requirements of new churches, in his primary charge last week, Bishop Thorold said:—"Why not try a Basilica, with a font big enough for immersion, and a pulpit in which the preacher can both move and think, and space in which people can see, hear, and worship? To all of which I would briefly reply, taking the last first: A fine red brick Basilica is the one thing of all others I wish to see. Who will build us one? No one regrets this new fashion of church building in fragments more than I; but it might be unfair for a bishop to interfere with local discretion." In deprecating a too-lavish expenditure under this head, his lordship suggested that it might be worth considering whether we have not had enough of Gothic churches with their difficult acoustics and expensive ornamentation.

It may perhaps interest some few of our readers to know that Miss Ethel Pierson (Mrs. F. E. Randell) was last week presented with a handsome bracelet by the members of Mr. D'Oyly Carte's "Pinafore and Sorcerer Opera Company," with which she was associated as *prima donna* for nearly three years. The bracelet is a massive gold one, and bears the following inscription:—"Presented to Miss Ethel Pierson (Mrs. F. E. Randell) as a mark of esteem by the ladies and gentlemen of 'H.M.S. Pinafore and Sorcerer Opera Company.' 'The fairest flower that ever blossomed.' 'Heaven bless Aline!'"

A PIECE of clever and skilful work was done at Elsecar parish-church on Friday last by Mr. Ball, the well-known steeple Jack of York Castle, Oldham. The spire has not been repaired since the building of the church in 1843, has been found to be out of repair, and the matter being placed in the hands of Mr. Ball, he commenced operations on Friday afternoon, by erecting eight ladders connected together, one at a time, as he rose from the churchyard to the weather-vane at the top of the spire, a feat of which Mr. Ball may feel justly proud, as the time occupied from start to finish was two hours and thirty minutes. We understand that, as the result of Mr. Ball's examination and report, a new lightning-conductor will be erected, and the spire thoroughly restored by him.

THE Trades Councils of London are providing themselves with evidence respecting the workmen's dwellings of the metropolis which seems to have an important political bearing. Circulars have been sent out to the trade committees in every district, which embody the following questions respecting the wants of the London workmen:—Are the present block dwellings suitable; are they built in convenient places; are they better or cheaper than the present house accommodation; should dwellings be pro-

vided in the suburbs, and, if so, what alteration in railway arrangements will be necessary? The questions have been asked with a view to providing the Artisans' Dwellings Committee of the House of Commons next session with information as to the views of the workmen themselves, which is regarded as essential before the new Act dealing with the question can be framed; and the questions given above were formulated by Mr. Broadhurst, M.P.

The Corporations of Glasgow and Dundee have decided to apply to Parliament for powers to supply the electric light to all places, including dwelling-houses, in each town. The extensive ship-building works of Messrs. J. Readhead & Co., at South Shields, are now being lighted by the "Brush" system, and Messrs. Leslie & Co., shipbuilders, Hebburn, are about applying the same system to their works. Last week experiments were made in the plate-mill department of the Consett Ironworks with the "Brush" system. If the present trial proves satisfactory, as it is fully expected it will, the company intend to extend its use throughout the whole of their plate-mills and forges. The Agricultural Hall, Islington, has been illuminated by the "Brush" system during the Food Exhibition. The lamps, of which there were twenty-four, were suspended from the galleries, and the power was derived from a fixed and a portable engine. The electric light in the British Museum has worked fairly well, but a few hitches have occurred.

A PROJECT has been set on foot for holding a Universal Exhibition in Rome in 1885-86. The support of numerous members of both Houses of the Italian Parliament having been obtained, Signor Orsini, secretary of the Central Committee of the Exhibition, has proceeded to London with letters from the Italian Ministers, and has constituted there a British Central Committee for the purpose of securing the participation of English exhibitors. The committee he has formed is composed among others of the Lord Mayor of London, Mr. Grenfell, Governor of the Bank of England; Messrs. Thomson Hankey, H. Palmer, W. Blake, J. Hambro, and A. Baring, directors of the Bank of England; and Baron Leopold de Rothschild. Committees will also be formed in Manchester, Birmingham, Leeds, and Liverpool.

AN Exhibition is to be held in Berlin next year of the "science and technology of health, and the saving of life." It is not international, strictly speaking, but foreign manufacturers are specially invited to send articles which are in any way connected with the subjects indicated by the title. Mr. D. Grove, of Friedrich-strasse 24, Berlin, S.W., will give all particulars to any of our readers who may be interested.

AN exhibition of models and plans of educational edifices is to be opened in Paris in the beginning of next February. For the best design of a lyceum the prize will be 10,000 francs; for the second best 5,000 francs, similarly with designs for a normal school; and various other prizes of less value are offered (for particulars of which see *Revue Industrielle*, Oct. 26).

THE Royal Commission on Technical Instruction, who have been in Paris for the last fortnight, have visited many of the elementary and secondary schools, as well as those for higher technical instruction, such as the Ecole Centrale and the Ecole des Mines. They have also spent two days at Chalons and at Rheims, and will leave Paris probably this morning for Le Creusot, Lyons, and St. Etienne. On their return to Paris they will proceed to Normandy and the manufacturing districts of the North of France. The secretary and a number of the Commission are now at Limoges, the principal seat of the porcelain manufacture. The Commissioners have everywhere met with the greatest readiness to give them all information.

CHIPS.

Messrs. F. and A. Wheelodon, architects, of Wolverhampton, have dissolved partnership.

West Free Church, Dundee, was reopened on Sunday week after refooring, reseating, and renovating, and the laying of a telephone from the pulpit to the bedside of a bedridden member of the congregation, 300ft. distance. The latter innovation is reported to be a success.

A new back is about to be built for Messrs. Lacon, in Norwich-street, East Dereham, from the designs of Mr. Brown, architect, of Norwich.

The memorial-stone of a New Jerusalem Church was laid in Waldegrave-road, Anerley, S.E., on Monday week. The building is Gothic in character, consisting of nave, 80ft. by 38ft., and chancel. Beneath the chapel proper is a schoolroom, and the angles of chief front are marked by turrets containing staircases of communication between chapel and schoolroom. The building has been designed and is being entirely carried out in Portland cement concrete by Mr. W. J. E. Henley, manager of the Concrete Building Company, Blackfriars-road, S.E. The total cost will be £3,000.

The Oxford Architectural Society visited on Saturday week the cathedral, where they were received by the Dean, who showed that the choir with its aisles, the transepts and towers, were of the latest period of Norman architecture, having been consecrated in 1180. The groined roof of choir was built early in the reign of Henry VI. Among the modern additions to the church furniture were the bishop's throne, designed by Sir Gilbert Scott, and executed in Italian walnut by Messrs. Farmer and Brindley, and the new reredos only placed in position a few weeks since; it is of red Damfries sandstone, with a central panel of Rosso antico, and was designed by Mr. G. F. Bodley.

The town council of Ipswich have raised the salary of the borough surveyor, Mr. Edward Buckingham, from £300 to £375 per annum. Mr. Buckingham was appointed in 1871, at a salary of £200, and since then, owing to the growth of the town, the number of men under his supervision has increased from 25 to about 100.

At the annual meeting of the Leek Art Class on Monday night it was announced that Mr. Joshua Nicholson, a silk manufacturer at Leek, would shortly erect a free library, picture gallery, and art museum. Mr. Nicholson, explaining his project, said its cost would not be less than £10,000, and he had arranged to contribute £500 annually until its maintenance was otherwise secured.

A new town clock at St. Michael's, Lewes, which has been constructed by Messrs. Gillett and Bland, of Croydon, is to be publicly started at noon on Tuesday next.

The town council of Bewdley has been negotiating with the gas company for the purchase of the company's undertaking and plant. The terms asked, £17 per £10 share, are, however, considered so high by the councillors that the proposals have been broken off.

Mr. G. E. Hawes, of Chapel Field, Norwich, has purchased the entire stock of iron standards manufactured by Mr. John Glendenning, late of Chalkhill Works, trading under the name of Colman and Glendenning, and is now offering "The Eastern Counties," "The Collegiate," "The County," and other desks at greatly reduced prices.

MEETINGS FOR THE ENSUING WEEK.

SATURDAY (TO-MORROW).—Opening of Chiswick School of Art. Dinner, 6 p.m.

MONDAY.—Royal Institute of British Architects. "Earthenware Pots (built into churches) which have been called Acoustic Vases." By G. M. Mills. 5 p.m.
Society of Arts. Cantor Lecture No. 1. 8 p.m.

TUESDAY.—Institution of Civil Engineers. "Forces and Strains of Recoil in the Elastic Gun Carriage." By H. J. Butter, M.I.C.E. 8 p.m.

WEDNESDAY.—Society of Arts.

FRIDAY.—Architectural Association. "The New Examination and What it Involves." By Prof. T. Roger Smith. 7.30 p.m.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE second Ordinary MEETING will be held on MONDAY, 21st inst., at 8 p.m., when a Paper by GORDON M. BILLS, Associate, on "Earthenware Pots built into churches which have been called Acoustic Vases," will be read. The next nomination of Candidates will take place on the 5th December.

J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.
9, Conduit-street, Hanover-square, London, W.

Trade News.

WAGES MOVEMENT.

PARIS.—As the carpenters' strike continues in Paris the masters are obtaining hands from abroad. On Thursday week no fewer than nine hundred men arrived from Belgium, two hundred and fifty from Switzerland, two hundred from England, and two hundred from Italy, who at once found work. On Friday a further detachment of three hundred reached Paris from Brussels, Antwerp, and Liège;

some two hundred are expected before the close of this week from Switzerland, and an equal number from the North of Spain. Thus a total of some two thousand foreign carpenters will next week be earning their bread in the French capital. In view of the number of strikes now existing in various trades, the French Academy of Moral and Political Science has offered a prize of five thousand francs for the best essay on "The Effects of Coalitions and Strikes." Competitors are directed to trace the movement in the rates of wages in trades from which strikes have been absent and in those in which they are of frequent occurrence. Valuable and interesting statistics may be anticipated.

GREAT STRIKE IN THE POTTERIES.—About two-thirds of the people engaged in the earthenware manufacture in the Staffordshire potteries struck work last Friday, in consequence of the employers refusing them an advance of wages. Nearly 30,000 men, women, and boys are out, and the struggle threatens to be prolonged. It is the first strike in the trade since 1836. Several of the large firms have arranged with their hands, who have not stopped work.

Epps's Cocoa.—Grateful and Comforting.—

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicate-y flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk. Only in Packets labelled—"James Epps and Co., Homoeopathic Chemist, London."—Make use of Epps's Chocolate Essence for afternoon use.

Lamplough's Pyretic Saline is refreshing most agreeable, and the preventive and curative of FEVERS, BILIOUSNESS, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute. See Medical Testimony.

Holloway's Ointment is not only fitted for healing sores, wounds, and relieving external ailments, but rubbed upon the abdomen it acts as a derivative, and thus displays the utmost salutary influence over stomachic disorders, derangements of the liver, irregularities of the bowels, and other intestine inconveniences which mar man's comfort.—ADVT.]

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—[ADVT.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates.

General Repairs and Alterations Executed: Experienced Workmen always in readiness, and sent to any part of the country.—[ADVT.]

BATH STONE.

BOX GROUND,

THE BEST FOR ALL EXTERNAL USE.

CORSHAM DOWN

CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.

(See trade advt. on p. XXIII.) ADVT.

TENDERS.

* * Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ASHBURN.—For the rebuilding of a bridge at Bagtor, for the Ashburnton district highway board:—
Joint and Eastbrook £39 15 0
Stevens accepted) 51 10 0

BARROW-IN-FURNESS.—For the construction of Salt-house high level intercepting sewer, for the Barrow Town Council:—

Watts, E., Barrow (accepted) ... £2,722 15 6
[Another tender was received for this work £3 lower than the above.]

BARROW-IN-FURNESS.—For the construction of a sewer from Hereford-street to the back street between Day and Leicester-streets, for the Barrow Town Council:—
M'Kenzie, F. (accepted).

BERMONDSEY, S.E.—For laying out the parish churchyard as a public garden, for the Bermondsey vestry:—
Maller (accepted) 21,179 0 0

BERMONDSEY, S.E.—For heating apparatus at the new town hall, for the vestry:—
Bacon and Co. (accepted) 275 0 0

BRICKENHEAD.—For erecting a shed for disinfecting vans:—
Snape, G., accepted at £31.

BATLEY.—For erection of Sunday schools to Zion Chapel, Branch-road, Batley. Mr. W. Hamstead, A.R.I.B.A., architect.

Accepted tenders.

Mason:—		
Goodall, C., Batley	...	£193 12 7
Joiner:—		
North, W., Batley	...	387 17 1
Plasterers:—		
Morton Bros., Batley	...	91 11 7
Plumber:—		
Senior, J. H., Batley	...	61 10 0
Thornton, J. M., Heckmondwike	...	61 15 3
		£1,000 9 6

BIRKENHEAD.—For the erection of a new set of gates and gate-piers at the Italian Lodge entrance to the Birkenhead Park:—

Stonework:—Gass, Amoss & Co. (accepted), £87; and ironwork, Jones and Williams (accepted), £30.

BLACKBURN.—For the erection of two dwelling houses in Cleaver street. Mr. J. Warde-Bulcock, A.R.I.B.A., architect.

Hacking, J. C. and A.	...	£520 19 0
Rowe, R.	...	315 0 0
Euston, R.	...	335 0 0
Kenyon and Moulding (accepted)	...	330 0 0

BROMSBURY, LONDON, N.W.—For the erection of stabling and coachhouse in the Elmware-road, Bromsbury, for Mr. J. Curzon. Mr. W. Graves, architect:—

Ward and Lambie (accepted).

CANNING TOWN, E.—For alterations to shop at Canning Town. Mr. Waite, Stair, architect:—

M-Lean	...	£1,510 0 0
Cawthorne	...	1,450 0 0
Hail	...	1,310 0 0
Oldwell	...	1,200 0 0
Clark	...	1,170 0 0

CARDIFF.—For kerbing, paving, and channelling the footways of Wellington, Edward, and Union-streets for the Corporation. Mr. Williams, M.I.C.E., borough engineer:—

Union-street:—

Pearson, J. C., Cardiff	...	£87 16 5
Smith and Pring, Cardiff	...	70 8 3
Rich and Harris, Cardiff (accepted)	...	65 4 10

Wellington street:—

Pearson, J. C., Cardiff	...	£110 8 8
Smith and Pring, Cardiff	...	100 5 14
Rich and Harris (accepted)	...	93 15 7

Edward-street:—

Pearson, J. C., Cardiff	...	£73 6 6
Smith and Pring, Cardiff	...	67 10 2
Rich and Harris, Cardiff (accepted)	...	64 4 10

CARDIFF.—For alterations and additions to Llanisher Villa, Cardiff, for Mr. Henry Garrett. Mr. W. D. Blesley, architect:—

Billiard room, terrace, porch, and stables:—

Shepton, S.	...	£1,750 0 0
Lock, F.	...	1,748 0 0
Jones, J.	...	1,665 10 1
Thain, W. (accepted)	...	1,645 0 0

CARDIFF.—For erection of new premises for the South Wales Fish and Poultry Company, 73, St. Mary's street, Cardiff. Mr. W. D. Blesley, architect:—

Thain, W., Cardiff	...	£1,670 0 0
Bird, C., Cardiff	...	1,650 0 0
Purnell and Fyfe, Cardiff	...	1,650 0 0
Gough, T., Cardiff	...	1,632 0 0
Gibson, R., Cardiff	...	1,628 0 0
Jones, J., Cardiff	...	1,580 0 0
Shepton, H., Cardiff	...	1,520 0 0
Jones Brothers, Cardiff	...	1,500 0 0
Howard, F., Cardiff	...	1,285 0 0
Roberts, E., Cardiff	...	1,225 0 0

CHARING CROSS.—For new medical schools, for the Charing Cross Hospital, Chancery street, W.C. Mr. J. J. Thompson, A.R.I.B.A., architect:—

For blinds, Guyan and Son, Carburton (accepted).

* Accepted.

GRANTHAM.—For the formation of a curved embankment and railway for the North Junction at Barkst near Grantham, for the directors of the Great Northern Railway Company:—

Baker and Firkbank, Lincoln (accepted).

HASTINGS.—For the construction of three oak timber groynes, one opposite Carlisle villa, one opposite Breads-place, and one opposite Beach-terrace, Hastings:—

Austin and Dibley, Hastings	...	£1,350 0 0
Winer, F., Hastings (accepted)	...	1,145 0 0

HALIFAX.—For the erection and completion of a shed, for Messrs. Whiteley, Holden, and Co., hydraulic engineers. Mr. J. Willey, 30, Southgate, architect. Quantities by the architect:—

Excavator, mason, and bricklayer:—

Spencers Bros., Halifax	...	£195 0 0
Pickles, J., Halifax	...	191 0 0
Hopkinson, W. and Sons, Halifax	...	187 0 0
Calpan, N. and Son, Halifax	...	185 0 0
Parkinson, R., Halifax	...	164 0 0
Furness, H., Halifax	...	163 14 0
Kitchen, J., and Wild, J., Halifax	...	157 0 0
Turner, T., and Bros., Halifax	...	156 10 0
Forster, A., Halifax	...	150 16 0
Wilson, J. W. and Son, Halifax	...	150 0 0
Riley and Robinson, Halifax	...	140 0 0
Naylor, E., Halifax	...	139 0 0
Simpson, G., Sowerby Bridge	...	137 15 6

Carpenter and joiner:—

Holden, T., Halifax	...	110 0 0
Suzellie, S., Halifax	...	106 10 0
Boocock, E. H., Halifax	...	106 10 0
Townsend, G., Halifax	...	100 0 0
Noble, W. H., Halifax	...	98 10 6
Farnell, J., Halifax	...	96 0 0
Fleming, J., Halifax	...	95 0 0
Byson, J. and Son, Halifax	...	91 10 0
Greenwood, S., Halifax	...	92 10 0
Turner, J., Halifax	...	90 0 0
Holstead, A. and Son, Halifax	...	90 0 0
Tuley, T., Halifax	...	89 10 0
Yates, L., Halifax	...	86 12 11
Crossland, J. and Son, Halifax	...	80 10 0

Slater and plasterer:—

Wadsworth, H., Halifax	...	65 0 0
Burgett, S. and Son, Halifax	...	58 0 0
Taylor, J., Halifax	...	52 0 0
Pickles, S. and Son, Halifax	...	51 0 0
Taylor, S., Halifax	...	50 8 0
Wadsworth, W. H., Halifax	...	50 0 0
Bancroft and Taylor, Halifax	...	45 0 0

Plumber and glazier:—

Barker, T., Halifax	...	43 0 0
Walshaw, C. A., Halifax	...	40 14 3
Scruton, J., Halifax	...	36 10 8
Akro, D. W., Halifax	...	36 0 0
Futh, J., Halifax	...	35 5 2
Architect's estimate	...	325 0 0

* Accepted.

HALIFAX.—For erection of a shed to cover 900 yards super., and cellaring (part fire-proof) co-extensive therewith, in Halifax. Mr. J. Farrar, Crossley-buildings, 20, Northgate, Halifax, architect:—

Mason's work:—

Jenkinson, H., Halifax	...	£950 0 0
------------------------	-----	----------

Ironfounder:—

Berry, J., Halifax	...	613 6 8
--------------------	-----	---------

Joiner:—

Halliday, J., Halifax	...	380 0 0
-----------------------	-----	---------

Slater and plasterer:—

Blackburn, A. S., Halifax	...	192 0 0
---------------------------	-----	---------

Plumber and glazier:—

Firth, S. and Son, Halifax	...	179 10 0
----------------------------	-----	----------

HASLING.—For construction of a large oak timber groyne at the battery, Rock-a-Dore, Hastings:—

Austin and Dibley, Hastings	...	£2,400 0 0
Winer, F., Hastings (accepted)	...	2,350 0 0

HATFIELD, HERTS.—For building a lock-up at Hatfield. Mr. Urban A. Smith, C.E., county surveyor, Hatfield:—

Twelvevrees, E.	...	£7,585 0 0
Hunt, T.	...	6,775 0 0
Gibbons and Co.	...	6,597 0 0
Angood, J.	...	6,600 0 0
Glassecock, J. L.	...	6,233 0 0
Willmott and Son	...	6,196 0 0
Seaks and Norris	...	6,175 0 0
Beale, W. J.	...	5,977 0 0
Wade and Eley (accepted)	...	5,870 0 0

HEDDERSFORD.—For pipes in connection with the new water supply for the town council:—

Roberts, J. and S. (accepted)	...	5in. and 6in. pipes, £1 16s. 3d. per ton; 4in. pipes, £1 17s. 6d. per ton, delivered at Hereford.
-------------------------------	-----	---

HUNTINGDON.—For additions of a store-room, disinfecting room, and office to the barracks:—

Rowe, J., Huntingdon	...	£454 0 0
Markham & Mason, Godmanchester	...	449 0 0
Balmer, Huntingdon	...	449 0 0
Howard, J. H., Huntingdon	...	420 0 0
Rowe, W., Huntingdon	...	410 0 0
Lord, C., Huntingdon (accepted)	...	405 0 0

IPSWICH.—For extension of laundry, and building a drying-room at St. Peter's Workhouse, for the Ipswich board of guardians. Mr. H. M. Byton, architect:—

Barford and Perkins (recommended for adoption), £200.	...	
---	-----	--

KILBURN, N.W.—For the erection of stabling at Kilburn, for Mr. J. Griffiths. Mr. W. Graves, architect:—

Ward and Lambie (accepted).	...	
-----------------------------	-----	--

KING'S NORRIS, BIRMINGHAM.—For extension of the sewer in Wake Green-road, including manholes, ventilators, &c., in Mossley District, for the King's Norton rural sanitary authority. Messrs. G. B. Nicolls and Son, C.E., engineers, Imperial Chambers, A.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 25, 1881.

THE TEWKESBURY ABBEY CHURCH RESTORATION.

THE indefatigable Society for the Protection of Ancient Buildings is airing another grievance. Its secretary recently wrote to the *Times*, calling attention to a rumour that a proposal was about to be made to "destroy the fine west window" of that well-known church, Tewkesbury Abbey, and inclosing a report of a competent member of the Society upon the state of the western archway and window. The conclusions arrived at are: that the stonework is in a good state of preservation, and that the restoration is quite unnecessary, and would lead to the effacement of another interesting portion of the Abbey, an ancient fabric which has already received irreparable damage at the hands of the "restorers" of the present day. This letter proved to be the commencement of a controversy between the vicar of Tewkesbury, Canon Venables, Sir Edmund Beckett, and other disputants for and against the contemplated restoration. The reader will fail to gather any very distinct idea from any of the letters as to what it is really intended to do at Tewkesbury, and, in fact, the age of the present west window has become the primary question of quarrel. The great inclosing arch has seven orders, one of which was discovered buried in the wall by the late Sir Gilbert Scott during the recent restoration, and the present window is supposed to occupy the position of several small windows of Norman date. The professional adviser of the society states, with regard to this Perpendicular window, "that the main lines of the tracery still remain, and that the date 1686, which is cut on the shield and tablet on the existing window, refers to a general repair and alteration of the tracery rather than to a complete rebuilding of the whole." The date, moreover (1686), is a stubborn fact, and the opinion is borne out by a well-attested fact that the window was blown in in the year 1661. According to the Society's report, the inserted window in the great Norman western arch is only one of a series of changes made at various architectural periods. The archway was, it is asserted, always filled up by a wall as it still is, and evidence of this is adduced by the writer, such as that the innermost shaft of the seven engaged stone shafts of the archway "is worked in the same stone as the start of the wall," and the remains of part of the old west Norman doorway seen inside, and which it is said rose higher than the sill of the present window. The writer does not tell us what the Norman windows (if any) were like, but mentions the traces of a Decorated window in the early part of the 14th century, when the Norman doorway was blocked up, the sill of the inserted window cutting into its arch. At this time the wall is said to have been thickened on the outside 16in., which wall concealed the inner shaft. Various traces of this remain; the inner arch, the outer member of outer arch, the jambs, and part of mullions. The detail is described to be of pure Early Decorated design, and the report goes on to say, "It appears very improbable that the builders during the Perpendicular period, or in the year 1686, would have used these Decorated mouldings if they had started afresh making an entirely new window, and had no parts of an earlier one into which the new work had to be

fitted." The next change was the alteration of the Decorated into a Perpendicular window, the main lines of which are said to remain. It is at least pretty conclusive that the date 1686 refers to a general repair and alteration, rather than a rebuilding of the whole, and the semi-Classic corbels introduced confirm this view. As everyone who has seen this fine west front knows, the present window is of Late Perpendicular design, and of seven lights. The stonework is in good repair, the mouldings being sharp. The late Sir Gilbert Scott, adds the writer of the report, expressed a very strong opinion that it should be preserved, and it is stated further that the Restoration Committee are at present divided on the subject.

Such is the position of the question. It may be inferred, from the letter of Mr. Robeson, the vicar of Tewkesbury, that the question of the restoration of the window has been before the Committee, who have entertained doubts about it, and the report of the Society is welcomed as a contribution towards the general knowledge of the subject. But the Society was precipitate. From our own personal inquiries, we find the majority of the committee are opposed to the restoration of the window; and that in this, as in some other instances, the officers of the Society have allowed their valour to outrun their discretion. The Committee have not instructed Mr. John O. Scott, their architect, to prepare any design, and that gentleman, we believe we are right in saying, has never proposed that the west window should be restored, though he has recommended that good painted glass should be put in. The whole dispute has sprung out of a mere rumour of "some possibility of a proposal being made to destroy it." The Society has found a champion in Canon Venables, who, rather amusingly adds his protest against an attempt which has not yet even an existence. He refers to "this fresh attempt to reduce our grand historical buildings to an ideal standard of purity of style by the effacement of essential features, which, however much we may sometimes regret their introduction, have become part of the history of the fabric." The well-used argument of the Society, that architecture was once a living art, and was perpetually receiving additions and alterations in the successive styles of the day, is again dragged in, without any notice of the fact that it is an argument which may be used to support the modern restorationist as well. Why should 19th-century architects be denounced as destroyers who have only been doing more thoroughly what the 16th and 17th century restorers did ignorantly? Canon Venables refers incidentally to St. Alban's, which is hardly an analogous case. At St. Alban's Abbey a small outlay would have been sufficient, probably, to restore the west front from existing data; the stonework was not decayed to any extent. It is perfectly true, nevertheless, that any restoration of Tewkesbury must be chiefly conjectural, and on this ground to a large extent destructive, and every architect and archaeologist would deplore the destruction or serious alteration of so grand and unique a western front. With a good deal of the Canon's letter we agree in the abstract, but we fail to see how they apply to a restoration which is not yet even in contemplation. The window is not threatened, it is in a good state of preservation; the date is known to be that of repairs to the original Perpendicular window, and we can scarcely think the restoration committee will commit themselves to the introduction of a window simply for the sake of its being new, however much it may appear to harmonise with the style of the interior. So far, all is speculation and surmise. With the doubt

expressed by one correspondent whether the opening was ever intended by the original architect to be a window, we have little to do. Whatever the intention of the builder of the great arch may have been, no modern restorer would venture to tamper with a feature which has ever marked Tewkesbury as a grand and unique specimen of English Norman architecture. Canon Venables' letter has brought Sir Edmund Beckett into the arena. With characteristic fervour, and not a little common sense, Sir Edmund asks: "What is the real condition of the present west window? Would a restoration of it be practically a rebuilding, mostly in new stone? A good measure of that is the estimate." To us this is the real point of the whole question. If a "restoration" amounts to rebuilding the window in new stone, the committee have a reason for asking their architect to prepare a design in accordance with the old front. Facts prove that such a state of things does not exist—that the window needs little or no repair.

Enough has been said to show the nature of this uncalled-for agitation about a restoration not even contemplated. No doubt can be entertained that a great deal of money has been wasted on unnecessary restorations—we would rather call them reconstructions—of late years, though no one will be disposed to cavil at what Sir Gilbert Scott did at Tewkesbury, a description of which will be found in the *BUILDING NEWS* of September 26th, 1879, and illustrations on May 11, 1877, and August 12, 1881, p. 195. Nor can it be denied that to substitute an imitation of something older; for Late work, to insert, for example, a Norman window under the great arch at Tewkesbury abbey-church, would be a very stupid and unnecessary proceeding, especially when the Perpendicular window is in a good state of preservation. The window now existing is declared by some to be a specimen of Late Perpendicular work unworthy of respect, while the Society for the Protection of Ancient Buildings declares it to be of good design, and that the mayor and churchwardens who have their names inscribed with the date 1686, simply appropriated the remains of the older windows. To pull to pieces a solid and substantial window, as this is said to be, just to gratify the taste of a few, and when other repairs are more necessary, would be exceeding the duties of those entrusted with the care of the fabric. The whole question ought to rest on the evidence of the condition of the window, and we have every confidence in the discretion of a committee guided by the care and caution of so conservative a restorer as Mr. John O. Scott, into whose hands the work of restoration has recently fallen. On the other hand, the Society, by rushing into print and sounding a false alarm, has, to a certain extent, and not for the first time, led people into the belief that something of a most destructive kind was going to be done. The zeal of its officials has unnecessarily exceeded their care to acquaint themselves with the real facts of the case on which they base their appeal; and the readiness of their "competent member" to report on another architect's work seems at the best hasty and inopportune.

THE FEMALE SCHOOL OF ART.

THE exhibition of drawings, held at the Female School of Art, 43, Queen's-square, Bloomsbury, affords an excellent proof of the success of this establishment. The course of instruction in this school, which is in connection with the Science and Art Department, comprises the usual branches of geometrical drawing and perspective; freehand drawing from the flat and from the round; shading from the same; model

drawing; figure drawing, from the antique and from the life; modelling in clay and wax; painting in water-colours, tempera, fresco, and oil; original designs for decoration and manufactures, &c. The Queen's Scholarship, of the value of £30 per annum, tenable for one or two years, has been won by Constance Wood, for a chalk drawing from the antique. The Venus is a fair specimen of this lady's skill in figure drawing. Mary Elizabeth Harding takes the Clothworkers' Scholarship of £20 for some excellent work, and the Gilchrist Scholarship of £50 falls to Ethel Chapman Nisbet, and O. A. Bodé. Mary E. Harding wins the Queen's gold medal and Florence Reason a National silver medal. The gold medal is for a group of fruit—melons and grapes in a vase, from Nature. The grouping and colour are both excellent. Florence Reason's truthful sketches of poppies and yellow roses display a charming appreciation of flowers, and the delicacy of handling and execution satisfy the most exacting. Ethel Chapman Nisbet, in a set of five water-colour studies, has shown herself also an adept in manipulative skill with the brush, the poppies and peonies, and the shells being beautifully drawn; and in the same branch of art we must award praise to Mary Emily Carter's *peppa-nuts*, lemons, and pomegranates—both of which ladies win National silver medals. Norah Waugh well deserves the bronze medal for her "Gladiator," from the antique, in oil; and the same distinction is conferred on Rose Ethel Welby, for a group in water-colour of daisies and buttercups, delicately drawn and coloured; and to Edith Harris for a white geranium, charmingly true to nature. These are the chief prize drawings; but we glance also at the series of heads in oil on the end screen. One of a female is full of rich harmony in colour, with a golden-toned background, admirable in drawing and expression, calls for mention; and another of an old man's head, bold and truthful: both are from nature. The studies in oil of M. E. Harding, F. Reason, and Christmas are admirable also. The still-life groups in oil are, with the exception of the gold-medal picture, of less merit. Lillian Abraham is another young lady who has made her mark as a water colourist; while Kate Richard's geraniums, grapes, and apples are inimitable specimens of skill in fruit-painting. "A French Peasant Girl," by Florence Reason, and several other studies of the same subject must be noticed. Emily Stone's sunflowers are vigorous and cleverly drawn. Of prize monochrome studies Norah Waugh's "Wrestlers," and Ethel Chapman Nisbet's ornament, a frieze from the cast, shaded in oil, deserve special commendation.

Among the chalk studies from the antique, of which there are several, we place in the foremost rank Florence Reason's fighting gladiators; after which the studies by Misses Ashton and Harding, and the heads from the life by Misses Lovell, Payne, and C. Wood must be mentioned.

The contributions of students in the upper rooms are even more interesting and instructive, as showing the practical work of the school. These include water-colour, sepia, and chalk drawings. We meet here with original designs for ornament: Jane Cooper's design for fireplace—an arrangement of flowers and conventional panels and borders, is worthy to be noted for some boldness and spirit; and another original design shows a conventional arrangement of buttercups and cinquefoil for door-plates, by Edith Robinson, who receives a bronze medal. The designs for door-plates, by Marion Henn and Agnes Lee, are of merit; and Dora Crittenden is another lady artist who has shown undoubted skill in folial arrangements. The vacation prizes awarded are several. The studies of flowers by Rose E. Welby, Ellen Prowse, and Louisa

Williams are thoughtful transcripts of nature; and we particularly call the attention to the water-colour studies of skies, by Otilie H. Bodé and E. Deane. These are freely executed in simple colour from nature. E. Prowse and E. Flack also obtain prizes for objects sketched in colour. Even more noteworthy of the kind of instruction afforded in this school are the admirable series of "tit-bits," to use an artist's phrase, called "artist memoranda." Ethel C. Nisbet, a young lady who has made her mark in other branches, has here a delightful series of sketches of buildings, foliage, and other accessories executed in a masterly manner, and we must speak very highly also of the studies, contributed by Mary Harding, Edith Ellison, Rose E. Welby, and O. H. Bodé, and others. This kind of analytical study of the landscape is of great service to the student. One of the objects sketched in colour is a Gothic doorway, and the accuracy and precision with which it is executed is worthy of all praise. O. H. Bodé's pencil sketches are feelingly drawn. We notice in passing an Egyptian border design for plates of some boldness.

The Gilchrist prizes for advanced ornament are awarded to Edith Rowe for some clever tile and dado patterns, and to Agnes Lee, for frieze ornament, and the prize for elementary figure drawing to Marion Henn. Misses Flockton and Forster are able exhibitors in sepia ornament from the cast, and the heads from the antique in chalk, by Misses Rushton, Flockton, Whiteher, &c., call for a passing tribute.

In model drawings, the Baroness Burdett-Coutts scholarship of £40 is awarded to Dora Crittenden; Alice Barclay obtains a prize for model, and the prizes for freehand go to M. Cathcart and Dora Crittenden. A vase and cylinder, shaded in chalk, is the subject of the Baroness Burdett Coutts' prize, and we see other clever drawings evincing an accurate knowledge of perspective, light and shade in this department. The Female School of Art by these prizes furthers the principles of a solid art training, which has been too long neglected in the instruction of drawing among girls. Here we find proof that geometrical drawing and perspective drawing from the round, including shading, have not been overlooked. Prizes have been awarded also for modelling, and we find Henrietta Marcus is the successful student for modelling a hand from nature. There are also drawings for a design for a cameo brooch, for which F. Reason, Edith Ellison, and M. E. Harding have carried away prizes. We must not forget to notice the very creditable specimens of wood-carving by female students of the National School of Wood-carving. Ellen Hind obtains a prize for some frames, and this branch of art work has been ably pursued by several ladies. The exhibition amply justifies the reputation earned by this school for the thoroughness of its teaching under the skilful superintendence of Miss Gann, the lady director. The national and local scholarships, such as the Gilchrist, the Clothworkers', the Queen's Gold Medal, and the other prizes open to students are high enough to encourage and develop the best female talent for art, and hence the contributions are all above the average standard.

LONDON SQUARES AND OPEN SPACES.

WE take the opportunity, every now and then, of advocating the cause of public improvements in this great city, and hinting occasionally at what, as we think, might well be done towards the rendering it more healthful and pleasant than it is. These so-needed improvements are, indeed, many in number, and must needs be added to all but indefinitely; but there is one

which, as we have always thought, precedes others, and that is the increase and improvement of our London Squares and open spaces, and grass and tree planted spots of ground. These open spaces are, as it is, but comparatively few in number, and are not a little irregular, and wasteful in their arrangements and setting out, and it is not a little grievous to note in the suburbs of London, and all round it, how little provision has been made for adding to these open and grass covered squares. In the district to which we here more particularly refer, and the one which has most closely come under personal observation, there is a whole town, we had all but said, where not a single "square," whether new or old, is to be found. Whole lines, miles we may say, of quite straight streets of small houses have been built up, and are at this moment in course of building, where a square, or open space, has not so much as been thought of. Surely this is a mistake, and must concern not the special district only, but the whole of this vast city, for the inner and dense parts of it must feel the influence of its so close and pent up surroundings.

In glancing at a map of London, whether old or new, it will be seen how out of sheer accident it is that a square shows itself. At times they are comparatively close together, as are Portman-square and Manchester-square, and sometimes they are fully a mile apart, as in the East-end of London and in Southwark. Here and there is one of goodly size, as Lincoln's Inn-fields, and at others so small and crowded up is the square as to be all but unnoticeable—all simply showing how accidental has been the fact of there having been any thought taken about them. But better late than never, for there are not a few spots where even now, and as it is, a square might be formed, and a bright plot of grass-covered ground made to appear where now all is dull and dismal enough. But without waiting for this, may not, as has been suggested, the present squares of London be made more useful than they are now, and opened to the public and made more accessible and pleasanter every way. We can but think they may be, and it is towards this doubtless that the suggestion has been made that the large square of Lincoln's Inn-fields should be thrown open to the public. It would be difficult to see how a better beginning could be made, or a better example set, and there must be some special interest in this particular square which has thus caused it to be selected as the one to begin with, and thus to test the utility and advantages of the proposed opening of the London squares. Lincoln's Inn-fields is indeed a notable place, and has been in its day the theatre of some remarkable events, and the place of abode of some remarkable men. It was first laid out in 1619. Newcastle House, at the corner of Great Queen-street, was the residence of the Lord Chancellors Somers, Cowper, and Harcourt, and of the Duke of Newcastle. This house is on the west side of the square or fields, together with Lindsey House, the work of Inigo Jones, and a good one it is and right carefully designed, as all his work in London is. On the east side is Lincoln's Inn Hall by Philip Hardwick. The Royal College of Surgeons is on the south side, as formerly was Sir William Davenant's theatre. On the north side is the museum formed by the architect, Sir John Soane; so that all round the grass covered plot in the centre are to be seen some historic memorials and notable structures. It may be mentioned, too, that in the centre of the Fields was beheaded, in the reign of Charles II., on the 21st of July, 1688, Lord William Russell, a remarkable man, in very many ways, and one whose "history" is noteworthy. Thus, in the proposition to open the "Fields" to the public, there will be found in them much more than the grass and tree-covered ground itself now

confined to so few living in the square itself, or its more immediate neighbourhood. There will be found as well, many things of interest which would otherwise pass, may be, without note, but which can but add to its interest with the public at large.

But it is not this alone which makes Lincoln's Inn-fields noteworthy, and a fitting place in which to begin the opening of the London squares to the general public, or in other words, the making a right of way through them. It is one of the largest, if not the largest of the green spots of London, and might be made yet larger without detriment to the surrounding roadway. A careful examination of a good plan of the ground is necessary to see this, and we would call attention to it in the hope of its being attended to elsewhere, for in not a few of the London squares, *e.g.*, St. James's-square, the grass, and in some cases, the flower-planted ground, bears no proportion to the whole space or square inclosed by the surrounding houses; while the roadway is altogether, and quite unnecessarily broad, and out of all proportion to the traffic requirements of the locality. We name this the more especially, for it needs but a glance at any coloured map of this huge London City to see how much is lost to cheerfulness and comfort, and may be *health*, by the merely accidental and haphazard way in which these matters, and the like of them, have been worked out. In this special case of Lincoln's Inn-fields it will be noticed that running north and south are Gate-street and Portsmouth-street, and which, though somewhat narrow, are amply wide enough to take the whole traffic as it is, and hence the green and grass-covered plot might well be made to fall in with the lines of these streets, and thus to be so much the larger, and the more sightly.

And this applies equally to the other sides of the square, so that the inclosed grass and tree-covered space in the centre of it might be very greatly *added to*, without difficulty, and most surely the *larger* this is the better; an addition, indeed, we may fairly say, to the *lungs* of London. There is, as we have said, but may well repeat it, hardly a square in London wherein this increase in the area of the inclosed grass and tree-covered space might not be greatly added to without at all interfering with the carriage roadway around it. Portman square, to name but one other, is a large one, and the centre only is occupied with a small oval-shaped garden, so that fully *one-half* of the space is lost. The streets running north and south, and east and west, are fully equal, perhaps more than equal, to the road traffic, and were but the garden brought into a line with these, so much the larger and pleasanter would this garden be. This subject might well be brought to the notice of the authorities all over wide London, where there now exist any "Squares," or where any improvement is at all possible. There is need but to hint here at the number of comparatively quiet London streets in which some signs of nature's work in this way might well find a place, but which are, as things go, so full of desolation. Here and there it is true, by mere accident, this has been done, and a goodly row of trees are to be seen; but such are, it need not be said, but too rare.

It is somewhat curious to note that there is no "square" within the bounds of the "City" proper, the really oldest part of this huge metropolis, with the exception, if it can be so called, of Moorfields in the north of it, and touching its very wall, those of Finsbury-square, the Artillery Grounds, and the Charter House Grounds and Square being to the north of it, though quite close to it. Not to travel beyond the immediate subject of London squares we may perhaps, in passing, express some regret at the poor use that has been made, or is making, of the Thames

Embankment as a place not alone for traffic, but for long and regular lengths of green and grass-covered and tree-growing spaces or squares. It extends all but from Blackfriars-bridge to Chelsea-bridge, and would seem to have offered an opportunity hardly to be surpassed. What the old Assyrian, in his barbaric days, would have done with it, who will venture to imagine? With the great river on one side, and with the great city on the other—a city, as we are often reminded, of "palaces"—what would he not have done with these elements of greatness and architectural and natural display? A very hard and difficult art problem presents itself here, from whatever point of view looked at, for Nature herself must needs adapt her forms and rough grouping to the regularity of architectural requirements, or the architecture must needs be made to bend to them.

Much else there is which calls for note here on this subject of the squares and green spots in the midst of London. There is, however, one special phase of it which may well be made careful note of. It is that of the but too excessive care and attention which would seem to be given to the work which Dame Nature does so well, though roughly. The magnificent luxuriance always to be observed in utterly neglected and out of the common way spots of ground contrasts not a little strangely and instructively with the careful prunings and cuttings, and orderly arrangements of the well-kept and dainty garden and fashionable square. Most surely it is quite possible to do too much. Lincoln's Inn-square has indeed, to some extent, escaped this, for a goodly expanse of fresh-looking grass is visible, and the trees show signs of unheeded growth and of natural forms; but this is not always so, as many must needs have observed. These squares and gardens might well, too, be made of interest in a botanical sense, and left so far to nature as to show how infinitely varied are the forms produced even in the very same species of plant, whether tall tree or ground-plant, or humble grass-blade. Educationally, then, how much is there here? C. B. A.

"A BEAM FROM ST. MARK'S."

SO much has of late been written about ill-fated St. Mark's, that it may seem almost superfluous to add more. In what has been published here, however, I have not yet observed that the special feature, which I propose to discuss, has been alluded to; and moreover, my subject, rather than relating specially to St. Mark's, has been suggested by it.

It is possible that some few careful observers of the west front of St. Mark's will have remarked that the arches of the upper arcade are not strictly vertical, but inclined gently towards the beholder. When Meduna had in view the destruction of the west front in a manner similar to that in which the south and north have been destroyed, one of the first things he did was to remove the oggee crowning from the southernmost of the upper arches, asserting the inclination of this arch to be good cause for the proposed restoration.

I believe that since I was in Venice this ornament has been replaced, but the church was for so long a time to be seen deprived of it, that the blank cannot fail to have been noticed. I may say here merely in passing, that this interference was fraught with most unfortunate consequences to the old mosaic of the archivolt, much of which fell out when once exposed.

Now, we all know how the Northern picturesque builders of timber-framed constructions, made the gables in their streets to overhang. Often, no doubt, this was the result of settlement, often of careless build-

ing—to which the kind of construction might easily lend itself—but just as often of intention. From whatever cause, the effect produced is a great one. Let us number the upper arches of St. Mark's, (1), (2), (3), (4), (5), from our left as we face it, and bearing in mind, that we have to deal with Byzantine circular arches, capped by Gothic ogges; then the forward inclinations of the Byzantine arches are respectively, 15, 8, 7, 11, 10 centimetres, these inclinations being severally determined by suspending a plumb-line from the head of an arch, and taking the distance the plummet hangs forward in front of a line from springing to springing. Note, however, in these measurements that arch (5) has been—I cannot say how much—renewed, and its inclination must not therefore be entirely depended upon, although it cannot but be something approaching what it originally was.

Thus we see that the centre arch is inclined slightly to the beholder, and those flanking it a little more so. And here I must remind the reader of what Mr. Street has pointed out to us—that the whole front is set out in a curved line, recessed 25 centimetres in the centre, and I would ask him for a moment to consider the effect of this feature, combined with that of the inclination, imagining himself standing right in front of the centre of the building. Each side, as it were, is turning and nodding towards him. But do not let it be thought that I am here hastily about to make the rash assertion, that I believe this inclination to have been the result of deliberate intention on the part of the old builders. I do not think that anyone who has really entered into a study of St. Mark's will doubt that the feature noted by Mr. Street is so, and I certainly do suggest that this one under consideration may, perhaps, not be quite so much of the result of settlement as Sig. Meduna would have us believe. I have called attention to it, as well as for its own sake as that it forms a fitting introduction to the further consideration of some cases, which, while they may to some extent reflect back upon St. Mark's, will certainly prove to the most incredulous that the later Venetian builders (15th century) were, in their refined stone constructions, alive to the effect which could be produced by the studied inclinations of the upper members of their buildings.

Fig. 1 is an outline—lettered for reference—

of the upper part of the Porta della Carta, which I need hardly describe as the great entrance to the Ducal palace. It was erected under the Doge Foscari by Giovanni and Bartolomeo Bons, 1439-1441, and is therefore somewhat later than the last Gothic additions to St. Mark's. Gothic had expired in Venice by 1480. It is, then, one of the erections of its latest times; but despite this, and the fact that it is a composition which has met with some abuse, I must confess much liking for it. That the brothers Bons

were artists who believed that some effect was to be obtained by inclination, will appear from the measurements I am about to give.

The height of *a* from the ground is 12 metres or 39ft. 4in.

ab = 1.29m. (or 4ft. 1in.) and inclines outwards 12 millimetres.

bc = 1.03m. (or 3ft. 4in.) and inclines outwards 12 millimetres.

cd = 1.70m. (or 5ft. 7in.) and inclines outwards 83 millimetres.

i.e., the whole projection of *d* is a little more than 1 in. in a height of 13ft., and the gable in section takes the form I have shown by the exaggerated line *ABCD*. The finial which forms a pedestal for the statue of justice barely continues the inclination of *CB* (on account of its swelling foliage, no further inclination is necessary), so that the lateral mouldings at its top are inclined 27 millimetres in a depth of 470, or, roughly, 1 in 18; that is, if we could stand about 305 yards down the piazza away from the porta, and look at these mouldings, the visual beam would be in one line with the line of them, thus (see Fig. 2). This may, perhaps, serve

FIG. 2.

as a practical illustration of the amount of inclination.

But we have yet to consider the most subtle part of the arrangement. The medallion over the arch head contains the figure of St. Mark, and thus vies with the crowning Justice in forming the feature to which all else leads. Its outer diameter = 1.55m. (5ft.). Now note: it is placed between *bc* and *cd*; *bc* is inclined forwards about 1 in a height of 86; *cd* about 1 in 13; and the medallion 32 millimetres in a diameter of 1.55m., or, roughly, 1 in 48; that is, its inclination is intermediate between those of *bc* and *cd*, and it therefore takes the position I have indicated by the line *F.G.* in Fig. 1. Such arrangement speaks for itself, and with regard, at least, to the Porta della Carta takes the matter out of the reach of dispute. But to show how all is in harmony, I go on to notice the lateral pinnacles or needles. That lettered *f* seems to have suffered some restoration; but *h*, the small one on the right, has its axis leaning forward 30 millimetres in a height of 1.26m., (this latter measurement taken from the top of the little gablets to the underside of the finial). The centre pinnacle *g*, measured in the same way, has its axis inclined 70 millimetres in a height of 2.28m. I regret that the difficulty experienced in taking the measurements prevents me giving corresponding ones of the pinnacles flanking the gable on the other side. In now passing on from the Porta della Carta, it will suffice to state that the lower part of the structure and the wall rising up behind it are strictly vertical.

Let us now turn to the consideration of the gateway of the Scuola San Giovanni Evangelista. This Scuola was a corporation founded about 1350, by workmen of all trades, and the first building seems to have been completed in 1405, but about 1480, or later, large additions were made. A fine staircase was added, leading to a hall where once hung some of the best Bellinis and Carpaccios now in the Academy, and at the entrance to the cortile was crested a highly decorated central doorway, surmounted by a circular pediment, and on

each side of it, lateral pedimented windows, the whole in the manner of the earliest Venetian Renaissance.

I leave the accompanying outline to speak for itself. (Fig. 3.)

Scuola San Giovanni had the ill fortune to undergo some restoration in the year 1731; but, from what Mr. Ruskin says of its state, when he wrote in 1877, this does not seem to have done it such injury as one would suspect from any extensive repairs; but, especially, from any such carried out at that date. Moreover, it is highly probable, that if actually pulled down by the despicable builders of that century, who seemed to have little better aim than precision, the pediment would have been set up strictly vertical. Hence, as we see it, it appears a good example, without doubt, of the point we are considering. It is, then, with much sadness, I have to say that no one will again see it as Mr. Ruskin describes it. It is in the hands of the restorer, and it is but small comfort to be told that there is a chance of the old marbles being replaced without being scraped. Although a digression, I may here also state that the Church of S. Giovanni, standing in the same cortile with the Scuola, has the remnants of a Gothic apse. Only a few weeks ago, I had a letter from Venice, bearing the tidings that this had just been "whitewashed." Can we wonder at the way they have treated St. Mark's, which, truly, I had rather have seen whitewashed than in its present state—whitemarbled!

Returning now to the arcades of St. Mark's, the crowning ogees of the arches, distinguished as before, project respectively, 38, 26, 23, 31, 31 centimetres, from the same points from which the inclinations of the Byzantine arches were measured. To measure their actual forward inclination, we must, of course, deduct the depth of the moulding which surrounds them; but that this inclination, whatever may be thought of that of the Byzantine arches, was really intentional, will appear from the annexed dimensions of one of the two lowest vous-

soirs, which form the springing of the ogee of arch 5. (See Fig. 4.) *a* represents the front, of which the dimensions do not con-

cern us, *b* the side. *C* and *D* are right angles, and *AB* is laid horizontal. *AD* = 0.74. *BC* = 0.79. The inclination of *AD* is obvious.

In now quitting St. Mark's to add a few thoughts suggested by what has gone before, I will only note that, constructively, the upper arches are in a most perfect state of preservation, and we may congratulate ourselves that, now, at least for some time to come, they are to be left alone to nod to us undisturbed.

It is an axiom in all branches of the arts—and one, perhaps, specially applicable to architecture—that there often exist certain subtle qualities which, while they appeal to the appreciative senses by adding tone and elegance to a design, yet remain long, perhaps always, concealed. If, perchance, the mystery is discovered, and the problem solved, the satisfaction obtained adds to the pleasure derived, and the impression is complete. But our sympathies, on all subjects appealing to the taste, are so widely different, that I know well the impossibility of obtaining every reader's admission, that the feature which forms the subject of this paper is, or even may be, one of these refinements, the existence of which, however, all who claim to understand art, even in the smallest degree, must, certainly, allow. Inasmuch as there are those who would declare the noble swelling of the Tower in Air, at Florence, or the cunning curvature of Rouen's Tour de Buerre to be barbarisms, so I have already met with those, in whom the only sensation aroused by an inclining gable or pediment is, that it is going to fall on them. It needs but a passing glance at many of our modern buildings—if, indeed, they do express the feelings of their designers—to be led to the conclusion that any violation of the rule—not to mention the plumb line—means offence to minds whose ideas of architectural beauty seem to exhibit themselves mainly in either setting up so many columns or windows, side by side at equal distances, or endeavouring to persuade the public into their way of thinking, by writing apparently authoritative and learned criticisms on buildings which they cannot understand. From such, shallow ridicule only can be expected of a point which must be for ever in direct opposition to their principles. But from those whose sensations are not blunted by the perpetual consideration of equal feet and equal inches—symmetry "in all its branches"—may we hope for a development of a subject such as this, so that it may be placed, by careful reference to old examples, upon a sure footing. In its consideration, however, one point must be kept in view. If the bending forward is obvious, or is such as ever to reveal itself, the mind, being once aware of its existence, must be satisfied that there is ample support suggested to prevent collapse. Thus, if we felt that there was the remotest chance of those gracefully bending ogees in the Chapel of our Lady, at Ely, falling forward on us, they could never excite that delight in us which they now do. At St. Mark's an adequate sense of support is suggested by the shafts which, projecting from the wall face, but, at the same time, bound to it, and to one another by their bold and continued abacus, sustain the arches. At the Porta della Carta we are satisfied by the upright wall behind the gable into which we know it is well bonded. Again, in the Northern timber-framed constructions the very display of the timber alone suffices. Deceive us into feeling, in any way, that such building is of brick or stone, and we shun it immediately as dangerous. As a fitting instance of this head, let us imagine what would have been the effect if this inclination had been introduced—even in the least noticeable degree—into such a gable as one we used to know of (happily now we do not) in Oxford-street, W. We should have

had always to have passed by on the other side, which would have been unfortunate, as subjecting us to the greater chance of the disagreeable sensation of catching a glimpse of it.

I will conclude by expressing my best thanks for the generous and ready aid I have received from a Venetian gentleman in the consideration and working out of this subject. Indeed, without his help (he has supplied me most kindly with all the measurements I have been enabled to give, and, with many suggestions) this paper could never have seen the light. Of whom I would say, I only wish that there were many more in Venice eager to devote themselves with such unflagging zeal as he does, to every endeavour to instruct his fellow-citizens in a real appreciation of their glorious inheritance. VEDECE.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE second ordinary meeting for the present session was held on Monday evening, Prof. T. Hayter Lewis, V.P., in the chair. Mr. Fowler was welcomed by the chairman on the occasion of taking the office of hon. solicitor to the Institute, in succession to the late Mr. Ouvry.

EARTHENWARE POTS (CALLED ACOUSTIC VASES) BUILT INTO CHURCHES.

Mr. GORDON M. HILLS read a paper upon this subject, illustrated by twenty-two full-sized drawings of typical examples of these vessels. The subject had, Mr. Hills remarked, not previously been dealt with, except in scattered notices of the discoveries of pots in churches. The theory that they were intended for acoustic purposes had only arisen in the present century amongst French and English writers, but was based upon a statement by Vitruvius, which we now knew to be confirmed by a note by a mediæval monk at Metz. Vitruvius, writing at the period of Augustus, says (V. 5) that brazen pots were used in the construction of Greek theatres, under the seats, for the improvement of the sounds, and refers to minute mathematical rules which governed their position, but does not appear to have seen an example, nor to know the exact manner of their employment, and distinctly says they were not used in Rome, but that while there were a few instances in Italy, there were many in Greece. The next reference to the use of acoustic vessels is in 1432, but it only became known to the present generation about twenty years since. During the demolition of the Cîteaux monastery at Seans, a suburb of Metz, the records were examined, and an entry was found that in 1432 the prior had pots of earthenware placed in the church, as he had seen them used in some other church, to improve the chanting. He had all the pots fixed in the wall of one bay of the choir, and the chronicler added, "I do not know that they improved the chanting, but they disfigured the walls, and after a time people wondered why they were there. They are," he continued, "a marvel to all and a jest to fools." In 1665 the Abbé Saint Léger refers to the use of jars in vaults and walls of churches placed there to increase the sound. Our chief knowledge of these vessels was from the examples found in churches when undergoing alteration; but many very ancient instances of built-in pots had been discovered, as at Hierapytna, Saguntum, and Scythopolis. In Sweden a considerable number of these vases had been found. In the interesting church at Bjersjö, contemporary with, and not unlike, our Norman church of Kildwick, Herefordshire, as many as 40 vases were discovered to have been built into the walls, and others in the eastern apse, while yet more were believed to exist behind the chancel arch. Each was placed with the mouth upwards, and covered by an oak board perforated with a trefoil; in front of the series the wall had been built up at a subsequent date. Several examples had been found in French churches since 1842, as at Arles, St. Blaize at Montevilliers, and Fry. These French instances, as described by the Abbé Couhé, M. Viollet-le-Duc, the Rev. Mackenzie E. C. Walcott, and Mr. Albert Way, were generally found inclosed

near or in the angles next the nave; they were laid on their sides, with, in most cases, the mouths facing the interior of church. When the Late 14th-century chancel of the collegiate church of Youghal, Ireland, was being re-roofed in 1851-5, holes for jars were found in the north and south walls at intervals, and four still contained earthenware vessels. The English examples, especially in East Anglia, were numerous, the largest class being that where a series of jars were found to have been built on their sides into sleeper walls beneath the floors of the chancels. To this class belonged the earliest discovery, that made in 1810, in St. Peter's Church, Ipswich, those at Fountains Abbey, and at the churches of St. Peter Mancroft (40 jars), St. Peter per Mountgate (16), and All Saints (16), all in Norwich city, and all, like several other of the investigations, carried out and made by Mr. R. Makilwaine Phipson, of Norwich and Ipswich. Another arrangement of these jars was to build them into the inner part of walls. Of these, specimens had been found at St. Olave's, Chichester (two very small ones, supposed to be Roman jars, as other Roman work was re-used in the church), Upton, near Southwell (3), East Harling (4), St. Clement's, Sandwich (3), St. Clement's, Ipswich (3), and St. Mary-le-Tower, in the same town. One of the most interesting yields was that made in 1873 during the restoration of Leeds church, near Maidstone. Here as many as fifty large earthenware jars were found built into the 14th-century arcade walls behind the framing of a somewhat later roof. They all had convex bottoms, through which holes had been pierced when the clay was wet in regular patterns. The jars faced the interior of church, and were disposed at regular intervals which did not agree with the framing of roof. Some were placed in the Maidstone Museum, one was taken by a churchwarden, and others were dispersed or broken. Mr. Hills exhibited one as a practical illustration of his paper. Respecting the purposes of these jars opinions had widely differed. The general opinion of French archaeologists was that they were intended to increase the reverberations of the voice; but M. Didron, whilst concurring in this supposition, had remarked that the means adopted were "puerile." In England opinions were divided, the theories being that they might be used for ventilation, heating, and acoustics. If for the first-named purpose, he could not understand why they were bedded so deeply in the walls. As for those in the sleeper walls of floors beneath choir stalls, it appeared possible that they might have been filled with burning charcoal, but if so surely in some case there would be traces left or traditions existing of flaps in the floors above for access to them, but of these none were known. The supposition that they were used for keeping relics in was not tenable, he thought. It was possible the mural jars were intended for increasing the sound, but being found useless were walled up and forgotten.

Mr. E. P. LOFTUS BROCK thought these jars were introduced for acoustic purposes, perhaps as the result of the statements of Vitruvius: their utility must have been extremely dubious. To archaeologists the illustrations and specimens were familiar, as they represented the ordinary mediæval pottery in domestic use, discovered in many excavations in mediæval sites. The frequency of their discovery in Norfolk and Suffolk appeared to indicate that some one advanced a theory of their utility, and that the experiment was tried in several churches of the principal towns. Most church architects knew the difficulty of checking an echo rebounding from the west walls of churches; and it might be possible to break this resonance by filling it with pots of this character.

Mr. T. BLASHILL had examined the jars discovered at Denford, and thought their use was acoustical. Some thirty years ago he was told at the Broadway Inn, seven miles from Hereford, that the floor of the chief room used for dancing was laid upon horses' skulls, for the purpose of increasing the sound of the fiddle during dances. A few years since the inn was rebuilt, when it was found that under the floor of this room were three rows of horses' skulls, eight in each row, nailed through the eye-sockets to the beams of the floor. He had heard of a similar instance in Lancashire, and believed it to be a survival of the same custom.

Mr. A. CATES mentioned that in an early edition of Terence was a note by an unknown

commentator of an unknown period, referring to the use of vessels of brass for the purpose of increasing the melody in certain temples. He proposed a vote of thanks to Mr. Hills.

Mr. CHAS. FOWLER, in seconding the motion, referred to the ruined open-air theatre of Taormina, Sicily (Taormenium), where earthenware pots existed under the seats.

Mr. H. H. STANNUS suggested that whereas some of these might be for acoustic properties, those disposed along the nave of Leeds Church, Kent, with pierced bottoms, must have been rude attempts at ventilation—a difficult matter to secure through a wall of loose rubble.

The CHAIRMAN, in putting the vote of thanks to the meeting, remarked there seemed to be three distinct classes of these vases—those used for constructional purposes in vaults, those in walls, and those under the stalls of choirs.

Mr. G. M. HILLS, in reply, said he had intentionally abstained from alluding to vases constructionally used in vaults, which were by no means uncommon. As to the acoustic use of these vases, they appeared to have been firmly fixed, so that they could not vibrate with the sound. Those at Leeds, Kent, could not have been intended for ventilation, for they were buried in a solid wall, with 18in. of masonry between them and the outer wall, and the perforations in the bottoms had all been filled with plaster. It appeared possible that these vessels had some subtle effect on the acoustics of a building, and he could not understand any other purposes for their use.

LECTURES ON HORTICULTURAL BUILDINGS AT THE CRYSTAL PALACE.—II.

(Continued from page 654.)

THE second of the course of lectures to the students of the Crystal Palace School of Gardening and the public, was delivered by Mr. F. A. FAWKES, on Wednesday, the 23rd inst. at 5 p. m. After a recapitulation of the ground covered by the last lecture, Mr. Fawkes said the next point to raise would be in reference to the glass, and how it should be put in. For ordinary horticultural purposes, you will be safe in using English sheet glass, 21oz. to the square foot. A thinner glass, 15oz. or 16oz. per square foot, is often used, but is more liable to damage by hail, and to scorch the plants. Belgian sheet-glass is cheaper than English, but being more speckled, is not recommended. When permanent shading or screening by a semi-obscure glass is necessary, you cannot do better than employ Hartley's rolled plate, varying from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. thick, in which the obstruction is due to corrugations on one side of the glass. Experiments have been made with tinted glass, with the view of arresting the excessive heat-rays, while permitting the light and chemical rays to pass through, but they have not reached a practical stage. The choice of a glass is easy, but not so simple is that of a means of fixing it, for a great many different modes have been tried in which putty is abolished. Putty-glazing is by no means perfect: the putty is apt to peel off, crack, form crevices for the retention of moisture, and cause the woodwork to rot. Then it is troublesome to renew glass when necessary, as well to put it in in the first instance. No doubt putty-glazing is crude and unmechanical, and horticulturists would welcome any advantageous method of superseding putty-glazing, but for purely horticultural purposes no system hitherto invented has proved a successful rival of putty-glazing, and I cannot conscientiously recommend any of them for glazing purposes. In some cases the glass is held in its place by metallic slips, in others by compressible metallic bars, in others between slips of vulcanite or other elastic substance, the glass and vulcanite being held together by wood or metallic capping and screws; in others the glass drops into grooves prepared to receive it. In all these cases, the glass comes into contact with either a metallic or elastic substance. In the former case there must be a sufficient amount of "play," or the glass will break; in the latter case, atmospheric influences will rapidly decompose the elastic substance, when there is far more trouble and expense to replace such substance than to re-putty a house. If there be "play" between the glass and its supports hot air has opportunity for escape; the house cannot be properly

fumigated; crevices for the retention of water by capillary attraction abound, and the glass is liable to subsequent breaking by the freezing of this water. For other than strictly growing horticultural buildings mechanical glazing may frequently be employed with benefit, but for these structures a puttied roof is safest. If putty cracks it is because it gets too hard, and that may be avoided by putting a little tallow in when made—say nine parts good boiled linseed oil, and one part tallow mixed with whiting to required consistency. It is frequently recommended to employ bottom putty only, i.e., imbed the glass in putty, sprigging it at the top with copper tacks. This will prevent trouble from putty peeling at the top, but is not so slightly as the old plan. If top putty be used, it should not cover a large area of glass, and the surface of putty next glass should slope well, so as not to retain moisture. The glass should be cut with a lap of not more than $\frac{1}{4}$ in., or the water will be retained and may freeze and break the glass, and more dirt will be held between the surfaces than if the lap be greater than this. The sash-bars may be from 10 in. to 12 in. apart in an ordinary roof, and the panes from 2 ft. to 2 ft. 6 in. long. These panes should be rectangular; if the lower edge is cut in circular form, as sometimes recommended, the irregular capillary attraction will cause breakage of glass.

There are two other descriptions of roof not yet mentioned, the curvilinear and the ridge-and-furrow; but neither can be recommended by the lecturer. In a curvilinear roof the construction is more costly and troublesome; lateral thrust is not so easily overcome, training-wires are not so easily fixed, and ventilators not so easily adapted as in a straight roof. More important still, bent glass is more liable to break with variations of temperature than straight glass, and if straight glass be introduced the panes must be short and in different places, or they will not follow the curve of roof. An unsightly appearance is the result, and heat is lost and rain drifts in more than when the glass is in one plane. By a "ridge-and-furrow" roof is meant one composed of a number of small spans each not more than about 5 ft. wide. The chief objections are: it has a number of valley-gutters, and these are always difficult to keep watertight; such a number of valleys and ridges, in proportion to the area and the construction necessary to support these, form unnecessary obstructions to the light; and it is never necessary to have a ridge-and-furrow roof to cover ordinary growing-houses.

In discussing the details of these houses, the question of stages or stands for plants, &c., must not be omitted. The objects of a stage are: that it shall bring the plants nearer the glass; shall place them in such a position that they shall be more easily attended to; shall raise them away from any obstruction, such as hot-air pipes, &c.; and shall afford a means of easily draining them from superfluous moisture. The ordinary lattice wood stage is very suitable. It may be made of deal laths, say 3 in. by 1 in., having a space of $\frac{1}{2}$ in. between them, carried on bearers at short intervals, these bearers being supported by legs or brickwork. Sometimes a solid stage is advisable, when stone, slabs of concrete, or, more usually, slate is employed. These, having a raised margin and provided with drainage holes, can be used as shallow boxes (as for placing pots or plants in a damp bed of sand or moss), when wood boxes would be liable to rot, but are much more expensive than wood. A cheap form of solid stage may be constructed by taking an ordinary lattice wood stage, fixing a fillet on edge, so as to make a raised margin, and then line the interior with zinc (say, No. 20 B.W.G.), taking care to provide drainage holes for the shallow watertight box thus made. Iron stages are seldom used in growing-houses, but in show-houses are mere panels of perforated castings supported horizontally by a framework and legs of iron, or by other support. In planning stages for growing-houses be careful to study economy of space and convenience. Never have two paths where one will suffice, but at the same time do not let the stages be inaccessible. Let the distance of your stages from the glass be taken in conjunction with the length and size of the plants which will be placed upon them. Well-planned stages will cover the maximum space, will be accessible in every part, will present a neat, uniform appearance, and will exactly suit the plants they are intended to sup-

port. The proper height for the top of stage is about 30 in.; if lower, a good deal of stooping is required to attend them; if higher, they are less accessible and look awkward. Fig. 17

FIG. 17.

shows a suitable plan of stage for narrow plant-houses up to 12 ft. or 13 ft. wide. We have a path 2 ft. 9 in. wide, and this, with $\frac{1}{4}$ in. on each side occupied by woodwork, allows, in a 13 ft. house, 4 ft. 9 in. width of stage on each side of path. Market-gardeners prefer such houses about 11 ft. wide, permitting stages on either side each 3 ft. 9 in. wide, so that the plants and ventilators are readily accessible. For houses over 13 ft. wide, a span-house should have the staging disposed as in Fig. 18. Where one plant-house

FIG. 18.

succeeds another, it is better not to allow the two paths to converge into one at the division, but make them continuous, so as to obviate waste of space. (See dotted line shown across centre of Fig. 18.) There ought to be plenty of head-room in the paths and for the doors, and this will also regulate the width of your side stages. The centre stage may be either flat or tiered, depending on the width of this stage, the plants to be grown on it, and the light from glass. In lean-to or three quarter span-houses of a moderate width and not too short, the mode of arranging the staging shown in Fig. 19 is very

FIG. 19.

suitable. If the house is too short, the return ends may be omitted. Although the width of steps depends to some extent on the plants grown, it may be remarked that a great number of very narrow steps is not so economical in space as a smaller number of wider ones.

Ventilation is the next consideration in a glasshouse. As a consequence of the increase in volume with the raising of the temperature and *vice versa*, the displacement of the air produces horizontal as well as vertical currents, and so by a proper arrangement of openings and heating apparatus we may procure a renewal of air in our greenhouses. It is necessary that the fresh air brought in shall be warmed before it comes in contact with the plants, if possible. We must therefore place the inlet for renewal low, and also the means for heating it low, and must arrange that the current shall find its exit as high as possible. A heavy wind may neutralise the effect of this arrangement by causing the air to come in at the top and go out at the bottom, but this may be prevented by varying the size of inlets and outlets. As a rule, outlets may be of smaller combined area than the inlets. Both should be along the whole length of a house, except in the case of the top ventilators of a span or three-quarter span-house, which may be arranged alternately on each side of ridge. The usual form of ventilator is a framed light, hinged at the top and opening

from the bottom outwards. Sliding sashes have almost gone out of fashion except for frames, low pits, and roofs which have at times to be practically stripped. A roof containing sliding lights is abnormally heavy and affords great obstruction to the solar rays, and the sliding lights themselves develop great friction. The same objections apply to ordinary window-sashes used as upright lights. Ventilators pivoted in the centre are sometimes used, but are not so simple nor efficient. Casement ventilators may do for show-houses, but nothing can beat the ordinary lights hinged from the top. The size of ventilators will depend on requirements of plants; but for ordinary purposes the lower inlet ventilators may be about 2 ft. 6 in. deep, top ventilators about 2 ft., the width in either case corresponding to the distance apart of rafters, in a sashbar roof about 5 ft., in a sash roof about 4 ft. "Hit-and-miss" ventilators may be used in brick walls immediately in front of hot-water pipes, either in conjunction with vertical lights or where none exist. All ventilators should fit closely and butt against fillets. We have seen that it is necessary to have an uninterrupted area of top and bottom ventilation. Unless there is a great number of lights to be moved, it is advantageous that each ventilator shall open and shut separately, rather than all should move simultaneously. If the separate plan be adopted, then the ordinary "set-open," consisting of a bar having notches or holes in it setting on to a fixed pin, may be used. For separate top lights a quadrant bar terminating in an eye may be fixed to each light; a cord attached to the eye, and passing over a pulley fixed to the purlin or principal, will be sufficient to open the light. A counterbalance weight or hook in the wall may be used to keep the light open. A "set-open" for single roof-lights is shown in Fig. 20. When, to save time, or because they

FIG. 20.

FIG. 21.

are inaccessible, a range of ventilators has to be opened simultaneously, a round bar may be fixed to plunger blocks immediately in front of the ventilators, and two jointed arms fixed on each ventilator, and keyed securely on to the bar. In Fig. 21, a side view of one jointed arm and a section of the bar, and a light is shown. Upon partially rotating the gear, the jointed arm is straightened, and the light is forced open. A handle keyed on to the bar, and moving in a quadrant, can easily actuate the bar. The same apparatus may be used to actuate top lights. Care should be taken that the arms are all securely keyed on the shaft or bar; otherwise there may be a tendency to wring, and some lights may be closed while others remain open. Sometimes toothed quadrants are used for the simultaneous opening of lights, but these double jointed arms are far better. In vineries, cucumber houses, &c., provision must be made for training the plants over the glass, and trees are also often trained upon walls. For roofs the usual practice is to stretch the wires in a vertical direction, parallel with the rafters and sash-bars, so that the wires strengthen the roof and facilitate painting and repairs. In fixing such wires, say, in a lean-to roof, take two flat iron bars turned edgewise, and suspend them at back and front by holdfasts at intervals, bolted through the back wall and into the front mullions. Then stretch wires by radisseurs to these two bars. The wires can thus be at short or irregular intervals along the bars, and at any time the distances apart may be altered. The wire used may be No. 12 B.W.G., and may be from 10 in. to 12 in. below roof. If the roof be a span instead of lean-to, the flat bars will require to be held fast to the mullions on each side, and the wires strained between them after being passed through eyebolts, screwed to the ridge-plate, or

taken over an iron bar. Wires against a vertical wall are better placed horizontally, and may be 10in. or 12in. apart, each fastened to a staple at one end, and to a radisseur at the other, passing through guiding-eyes at intervals of 10ft. From 100ft. to 150ft. of wire may be strained in this manner with ease.

Painting is by no means an unimportant part of greenhouse construction. The woodwork should be well seasoned and thoroughly dry before any paint is applied. Any woodwork prepared at a distance from its destination should be well primed before it leaves the shop. Before it is fixed, those parts which come in contact with brickwork, and which cannot afterwards be accessible, such as the under part of sills, the back of wall-plates, &c., should be well painted with good oil-colour. After the woodwork is fixed, it should again be well painted. In all, no fewer than four coats of good oil-colour should be employed. The best finishing colours for horticultural work are stone colour and white. Bright prominent colours should never be employed in either growing- or show-houses. Such colours are certain to artistically kill all the plants and flowers, and it is, after all, the rich colouring of foliage and flowers, not the colours of woodwork, which we wish to make prominent. Horticultural buildings have very trying atmospheric influences to contend against, therefore protection by periodical painting is an absolute necessity. Supposing houses are properly painted when they are erected, they should have one coat outside within at least a year; after this, two coats outside every three years. When new panes of glass are put in, the woodwork left bare by the operation should be painted. In none of the diagrams to which I have already drawn your attention, is a provision shown for enabling vine roots to have simultaneously an outside as well as an inside border. As a vinery or a house with such borders possesses several distinctive features, I will give you a few notes regarding the construction of a vinery. Although some authorities advocate an inside vine border only, yet it is generally advantageous to allow the border to be outside as well as in, and to do this you require either to build the front wall of your vinery on arches, the crown of the arch being just under the soil, or to support the front part of your vinery on short iron pillars at intervals, the space between the pillars from the wood and glasswork down to a little under the level of the soil being filled by slabs of slate, as shown in Fig. 22, which is a section of front

required. About 2ft. 6in. to 3ft. is a very fair depth for a border, and the total width may equal the width of the house. The layer of rubble may be from 6in. to 12in., in accordance with the ease or difficulty in draining. In some instances it is advocated to run hot-water pipes through or under vine borders; but this you will scarcely ever find necessary. In planning your vinery it is advisable, if you can, to have part, at least, of your border above the ground level. Next to the vinery, the house most frequently required is the forcing-house proper, and, in this house the beds are raised to the necessary temperature by hot-water pipes placed underneath them. The path in horticultural buildings may be composed of stone, slate, bricks, tiles, concrete, or wood. The most favourite solid path is a tile one. Builders' ordinary 6in. or 9in. red and buff Staffordshire tiles, carefully laid diagonally, in cement, upon a good bed of concrete, form, at reasonable cost, a neat, durable, easily cleaned, agreeable-looking path. If such a path does not come against a dwarf wall, an edging, such as a stone curb or edging tiles, of which there are several standard patterns, may be used. Failing this path, or in positions such as on any inside vine border, where a permanent path cannot be laid, a very suitable strong lattice-wood path may be easily constructed of battens, say 4in. by 1½in., laid transversely on quartering, with ½in. spaces between, and a neat nosing on each edge; 2ft. 9in. is a very good width to allow for a path in a growing-house; 3ft. is, perhaps, better if you can afford to have it. If you are very much cramped for room, 2ft. 6in. only may be occupied by the path. You must be guided, however, by whether you have staging or any similar obstruction on each side, or an open path such as in a vinery.

(To be continued.)

FULHAM UNION INFIRMARY COMPETITION.

THE Fulham Board of Guardians met last Tuesday, and after some discussion of the report of the professional adviser, have awarded the first premium of 100 guineas to the authors of "Experience" in circle (Messrs. Giles and Gough), and the second premium of 50 guineas to the authors of "Simplicity" (Messrs. Young and Hall), in accordance with the recommendations of Mr. Currey. The discussion of the merits of these designs turned mainly, we understand, on the questions of cost and accommodation, and at the last meeting

departments by colour on the plan. With regard to plan, the competitors appear to have generally adopted the pavilion principle of distribution, and several of the authors have adopted four pavilions, two for each sex, and the administration block between, the pavilion being connected only by a corridor. The general arrangement shows the administration block facing Margravine-road with blocks on each side, and receiving wards; a few face the Fulham-road. The pavilions have in some cases been made to contain three wards each, and we hope the committee will insist on a good aspect to insure the direct action of the sun's rays. With regard to accommodation, the infirmary had to be designed for 360 patients, exclusive of separation wards for lock and infectious cases, the females being slightly in excess. The entire space allowed to each patient was for day and night wards 850 cubic feet, or not less than 72ft. of superficial floor-space, and 6ft. of wall to each bed. Each ward was limited to 32 beds, and to have windows on each side. We believe the guardians have strictly followed these conditions, and will select a plan capable of future extension, and of being rendered fireproof, and we trust that mere ornament will be discarded. As the designs, in all numbering about 30 sets, have not been made public, we can only now furnish our readers with the general characteristics of the two premiated plans. The site, which is a parallelogramic shaped piece of ground, at one end abutting towards the Fulham-road and fronting Margravine-road, adjoins the union workhouse, and measures 665ft. long in frontage, with a depth of 179ft. This proportion almost necessarily bound the competitors to a certain distribution of the plan, and we find most of them have adopted an arrangement in which the blocks are placed at right angles to the front.

The authors of "Experience" in circle, Messrs. Giles and Gough, have, we understand, a centre administration block with pavilions, two on either side, the separation wards for infectious cases being placed at the extreme ends, allowing room for future additions. The wards are 96ft. long by 24ft. in width, and have windows on each side. There is a wide space between the pavilions. A day-room is attached to each ward on the ground-floor, and on the upper ward floors is attached an isolation ward for special cases, besides a ward-kitchen, w.c.'s, and baths. The authors' estimate is £39,750, which includes ventilating apparatus, gas, and fittings. The external treatment is plain, and the elevations are designed to harmonise with the workhouse building, which is red brick, relieved by stone quoins and window dressings of a massive character.

The second design, "Simplicity," by Messrs. Young and Hall, of Southampton-street, is planned on the same principle. In the centre, the author places the administration block, with the residence of the officers in front, and on the right and left runs a corridor 8ft. wide, which gives access to pavilions of wards. The main entrance in this design is at the angle of the Fulham and Margravine-roads. The corridor connects the ends of the pavilions on the north side. The wards are 24ft. wide, the beds are placed in pairs between the windows, a space of 6ft. of wall is allowed to each patient—exclusive of doors, or a superficial area of 72ft., and a cubic space of 936ft. There are 28 male patients provided for in each ward, and 30 for the female wards. At the ends of each ward adjoining the corridor end is a spacious staircase and lift in the well-hole on the right-hand side of entrance, and a ward scullery on the other side, while on the opposite side of corridor is a projection for a day-room on the ground-floor, and an isolation ward to each of the upper floors. The corridor is closed, though the authors recommend in their report an open one. At the outer and extreme end of each ward are single w.c.'s, well isolated bath-rooms, and lavatories are also shown in good positions. The author places his receiving-wards at the connection of corridor near entrance, one to each sex, and the infectious cases are provided for at the extreme ends of the blocks. In the centre of the south block is the dispensary, and the arrangement of the administrative blocks, the kitchen, laundry, and offices are pretty complete. The external design is substantial, plain white stocks, with red brick arches, &c., being the main relief to the principal decorations. The authors' estimate is £40,923.

FIG. 22.

wall of vinery, having inside and outside border. A represents the slate slab, B iron pillar at each mullion, and C brick or concrete base. The drainage of your border must also be efficient. If the natural soil is too retentive, and there is no other way of accomplishing the purpose, you must prepare the bottom of your border in something else, as shown on Fig. 23, where A is outside border, A' inside border, BB drains, C rubble, D concrete bottom, E front wall on arches, and F the paths supported by piers at intervals. First put down a layer of concrete, then a layer of rubble with, perhaps, some small transverse drainpipes, then turf to prevent the compost filling up interstices of the rubble, then the soil of the border itself. In most cases a rubble bottom will be sufficient for drainage, and at the same time will form a barrier for the roots, in which case the concrete layer will not be

FIG. 23.

it was resolved, that the authors of these designs should meet and confer with the guardians upon them on the following Thursday. By the conditions of the competition, the Guardians did not bind themselves to carry out any or either of the designs, and it is probable they may find modifications necessary to meet their views. With regard to cost, the conditions state that the author placed first will not be entitled to carry out the work without a guarantee from a substantial contractor that he will carry out the same at a price not exceeding the architect's estimate by more than 10 per cent. The drawings are made to a small scale, 1-16 of an inch to the foot, and many competitors have sent a plan of one ward to an eighth-inch scale. No perspectives were to be sent, and the drawings, we understand, are in line only without colour. A few authors have distinguished the

BUILDING STONES OF SCOTLAND.

AT the meeting of the Edinburgh Architectural Association, on the 16th November, 1881, the president Mr. McLachlan occupied the chair, and in a few words introduced the lecturer, Mr. Gowans, who then proceeded to read his paper on the "Building stones of Scotland." No inquiry can be more interesting or of greater importance to the architect and builder than that respecting the nature of the material which they have to use in the buildings they may be entrusted to design and erect. From the Solway on the south to the Pentland Firth on the north this country is full of a variety of rocks suitable for building purposes, and this is shown by the massive, elegant, and enduring structures of past ages, edifices of so much value both historically and architecturally. When the appliances for quarrying were of the most primitive kind, and the means of conveyance to any distance a work of great difficulty, the architect was forced to adopt a style of building suited to the material nearest at hand; but now with railways interspersing the country he is not tied down to any particular stone or material, but may adopt that which he finds best suited for his purpose. What the architect has to look for is a stone that will be *durable, strong*, and of a colour which will best bring out the architectural features of his design. With the view of noticing stones that have been used in some of the oldest structures before referred to, as well as those of more modern date, I have had cubes of sandstones and granites prepared, so as to bring before the Association in a practical way some information respecting those stones most useful for building; and, to do so, I would begin by noticing the building stone that has been used in our own city. In the older buildings, such as Heriot's Hospital, Holyrood, and the residences of the Old Town erected centuries ago, the supply was drawn from quarries in the immediate vicinity, an example of which is shown in specimen No. 1, taken from the old red sandstone found on the southern side of the town, which has been tested by time, and proved to be of the most durable kind. In the New Town, when quarrying appliances were better understood, other quarries were brought into use, such as Craigleith, Ravelston, and Redhall. These were chiefly used before the canal and railways afforded the means of bringing stone from greater distances. Then Binnie and Humble by the canal, and later on by railway such quarries as Denmore, Polmaise, and Plean in Stirlingshire, Dalmeny in Linlithgowshire, Fairloans, near Hawick, and the quarries of Lanarkshire, such as Overwood, Giffnock, Auchinclee, and Dalzell, specimens of which are now before you. The respective qualities of the stones I have referred to I will now notice; and taking together Craigleith, and Redhall, as occupying the same position geologically, (being of the lower sandstones of the carboniferous strata, or perhaps better known as the carboniferous limestone groups) their analysis may be taken as an index of what goes to constitute stone of the most enduring kind, viz.:—

Silica	98.3
Carbonate of lime	1.1
Iron and alumina	0.6
	100.

To specify examples of these in the city, as affording proof of their durability, I would notice—1. Craigleith, as shown in the Old University, and many of our finest squares and streets in the northern portion of the New Town, while a notable example, not only of the stone but of what I consider the best masonry in the city, is the tenement at the northern corner of Randolph Clif. 2. Redhall, St. Paul's in York Place, and St. John's, in Princess-street, as public buildings, are good specimens of this stone as to durability and quality, the carving on them being as sharp now as the day it was chiselled. 3. Humble and Binnie quarries belong also to the carboniferous limestone group amongst the shales. The Humble stone was greatly used some thirty-five years ago, and specimens of it are to be found all over the city, but it was abandoned through being unable to compete with other quarries. 4. Binnie may be set down as a stone of the first class. The first prominent specimen of it was the New Club in Princess-street, built about forty-five years ago, and adjoining it the palatial building of the Lin. Association of Scotland. The following public buildings were also taken from it, viz.:—

Scott's Monument, National Gallery, the Bank of Scotland, British Linen Company's Bank, Commercial Bank, Donaldson's Hospital, and the Post Office. Owing to this quarry being situated among the shale beds, the best fakes are saturated with bitumen, and this is so abundant that I collected a quantity and sent it to the Exhibition of 1851 in the shape of black candles, which the jurists simply noticed in a very short paragraph. Stones that have been extensively used since the advent of railways are those of Dunmore, Polmaise, and Plean. These all belong to the upper part of the carboniferous limestone group, the two former, however, lying above the Plean sandstone. These stones have been greatly used, not only in this city, but in Glasgow, and from Stirling northwards. They are pure sandstones, having a large proportion of silica in their composition. Buildings from Dunmore are New Post Office, Bank of Scotland, Merchants House, and Union Bank extension, Glasgow. These stones are preferred for their pleasing colour and durability, while the cheapness of dressing them overcomes the expense of bringing them from such a distance. The Dalmeny stone is of more recent introduction, but perhaps one of the best tests of its durability is that of Dalmeny Chapel, which was no doubt built out of the same strata, so long ago that little or nothing is known of its history except what can be obtained from its architectural character. Another stone in the immediate neighbourhood, is that of the Hailes, which has been worked for 200 years at least. This stone, owing to its laminated structure, is used greatly for foundations of buildings, piers, steps, &c. A stone which was used in the renovation of St. Giles's Cathedral about fifty years ago, (now being so admirably restored to its original architectural beauty through the munificence of Dr. Chambers and the careful superintendence of Mr. Hay) was taken from a quarry lying to the west of Burntisland, called Callaloe. This quarry was for a long time abandoned, until it was reopened by the late Mr. Bryce for the erection of Fettes College. The stone is durable, but owing, I believe, to the expense of quarrying and difficulty of dressing, it has not continued in use. Another stone in the same district as the above is that of Grange, which has been long in use, particularly in Leith, and a specimen of which is to be seen in Dalkeith West Parish Church, built about forty years since. This stone belongs to the carboniferous series, below the shale, and about twenty fathoms above the Burdiehouse limestone. In mentioning Burdiehouse I am reminded of the Straiton stone, which lies almost in the same position geologically as the Grange, and Dalloch in Fife. Another stone which has been brought into Edinburgh, and which is of excellent quality, is that of Fairloans, near Hawick. It is capable of a high polish, and greatly used for monumental purposes. It will be observed from the following analysis it is formed nearly of the same chemical ingredients as Craigleith and Redhall; and this refers also to such quarries as lie in the Bannockburn district, such as Dunmore, Polmaise, and Plean:—

Sand	95.64
Oxide of iron	1.62
Carbonate of lime	1.20
Carbonate of magnesia	0.52
Moisture	0.60
Loss in analysis	0.42
	100.0

Going westwards into Lanarkshire, and treating of stone used largely in Glasgow, as well as brought to this city, the Kenmore Quarries may be first mentioned. They belong to the carboniferous limestone, and lie above the Bishopbriggs coal-beds. They were worked to a great extent for many years, but now, I believe, are abandoned. A section of this rock may be seen at the upper end of the Queen-street Tunnel, Glasgow. Of the best stones, among many others in this county, are Giffnock and Overwood, both near Glasgow; also Auchinclee and Dalzell, and the Wishaw Quarries, all of which are among the upper beds of the coal measures. Among the buildings erected from Giffnock Quarry, in Glasgow, are the Academy, Herald Office; from Overwood, new Municipal Buildings, Greenock; City of Glasgow Bank, and new Stock Exchange, Charing Cross Hotel, and Clydesdale Bank, Glasgow. Another stone of reddish colour, which lies immediately over the coal measures in the bottom of the new red sandstone, near to

Hamilton, is of good quality, and is used extensively in that and the surrounding districts. This stone is exposed in a quarry which may be seen from the Caledonian Railway Glasgow line. Before leaving this county, Bellside Quarry may be noticed. It lies in the true coal formation. Going south and west we pass through stone strata, both yellow and red in colour. Of the latter, the Ballochmyle stone, of which the magnificent viaduct on the South-Western Railway is built, is a fair specimen. Further on, we get into the old red sandstones of Dumfriesshire, of which specimens are submitted. To the east there are the yellow sandstones of Langholm Hill, as well as the red sandstones found in the Hoddam district, all of which are good building stones.

Coming back to the north of the Tay, the old red sandstone is found to overlie the country from Lochlomond along the face of the Gramscians to Montrose, where stones for building purposes are to be found. The most important workings of this strata are those of the quarries which supply Dundee. Mylnefield Quarry may be noted for a stone not only durable but capable of resisting an enormous pressure without fracture—so much so that in the erection of the Ballochmyle bridge, before referred to, that stone was carried across the country at great expense to form the ringhead of the centre arch, which has a span of 180ft., and a height from the bed of the river to the keystone of the same dimensions. In mentioning this quarry, one is surprised that in restoring the Tay Bridge such stone as this is not used, instead of a combination of artificial material such as brick and iron. The crushing strength of this stone is given at 425 tons per square foot.

In speaking of Forfarshire, I cannot fail to notice the quarries which supply pavement, not only to this country but to all parts of the world; and as one of the industries of that county, and as showing the development of that trade, the Carmyllie Quarries, near Arbroath, fifty years ago, were worked by the aid of a single-power crane and a windmill for pumping the water from the bottom of the working, the few stones got in that way being carted a distance of about seven miles across the moors to Arbroath for shipment. About twenty-five years ago, in connection with the late Earl of Dalhousie and a friend, I made a railway from the main line to the quarry, which has had the effect of developing the trade to such an extent that, instead of the windmill and the old crane, there are now ten planing machines, besides stone-cutting machines, moulding machines, &c., worked by seven steam engines, showing the extensive use that is made of that stone not only for paving, but for steps, piers, &c. Specimens are now laid before you. The crushing strength is given at 500 tons per square foot. In speaking of the old red sandstone as useful for paving, the Caithness stone must not be overlooked, and for wear and tear it takes precedence of all others. As another branch of industry the development of this trade is quite as important as that of the Forfarshire stone before referred to. As an example of the value of this stone when subjected to continued wear and tear, the pavement in front of the New Club may be quoted, which was laid down forty-five years ago. Another example showing the same quality of durability, and also the size of stone that can be produced, is that in front of the Register Office, which was laid when the screen wall of that building was set back some thirty years since. The crushing test of this stone is given at 420 tons per square foot. In referring to sandstones, the length of this paper precludes me from giving in detail a description of the numerous quarries and the immense quantities of good stone that lie along the eastern edge of the Moray Firth, of which Elgin Cathedral is a most notable specimen. Besides the care which the architect and builder should take to make themselves acquainted with the nature of the substance of which the stone they are to use is composed as to its durability, it is of importance, where great weight has to be carried, that its power of resistance to pressure should be known, as well as its tensile strength. The difficulty, however, is to ascertain from the compression of small cubes the relative strength of what the same material would be if enlarged in size. This was very forcibly brought under my notice by taking part with the late Mr. Buchanan, C.E., in testing stone and brick for the chimney of the Edinburgh Gas Company at the North Back of the Canongate,

erected in 1845. These tests were made in the most careful way, by crushing cubes of 1-inch square of stone from the following quarries:—

RESULTS OF TESTS.

Crushed at	
Craigleith	315 tons per sq. foot.
Humbie	240 "
Hailes	225 "
Redhall	215 "
Binnie	182 "

A second test of Craigleith showed that before being crushed to powder it sustained a pressure of 440 tons per square foot. The appearance after fracture of the different cubes was that of a pyramid or wedge, and this led me to assert that if the cubes were enlarged a greater increase of strength would be gained; and further that if the pressure was vertical to the line of cleavage a greater resistance would be got, so that such a stone as Hailes, which is a laminated stone, would increase in strength according to its surface, more in proportion than that of a liver rock stone, such as Craigleith, Redhall, or the other stones that were tested. This led to discussion and further trial, the result being that with a 4in. cube from Hailes quarry the resistance was equal to 567 tons per square foot. It may be worth while to give the results of the experiments we made in testing the brick. A great many different kinds of bricks of different composition were tried, the result being as follows:—

No.	Description of Specimen.	Dimensions.			Weight.	Crushing Weight on each brick.	Crushing Weight per sq. foot.
		Length.	Breadth.	Thickness.			
0	Common fire-brick.	9	4½	2½	7½	89½	311
1	Extra size and quality from Mr. Livingston, brick work, fireclay, and ironstone.	10	5	3	10½	153	440
2	Do. do.	9½	4½	2½	9 5-16	140	448
3	Do. do.	9½	4½	2½	9 5-16	89½	287
4	General Quality	9½	4½	2½	9	63½	204
5	Do. do.	9½	4½	2½	9	140	444
6	Same quality as specimens sent to Glasgow	9½	4½	2½	7 4-16	51	150
7	Common stock brick taken at random from a building	9½	4½	2½	8	51	150
8	Do. do.	9½	4½	2½	8	25	78
9	Common general quality bedded with milled board.	9½	4½	2½	2	51	168
10	Do. bedded with clay	9½	4½	2½	9	140	448
11	Do. do.	9½	4½	2½	9	153	489
12	Stone from Hailes Quarry	4	4	4	5 11-16	63	567

As to tensile strength, this is also important to the architect where corbelling, steps, piers, &c., have to be used, as well as in stones which have to be placed over voids, where both crushing and tensile strain are combined. The following were the results, after careful and repeated experiments:—

Breaking weight.	
Craigleith stone	453 tons.
Hailes stone	336 "
Redhall stone	326 "
Humbie stone	283 "
Binnie stone	279 "

Although I did not test Arbroath and Caithness pavement, the following may be taken as safe:—

Arbroath	567 tons per square foot.
Caithness	417 "

As to the resistance to pressure and tensile strain, the architect and builder should, after satisfying themselves as far as tests can, keep in view that the stability of the structure depends a great deal upon the proper constructive use of the material. Unless stones are fairly bedded, there will be weakness and fracture, and unless the style of masonry adopted admits of every stone taking its equal share of the superincumbent weight put upon it there will be failure. This leads me to notice what I have observed with regret in the architect or engineer mixing the character of the masonry in such a way that one stone has more to bear than another. I have seen viaducts, for instance, built with rubble masonry of all sizes in the piers, while the corner-stones were made of increased dimensions, the result being that when the strain came, these corner-stones were frac-

tured by the load pressing unequally upon them. But this leads me away from my text, so I hesitate to go further.

Another consideration for the architect is using stone which absorbs a great quantity of moisture. I have found, for instance, extensive buildings erected in a wet country with a stone which absorbed moisture to such an extent that the dampness which penetrated the walls not only rendered the house unequal in temperature, but led to the decay of the timber which passed into the walls; and caused what was called "dry rot," but what was really nothing else but wet rot, or timber taking consumption from lying in a damp bed. Vitruvius, the Roman architect, 2,000 years ago, says some very wise things both as to stone and timber. He recommends as to stone that it should be quarried in summer, and seasoned, by being allowed to lie two years before being used, so as to allow the natural sap to evaporate and test the stone as to its wasting; and for timber, he says, it should not be cut down in the spring but in the autumn, when nature is dormant. But this, again, I feel is leading away from my subject, so I come back to treat on Granite. Following up the northern district, I may take, first, what has been done by the well known firm of Messrs. Macdonald, Field & Co., from their extensive quarries all over Aberdeenshire. Fifty years ago the uses of this enduring material were confined chiefly to local purposes, although long before then a considerable export trade was done in street pavement, as well as more important works, such as lighthouses, docks (Portsmouth), bridges (Waterloo and London). The development of its various uses, both red and grey, was brought about principally by the energy and enterprise of this firm, while by the introduction of machinery that obdurate but enduring material can now be dressed with the greatest accuracy and finish at a cost greatly less than could be done when operated on by hand. Other gentlemen who have developed this trade were the late Mr. Gibb, and latterly and at present Mr. John Fyffe, whose quarries of Kemnay and Cove, near Aberdeen, are the largest in the country for the production of stone used for curb and paving, as well as for the larger blocks required for such works as the Thames Embankment, part of which he supplied. There is so much to interest and instruct in a visit to the works of Messrs. Macdonald and the quarries of Mr. Fyffe, that members of the Association could not spend a more useful holiday than in going to see the various applications of machinery in dressing and polishing such a stubborn stone, where columns and such like are turned with as much apparent ease as that of the wooden baluster of a staircase. Specimens of granites from the quarries of Messrs Macdonald, Field & Co.; Mr. Fyffe, and Messrs. Shearer, Field & Co., are on the table, as well as a stone showing a very singular junction of colour, one half being of a beautiful red, the other grey; and this, I understand, divides the hill in a straight line from top to bottom. Returning to the south, I have to mention the extensive quarries and dressing machinery of Messrs. Shearer, Field & Co., and Messrs. Newall & Co., at Dalbeattie. The Dalbeattie granite is obtained from deposits on both sides of the river Urr, near the town of Dalbeattie, in Kirkcudbrightshire. In colour it is a bright, clear grey. It is a hard, close-grained granite. The close aggregation of its different minerals is a very important feature in it, and makes it well adapted for engineering and building purposes. It is also very suitable for ornamental purposes, as it is uniform in the grain, takes a fine polish, and is agreeable in colour. This granite was brought to the front for engineering and paving purposes about twenty years ago by Mr. Hugh Shearer, of Great George Street, Westminster. He had the first contract for the supply of the granite for the Thames Embankment at Westminster, and got it approved and introduced into that great national work. Since then he and his firm have steadily and energetically used it in many other important works, such as docks, bridges, fortifications, lighthouses, and fronts of buildings. The same granite crosses the country much in the route of the Portpatrick Railway, and was used for the principal viaducts on that line on to Creetown, where at Kirkcudbright extensive quarries were opened by the Liverpool Dock Trust, who not only built their dock walls with it, but the dock offices and sheds. It is worth noticing that the engineer

who first opened up these quarries adopted a style of building by using the blocks at random, of all shapes and sizes, the same as was done by the Roman masons, and which, apparently, has the same endurance as to structural stability.

I come now to speak of the value of this material with regard to its strength. While tests have been made to ascertain its resistance to pressure, too much dependence must not be placed on results given in text-books. Granite, like other material of which I have had experience, has a cleavage the same as sandstones have, although this is not the popular opinion, and would be condemned by the orthodox geologist, as it touches on the theory as asserted of granite being an igneous and not an aqueous rock. I mention this not for the purpose of geological dispute, but to reiterate what I have before asserted as to sandstone—viz., that to use granite so as to get the greatest resistance to pressure, the stone should be used so that the force should be at right angles to the cleavage or bed of the materials. That brings me to this, that granite, like sandstone, laid upon its natural bed, will increase in strength in the ratio of its superface. However, I repeat as to crushing that if granite is fairly bedded on an equal and resisting foundation no load can in ordinary circumstances crush it. It may be safe enough in dealing with granite, to take from 684 to 848 tons per square foot as a fair test of its strength. The remarks I have made as to granite apply also to other rocks such as trap, Graywacke, and mica-schist rocks, which are to be found in districts where sandstone may be too expensive to use. The method of using these for building is admirably shown in Hawick, Galashiels, and places where such stone is readily found. If properly treated nothing can be more enduring or more suitable for harmonizing with the landscape of the district in which it may be placed. A popular fallacy is that these rocks draw damp. This is not the case, they condense the atmosphere in the same way glass does, and if this is provided for in the building, there is not the slightest danger of any water penetrating the walls. In acknowledging the honour you have conferred upon me in asking me to bring this paper before you, I feel that the short time I have had for preparation has not allowed me to give the subject the justice it deserves, neither would one lecture be sufficient to exhaust it. I feel very much in the position of a hewer who has merely roughed the stone, and who has not had time to continue the operations, necessary to give that finish to the surface which might develop beauties and results that could never be seen in the rough. The selection for use of a material such as building stone goes much further than ordinary observation. Enduring structures speak not only of the habits of the people, but of the civilisation they have attained. The enduring Pyramids of Egypt, the ancient buildings of Greece and Rome, the Temples of Cambodia (which country has no history except in the elaborate limestone buildings which remain), show that the profession of an architect has to do with what every nation should prize, that is, to all time their architecture should faithfully represent, as far as it can, the people with whom it originated.

The lecture was illustrated by specimens of the various stones referred to.

At the close Mr. Lorimer proposed, and Mr. Whitelaw seconded a vote of thanks which was heartily accorded. Mr. Gowans having replied, the meeting dispersed.

BEDFORD PARK SCHOOL OF ART.

THE new school of art at Bedford Park, Chiswick, of which we give a perspective illustration and description elsewhere, was opened on Saturday evening last. Mr. Jon. T. Carr, the founder of the colony, gave a dinner at the well-appointed club to the members of the committee and a few guests. An adjournment was then made to the new school of art, where a soirée took place in the large galleries, followed by some speaking. The paintings and drawings exhibited included Miss Clara Montalba's picture of the golden "Piazza of St. Mark's, Venice, inundated," and two fine paintings by Mr. G. F. Watts, R.A. Mr. Walter Crane and Mr. T. M. Rooke were represented, the latter lending "King Ahab's Coveting." Messrs. E. Blair Leighton and H. M. Paget sent contributions, and a river scene was shown by Mr.

F. W. Hayes. Several members of the school committee lent examples of their work, including, for example, a seascape and boating incident by Mr. J. Nash, and some of Mr. E. Hargitt's landscapes. Messrs. Bernard C. Collier and T. E. Harrison were among the contributors. Several engravings and paintings were lent by residents and friends, including Messrs. Moncreu Conway, A. Dawson, Maurice B. Adams, E. R. Hughes, and A. Smith. Mr. W. G. Connell lent some engravings by Albert Durer, and Messrs. Bedford Lemere & Co. exhibited a selection of views taken from their series of photographs illustrating the buildings of Bedford Park. At the soirée, a selection of music was prepared under the direction of Mr. C. J. Harcourt, including a four-part song by a male voice choir, in flageolet solo by Mr. Lazarus, and a song by Miss José Sherrington. At the subsequent meeting in the same galleries,

The Right Hon. A. J. Beresford Hope, M.P., who had been asked by Mr. Carr to preside, expressed the great pleasure he felt in being present, and his gratification at becoming personally acquainted with one more of the noble network of institutions which was spreading the knowledge of art throughout the country. He was gratified to find such a school established in the midst of the dwelling-houses at Bedford Park, which had combined artistic elegance with the conditions necessary for health and comfort. They were, he thought, taking part in the inauguration of a school of art, not of the ordinary kind, but one which would probably take a foremost part amongst its brethren. He was sure those who came to it to study, would not regard the time spent within its walls as a mere pastime. Those who entered art schools might be divided into three classes: those who went there for technical education—a noble band of self-helpers, to whom he did not purpose just then to speak; those who went there merely for drawing lessons, and to whom also he should prefer to say no more; and a third class, to whom he would now address himself—those who, whether they had taken up the study of art as a profession in the highest sense of the word, those who entered thoroughly into the work, and intended to derive from the instruction all the advantage they could gain. Education in art involved a great deal more than a mere mechanical facility in transferring to paper or putty the form which the student had placed before him. He could emphatically assure them that he was not inviting them to join in what would merely be a source of pleasant and refined amusement, and holiday pastime. This art education was a great instructor of the mind and soul, as well as of the hand in the laws of colour, in measure, in proportion, in the relation of thing to thing in all that formed the judging faculty in man, teaching him to perceive and analyse. Proportion was indeed at the bottom and root of all things, physical, moral, and spiritual, developing the reasoning and judging faculties, teaching men to reason, and preventing them from being led away by first impressions. A very eminent surgeon of the day, who began life in an artist's studio, told him how much benefit he had gained in the practice of his profession by the training of the hand in neatness, and of the perceptive faculties in discrimination which he received in the study of water-colour drawing. So in architecture. Delicate discrimination, which enabled the designer to satisfy the eye with some subtle moulding or curvature, was only to be learnt by the careful and assiduous study of drawing. He would implore the student to remember that success was only to be gained by hard plodding work. Precept upon precept, and in every sense of the word line upon line, must be their motto, for those beautiful works of the great artists which seemed to have been produced with so little pains were probably the quintessence of deepest study. A design in outline was what it was, because the artist had been enabled by continuous study to know with how few touches a desired effect could be produced. Some might say that in adopting, as he had done, such hard assiduous study, he had taken very high ground, and that the majority of the students were not going to be great painters. He supposed that in the room there were in all probability no Michael Angelos, no Rubens, no Turners; but was it not a miserable excuse for a student to offer that he had not done, and could not do, his best because others in the world could probably do better. He besought them not to

be discouraged by any adverse circumstances, even by failure at the first, but to enter for the examinations with good heart, good will, good temper, great determination to succeed, and a dogged principle of assiduous drudgery.

Mr. T. Armstrong, the recently-appointed director of the art department of South Kensington Museum, said, with his very short experience of seven weeks in public life, it would be presumptuous in him to talk of the vast machine governed from South Kensington, but he might indicate the tendency of that central institution. No absolute change would be made, but he believed there would be some fresh developments to suit new requirements. His wish was to encourage and stimulate modelling from the figure, and also drawing from the figure, and also to promote the formation of life classes. The painting of still life may have been a little overdone, in centres where it was possible to obtain living models. The tendency of the department would be, he believed, more and more not to make painters of pictures, but to foster the study of design in connection with the industrial arts and manufactures—an object which he trusted the technical schools now being formed would help to produce. It was an evidence of the great stride that decorative art teaching had of late years made in England that he had received recently at South Kensington two deputations from the French Government of gentlemen and experts who had come to report respectively on the financial and executive systems of our art schools. In Paris, it was now thought that we were getting ahead of them, especially in design for furniture; and, altogether he considered there were good grounds for hoping that we should, before long, take a good position in art matters. The new school in which they were met was very comfortable, (and that was a great matter) and very well appointed with an excellent selection of casts, and, he believed, excellent masters. The dwellers at Bedford Park were much indebted to Mr. Carr, who was the Moses who had brought them out of the desert and wilderness of filth which lay behind them to the east. They had he had seen a very good church, a comfortable club, an aesthetic "pub," excellent stores, and last, but not least, this beautiful school of art.

Mr. George Augustus Sala proposed a vote of thanks to Mr. Beresford Hope for his conduct in the chair and for his encouraging address to students, and coupled with it thanks to Mr. Armstrong for his remarks. As he heard the latter gentleman he was reminded of Haydon, the real master of Landseer, and of his struggles for many years to induce the Government to establish schools of art. Haydon wore out the stairs of Downing-street by his persistency; but at last, in two lines, the Duke of Wellington told him that "there was no chance of the Government giving a halfpenny for the purpose." In an amusing speech, Mr. Sala said this was his first visit to Bedford Park, of whose very existence he had been ignorant. Ladies and gentlemen appeared incredulous; but London was so vast and one's opportunities of research so limited, that who could say there was not a Ghetto, a seraglio, a very Pompeii, to be discovered within its limits? But more than 40 years ago he went to school at Turnham-green, at a Pestalozzian school kept in Bolton House, since reduced to a shell, and he recollected that an ornate design of his was worked out in plaster for an Italian gentleman in Leather-lane, Holborn, and was placed over the doorway of the school, where it remained for many years. It represented Minerva rewarding the young gentlemen of Bolton House School with cornucopie, compasses, and beehives.

The vote of thanks was suitably acknowledged by the Chairman.

TESTING TRAPS.

LAST Saturday a series of experiments to test the merits of the various closet-traps in the market was made at Messrs. J. Pullen and Son, of Penton-place, Kennington-park-road. Messrs. Pullen and Son desired to prove the correctness of the experiments which have been published respecting their trap, and appointed a committee of practical plumbers to finally test the subject. Owing to the number present, and the difficulty experienced by several of the visitors present of examining the action of the traps on a scaffolding erected for the purpose, the results of the

tests were very inconclusive, and many came away rather dissatisfied with what they saw and heard, or rather with what they did not see nor hear. An adjournment of the meeting was made to Monday last, when we had a better opportunity of examining in detail the experiments made.

It will be remembered that some plumbers lately expressed doubts of the accuracy of Mr. P. J. Davies's reports of his experiments, and these tests have been made for the purpose of placing them above suspicion. The tests we saw bear out in the main the results published in our issue of Oct. 21, page 540.

The scaffolding erected in Messrs. Pullen's yard surrounded a 4in. soil-pipe, or funnel as it is called by the trade, about 45ft. high, and into these were short branches for the traps. The distance from the plug in the upper basin to the water-line of trap was only 6½in., and not, as stated, 18in. The experimenters commenced with a trial of the old-fashioned O-trap, a form of trap better adapted for large volumes of water than the "Helmet" trap of Messrs. Pullen, which has a rounded bottom and holds less water. Measuring, we found that the seal or dip was 1½in. The basin, one of Underhay's, made by Bolding, was filled with water, and the momentum of the rush left ½in. seal. The second test was with Pullen's "Helmet trap." The water seal was 1½in. Having been filled with water, and the plug of the basin raised, the water seal was found to be ½in., and this seal could not be reduced. The next test was made upon an ordinary S-trap, one of Beard and Dent's cast-lead S-traps. The water seal was 2½in., and the trap was used without an air-pipe on the outlet. When the plug was raised the water in the basin rushed through the trap and unsealed it, leaving about ½in. space between the dip and water-line of trap. A close inspection further showed that the loss of water by the momentum of the rush from the basin is partly made up by a portion of it which falls back into the trap, but this is not enough to reseal the trap. A 2in. air-pipe was then fixed, and the first basinful released left a ½in. seal, and another trial unsealed it to the extent of 1½in. Another test with a 3in. aperture gave a similar result, the trap becoming unsealed, and the same experiment repeated with a pipe upon the aperture did not improve matters. The "Eclipse" trap was next tried for momentum. There was a dip of 1in., and the basin plug being raised, the first rush unsealed the trap to the extent of ¾in., although air was supplied through the soil-pipe.

After these tests to show the momentum of the water on the various traps, the ordinary O-trap was tested for siphonage. The water was thrown down from the top of the soil-pipe about 20ft. above the trap. With ventilating aperture stopped up, the trap was unsiphoned with the first charge. A second trial with the valve shut, left the trap unsiphoned, but there was more drag, and the seal was reduced to a less amount. With the ventilating aperture on the top of trap open and the valve closed, the charge of water unsealed the trap to the extent of ½in.

The "Helmet" trap, with a seal of 1½in., after two or three tests, retained a water seal of ½in. under all conditions. The "Eclipse," on the other hand, became unsiphoned to the extent of ½in., with the ventilating aperture closed, while with it open, the trap maintained its seal of about ½in.

The experiments, which were conducted with the object of trying severely the seals of the various traps under sudden flushes, showed that the O-trap, whatever the faults of the old form may be, has at least the advantage of preserving its seal under the usual conditions; that as regards momentum of water, its water seal cannot be destroyed, and that it is not so easily siphoned out as other forms of unventilated traps. With regard to clearing action, we prefer the "Helmet" O-trap of Messrs. Pullen; the rounded water-way or bottom is better acted upon by the flush; it retains less water, and the form and construction of the trap give it many of the advantages claimed for the siphon. When large quantities of water are used, therefore, in valve closets and sinks, the O-trap has certain advantages over the S-trap, and it is in reference mainly to these points that the experiments are chiefly conclusive.

THE CABINET TRADE.

ON Wednesday night a largely attended meeting of journeymen engaged in the cabinet trade, including cabinet-makers, chair-makers, carvers, cabinet turners, and shop-fitters, was held at the Loyal United Friends' Hall, Banner-street, St. Luke's, "to take into consideration the present position of cabinet-makers, and the best means of improving the social condition of the operatives engaged in the cabinet trade." The chair was taken by Mr. Negus. Mr. J. Pither moved, "That, seeing the great want of organisation in a large number of shops in the cabinet trade, and the severe competition between many of our employers, this meeting is of opinion that were the men in our trade unionists, our social position would be improved, and the remuneration received for our labours greatly increased." Mr. Cammage seconded the resolution. Mr. H. Ham, in supporting the resolution, said that in 1850 the exports in the cabinet trade amounted to £182,619; in 1860, to £221,619; in 1870, to £231,000; and in 1880, to £480,521. In the face of that how could it be said that trades unionism acted in restraint of trade? In conclusion, he admitted that they were now better off, as they got 9d. an hour instead of 6d. as formerly. Mr. Jolliffe said that in some shops men were paid so badly that they had to work 12 and 13 hours a day to make a week's work. The resolution was unanimously carried. Mr. E. Elger moved, "That owing to the great disadvantages under which we labour, and the many evils existing in the cabinet trade, this meeting pledges itself to use its best endeavours to better their position by strengthening the ranks of unionism, and promoting a thorough union of the workers in the cabinet trade." Mr. W. Clarkson seconded the motion, which was carried. It was resolved to hold a delegate meeting, and the proceedings closed.

THE ACTION OF WATER UPON LEAD PIPES.

DR. W. SEDGWICK SAUNDERS, the medical officer of health for the City of London, has translated from the French of M. Belgrand, a pamphlet on the action of water on lead pipes, and presented it to the City Commissioners of Sewers at their meeting on Tuesday last. Having traced the employment of lead conduit pipes from the time of the construction of the first Roman aqueduct in the year of Rome, 412, the writer says: "Only within the last few years an attempt has been made to alarm the public, by endeavouring to show that the use of lead pipes is dangerous; the water, it is said, is impregnated with a small quantity of lead, which creates a slow, but pernicious action upon the health of the consumer. This year the 'war against lead,' the name given to this crusade, has made great development, and caused considerable uneasiness in the minds of Parisians." After giving particulars of a series of experiments undertaken in conjunction with M. Felix le Blanc, a distinguished chemist and gas examiner, M. Belgrand, continues: "Upon the whole, there is absolutely no danger of poisoning from the use of water flowing through leaden pipes. It would, doubtless, be very difficult to compel, as has been suggested, the Parisian householders to replace the 1,500 kilometres of lead branches at present existing in their property, since it is found that the interior of the pipes is perfectly smooth, without a trace of injury, and coated with a thin crust of adherent deposit, which prevents the contact of the lead with the water. I do not think that any other mode of distributing water can be recommended, even to nervous people; the iron pipes so much used in London, owing to their low price, are less suitable for Paris, first, because the necessary pipes and connecting pieces are not to be found in commerce, but especially as accidents from frost, more to be feared in Paris than in London, are more formidable with iron pipes than with lead." Dr. Saunders, in his preface, takes exception to one of the author's suggestions, saying:—"I object to the lining of one metal with another, such as tin upon lead, as proposed by M. Belgrand, for two reasons: first, because when different metals are brought into contact a galvanic action is set up; second,

because block-tin pipes have been known to have been eaten through by water in consequence of the presence of nitrates (De Channont)."

ORNAMENT.

MR. H. H. STATHAM lectured to the members of the Birmingham and Midland Institute on Monday night, in the new lecture theatre, on "Ornament." He said they were living in a time when a great deal of attention was paid to the ornament and decoration of their houses, and it was worth while to consider what they meant by ornament—whether there were any principles of better or worse, right or wrong, in connection with it. He defined ornament as an artistic design, which was added to some other object in order to give fresh interest or beauty to that object. That was an important point, because ornament being an art, which was always relative to the object to which it was applied, its suitability to its position and to the object to which it was applied, was a very important factor in deciding whether they should approve of it or not. The various forms which were made use of in ornament, all fell into two divisions in their application—the first being what he called surface ornament, or ornament which was employed to diversify a surface which would otherwise be bald and uninteresting; and secondly, what he called functional ornament, which was ornament so applied as to emphasise and bring out the various parts of the subject. There were also two other divisions of ornament—viz., abstract ornament, or all forms which did not imitate any object in nature, but were simply ornamental forms; and natural ornament, or that which was founded upon the imitation of natural forms. All ornament, to have a right to rank as such, must show evidence that it was intended for the position which it occupied. He showed that the essential features of abstract ornament were the repetition and alternation of different forms. With reference to natural ornament, he said if they wished to use natural forms they must not copy nature merely, but must use the natural forms in such a way as to bring them into harmony with the artificial position in which they meant to place them, and the material in which they were used. He deprecated the imitation of the human figure for architectural ornamentation, but for grotesque effects he considered that some forms of animals were permissible. He thought it was important for them to seriously consider the question of ornament, and one of his reasons was that a proper understanding of what was in good and bad taste in this matter meant a habit of applying the mind to the fitness and the unfitness of things. In many things the English were stronger than other nations; but as a nation the English were remarkably deficient in the perception of what was vaguely called taste.

LONGLEAT.

GREAT preparations are being made at Longleat, the magnificent seat of the Marquis of Bath, for the approaching visit on the 6th December, of the Prince of Wales. About eight years ago the renovation of some of the principal rooms was commenced. They are now nearly completed; they consist of drawing-room, saloon, upper and lower dining-rooms, billiard-room, library, and ante-library, (the latter will be finished next year). These rooms have all been completely stripped, and restored in a very elaborate manner. The new ceilings are all very rich in design, painting, and gilding, chiefly mythological subjects. The drawing-room walls are hung with old rich brocade silk, surmounted with a fine old painted frieze, about 3ft. deep, and very rich ceiling and cornice. The door architraves are of old Indian marble inlaid with cornelian and other stones, and capped with dove marble. The saloon has a massive marble chimney piece (about 6 tons weight) Italian alabaster architraves to the doors, and the walls hung with rich tapestry and velvet. The upper dining-room walls are covered with old stumped and gilded leather, surmounted with a painted frieze, and richly panelled and painted ceiling and cornice. The door architraves of black marble, doors, shutters, and dado of oak enriched with painted decorations of fruit, &c. The chimney-pieces have exquisitely carved

caryatides, &c., the entablatures being relieved with gilding. The lower dining-room is refitted with the old oak panelling and pictures, and has a richly panelled ceiling, frieze, and cornice. The billiard-room walls are hung with rich brown brocade silk. The door architraves of very richly carved marble. The doors, shutters, soffits, and backs and elbows are of Italian walnut richly inlaid with olive. Ceiling richly panelled, painted and gilded. The new library, (which was formerly the drawing-room) has a very rich ceiling, doors, shutters, &c., same as billiard-room with walnut architraves, &c. Book-cases in walnut inlaid with olive, carved cornice and capitals, &c. The wall spaces between book-cases, doors, windows, &c., are filled in with walnut panelling. The ante-library will be finished next year in a similar manner. Several bed-rooms have also been renovated. One has just been converted into a dressing-room for the Princess of Wales, the walls being hung with richly embroidered satin. A great deal has been done also in restoring the roofs of the mansion, and nearly all new plate glass windows inserted. The inlaid doors, shutters, carved marble architraves, and some of the chimney-pieces have been made in Venice. The decorations have been done by Messrs. Grace and Son, and the whole of the constructive and joiner's work by the estate workmen, under the able direction of Mr. W. Buckenham, who has for many years had the direction of work carried out at Longleat.

CHIPS.

The Metropolitan Board of Works will consider at their meeting to-day (Friday) a recommendation of the works committee, that the sewage reservoirs at the Crossness pumping stations and Barking outfall works be enlarged as proposed by the engineer to the board, Sir Joseph W. Bazalgette, at an estimated cost of £160,000.

An inquiry was held at Devizes on Tuesday week, before Capt. R. C. T. Hildyard, R.E., an inspector of the Local Government Board, into an application for sanction to borrow £700 on account of the waterworks. It transpired that neither the town clerk, the borough surveyor, nor members of the council had any plans or knew anything about them. The estimated cost of the works at the well was £275, whereas £623 was expended, and even then the supply was exhausted by 15 minutes' pumping. The inspector said the supply, 45,000 gallons per day, was absurdly small for a population of 7,000.

The tower of the Congregational church in Oxtou-road, Birkenhead, is about to be completed from designs by Messrs. Brattan and Son, of that town.

The parish-church of Brimscombe, near Stroud, was reopened on Thursday, the 17th inst., after restoration. Messrs. Wilson, Wilcox and Wilson, of Bath, were the architects, and Messrs. Wall and Hook, of Bisley, the contractors; the cost has been about £650.

A new block of village homes is about to be built at Whitley, Northumberland, from designs by Messrs. Dockwray and Thompson, of Newcastle-on-Tyne.

A chapel is about to be added to Whiteland's training college, Cheltenham-terrace, Chelsea, from the designs of Mr. A. J. Pilkington.

The cost of cleansing the streets of the City of London for the year ended at Michaelmas last was £22,154. The expense of paving was: asphalt, £18,647; granite, £10,853; and wood, £7,632.

The foundation-stone of a new Swedenborgian Church was laid at Soodland, near Rochester, last week. Mr. Henry Bridge is the architect and builder.

The local board of Newhaven, at their last meeting, decided to take the water supply of the town at once into their own hands, irrespective of any claims under a local and private Act of Parliament recently procured by Messrs. Lambe and Card.

A loan art and industrial exhibition is proposed to be held in Swansea, on the model of the very successful one which recently took place at Cardiff, through which £1,500 has been handed over to the free library after paying all expenses.

The engineers, contractors, and officials employed in the construction of the Leen Valley branch line of the Great Northern Railway were entertained at dinner at Linley, near Nottingham, last week, by Mr. R. Johnson, chief engineer to the company, in celebration of the completion of the undertaking. Mr. H. Lovatt was the contractor, and Mr. Madeley the brickyard manager. Mr. H. W. Sadler acted as chief local engineer to the company.

ST. AUGUSTINE'S CHURCH, CROYDON.—TWO THATCHED MEDIEVAL BUILDINGS.—DETAILS OF INNER TEMPLE LIBRARY.—CHISWICK SCHOOL OF ART.—"FONTHILL," HENLEY-ON-THAMES.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. AUGUSTINE'S CHURCH, CROYDON.

THIS church is to be built in a new district which has grown up on the south side of the town. It will stand well on the slope of a hill by the side of the Brighton-road. It has been designed on the model of some of the old churches of Surrey and Sussex, and like many of them, will depend for its effect more on its grouping and quiet colouring than on any richness of detail. The materials will be flint, with a proportion of Bargate-stone, Box-stone being used for dressings. Internally, the church will be faced with chalk ashlar. Its chief feature is the central tower, and it has been the architect's object to design this so as to be no obstruction internally. It will be carried by columns of hard Portland stone of no very great diameter, great attention being of course paid to the construction of the arches connected with it. The part to be built at once includes the chancel with its aisles and vestries, which are below, the tower, and the two transepts. The contract has been let to Mr. Carruthers, of Reigate, the amount being £5,258. The architect is Mr. J. Oldrid Scott.

TWO THATCHED MEDIEVAL BUILDINGS.

IN connection with the correspondence in our Intercommunication columns during the last few weeks, the drawings which we give to-day will be found of interest, as giving two original examples of thatched roofs to Medieval buildings of architectural importance. The first, from Norfolk, is Edington Church, a building specially inquired about by one writer and referred to by Mr. T. Drew, R.H.A., of Dublin. This picturesque structure has a western tower of much character and usually classified with the round towers of the county. It is, however, octagon above the ringing-floor level, with groining of rough carr-stone like that used at Witlow Church, close by, which building also has a tower of circular plan. The interior is enriched by a wood Decorated-period screen in the chancel of Geometric character, with shafts and caps. The chancel is low and small in design, though large enough, perhaps, for the church; it is, however, by no means well kept, not to say dirty. The hour-glass bracket on the Jacobean pulpit is original and figures on our sheet. The church stands away from the road in some fields on the top of a small eminence, and has a churchyard overgrown with furze and heather which, with the Scotch firs on the west, add to the picturesque, though barely sacred, character of the place. The other example is taken from the West of England, and illustrates the unique little 14th-century dwelling or fish-house, at Meare, in Somerset. This is certainly

well described as "a most interesting architectural curiosity." It originally consisted of two floors, the upper story being reached by an external staircase, as seen in our sketch, the upper apartments being provided with windows of good tracery and moulded arches and jambs. The ground-floor, doubtless, was used for fishing-tackle and stores incidental to the uses of fishermen, and it is said, the men for whom the building was erected, and by whom it was occupied, worked in connection with the Abbey of Glastonbury, for the purposes of supplying fish from the Abbey ponds, situated north of Meare, and adjoining the Brue. The fish-house has an open timbered roof, which is kept in repair by the proprietor, Sir Charles Taylor. The solid oak and carved alms-box, which we give, is from the vestry of Meare Church, where some armour and other curiosities are preserved. The Manor, or Abbot's house at Meare, said to have been built by Adam de Sodbury, in the reign of Edward III., adjoins the church, and is used as a residence for the farmer renting the grounds of the parish. The ancient kitchen and hall are well preserved, and two sides of the quadrangle remain. The western wing contains the hall, and is nearly perfect. The hall occupies the first floor, and is 60ft. long by 22ft. wide. The traceried windows are admirable examples of Decorated work of the best period, and the hooded fireplace is a very good example, as will be seen by our drawing. The fireplace in the kitchen is a good plain one of large size. The kitchen opens directly from the entrance-porch in a curious way. The sketches, which we publish herewith, are by Mr. Maurice B. Adams—some of the particulars of the fireplace being taken at the same time by Mr. W. Talbot Brown.

INNER TEMPLE LIBRARY.

WE gave a view, plans, and some details with a description of the Inner Temple Library in the BUILDING NEWS for Nov. 11th, and to-day we complete our illustrations by publishing a detailed sheet, giving the main portion of the entrance front to a large scale, and including some particulars of the ironwork to the gateway. Mr. R. W. Edis, F.S.A., is the architect from whose designs the work has been executed.

CHISWICK SCHOOL OF ART.

THIS new school of art, which has recently been erected at Bedford Park, Chiswick, from the designs of Mr. Maurice B. Adams, A.R.I.B.A., architect, was opened on Saturday last. The style of the facade is in harmony with the houses and other public buildings on the estate, but a distinctive character has been aimed at as the outcome of the purposes for which the school has been erected. Red brick is exclusively employed, and green slates cover the roofs. The present building is intended as only part of the ultimate whole, and has been arranged on plan with this view. It consists now of four studios, each about 32ft. by 20ft., and divided by an entrance hall and staircase, those on the upper floor communicating by arched openings through a centre small studio or painting-room. An office is placed within the entrance lobby, so as to command the doorways on all sides, and thus a screen is formed between the entrance archway and hall. This screen is in pitch-pine like the staircase, which is painted in clear peacock blue colour, and glazed with a dull varnish. The treads, which are 5ft. wide, are in teak; the school-fittings, donkey-stools, presses, desks, &c., &c., all wrought in pitch-pine, were made by Messrs. Robertson, of Alnwick, who also made the large balanced black-board and lecturer's gallery. The heating throughout, excepting in the directors' room, is by means of hot-water pipes. The lighting and ventilation arrangements were carried out by Mr. T. Elsley, of Great Portland-street, from plans supplied by the architect. The walls inside are tinted in brick-reds and grass greens, the woodwork being coloured in similar tints to harmonise. The shutters to the first-floor windows are for the purpose of concentrating the light, and these are painted in party colours after the Dutch fashion. The basements are by Messrs. Burt and Potts, and open inwards. Mr. E. S. Burchett, of the South Kensington Schools, and Mr. F. Hamilton Jackson, late of the Slade Schools, are the art masters. A north light is secured to all the class-rooms throughout the building.

"FONTHILL," HENLEY-ON-THAMES.

THIS small house has been erected and completed by Messrs. Braid and Co., from the designs of Messrs. J. and J. Belcher, of 5 Adelaide-place, E.C., for the small sum of £1,625. It consists of basement, under part, ground-floor, and offices as shown on sketch plans, and six bedrooms on first floor with bath-room, w.c.'s, and housemaid's closet and sink, &c., and two good rooms in roof. The drawing represents entrance-front from the roadway, the principal facade overlooking, from the side of a hill, the Thames and valley.

COMPETITIONS.

BIRKENHEAD.—It has been decided to extend the time named for sending in the competitive sketch designs for the New Town Hall competition from the 31st December next to the 22nd January, 1882, at twelve o'clock at noon.

HINDLEY.—A special meeting of the Hindley Local Board was held on Wednesday, the 26th ult. It was resolved that the sewerage system which should be adopted by the board should be that of filtration, with precipitation if necessary, and that the deciding of any scheme should not bind the board to carry out that particular scheme. The sewerage schemes which had been invited to be sent in, and which numbered 10, were then carefully examined, and it was decided that the premium offered, £60, be awarded to the author of plan No. 7, under the motto "Health," but that the board do not bind themselves to carry out the scheme. The following were the authors: No. 1, "Indicator," by Henry Bancroft, Manchester; No. 2, "Non Nobis Solus," by Winstanley and Ashworth, Manchester; No. 3, "Simplicity," by James Lomax, Bolton; No. 4, "Complete," by Gottle and Beesley, London; No. 5, "Endymion," by J. S. Caldwell, Hindley; No. 6, "Simplicitas et Utilitas," by Newton and Smith, Manchester; No. 7, "Health," by T. and J. H. Nuttall, Bury, Lancashire; No. 8, "Salus Populi," by George Heaton, Wigan; No. 9, "1881," by J. F. Tyler, Parbold; No. 10, "Practical Experience," by Goodison, Atkinson, and Forde, Liverpool. It was decided to send the plan "Health" to the Ince Local Board for inspection. A letter was read from the Ince Local Board asking for more detailed information than was given on the plans, but the clerk said that he sent all the plans they had to Ince. Messrs. T. and J. H. Nuttall, Bury, sent a communication tendering their thanks to the members of the board for awarding them the premium, and asking if the board were inclined to allow the scheme to be placed in their hands, &c. The letter was ordered to be acknowledged.

PHILADELPHIA, U.S.—The committee have awarded the first prize of one thousand dollars, for the proposed "Meade Memorial," to Mr. Alexander Milne Calder, sculptor, of that city. The model is an equestrian statue of the general in uniform. The horse is superbly modelled, and the figure full of graceful repose. Mr. Calder, who is a native of Aberdeen, is at present engaged upon the sculpture of the new public buildings at Philadelphia.

CHIPS.

At Tuesday's meeting of the City Commissioners of Sewers, it was resolved to consider a report by Col. Haywood, the engineer to the commission, prepared two months since, as to the cost of constructing the uncompleted moiety of Arthur-street East, from Padding-lane to St. Mary-at-Hill, so as to afford a new approach from London Bridge to Billingsgate. In the course of the discussion, Mr. J. S. Scott, commented on the extraordinary difference of the estimates for this work. Thirteen years ago an estimate was given of £88,000. Mr. Horace Jones, the City architect, proceeding on exactly the same lines, made the cost £526,000, and the City engineer had reported it as £336,000, whereas Mr. Scott said he did not believe it would exceed £200,000.

A new wing, containing schoolrooms and dormitories for 28 boys, has just been added to the Brentford district schools at North Hyde. They are built of malms brickwork, and consist of four schoolrooms on the ground-floor, each about 22ft. by 50ft., and accommodating 72 boys; and on the first and second floors, four dormitories, each 22ft. 9in. by 50ft., bedded for 36 boys. The architect was Mr. E. Monson, jun., of Acton.

SIR HENRY THOMPSON ON ART.

ON Wednesday evening the distribution of prizes to the successful students of the City School of Art took place in the School-Hall, Skinner-street, Bishopsgate. The Rev. W. Rogers, in opening the proceedings, referred to the history of the institution, which originated in 1842 in connection with the silk-weaving industry of Spitalfields; and was the first school of art founded in London. It had been removed, and had enjoyed a home in Skinner-street Schools for 15 years; and now arrangements had been made in the Common Council, for the absorption of this School of Art in the City and Guilds of London Institute, with a view to its further development and usefulness.—The honorary secretary, the Rev. R. H. Hadden, then read the annual report, which showed that the number of students had increased; and the prizes were presented to their recipients by Miss Thompson. The Science and Art Department, several of the civic guilds, the Baroness Rothschild, the committee, and others were the donors of the rewards. One prize, gained in national competition for painting groups from nature, was taken by Maria Adams. This ceremony concluded, Sir Henry Thompson addressed the students, and, after a reference to the career of the school, dwelt upon the office of art in the improvement of workmanship, and noted how enormously art enhanced the value of common things. He said art made the difference between a carpenter and a carver in wood, or a mason and a sculptor. The question of exports and imports was in the air, so to speak; but he would not go into that question, except to say that we had been exporting enormous quantities of raw material on which the profits were small, but which might assume great value in association with art-work. In illustration, he pointed out that a farthing's worth of iron would furnish material for several 5s. watch mainsprings; a pound or two of wool, with a little camel's hair, would make an Indian shawl worth 100 guineas; and a little clay, with a few other small materials might be made worth its weight in gold. The workman became a true artisan by the application of art to his labour. Art, however, should be cultivated for its own sake, as well as for its value in industries. The multiplication in recent years of art galleries and of artists was almost appalling; and one was prone to ask, how on earth are we to find new subjects? His advice to artists under these circumstances was that, more than ever, they should seek their inspiration entirely and directly from nature. Let them admire the works of the masters, but they would do little if they merely copied. (Hear, hear.) The slavish imitations of M. Angelo and of Raphael produced a deterioration of the painting of the world in the age that followed, as men neglected the sources of inspiration of those great artists. It might be asked how one could go to nature in this murky city. He thought there were many charming corners in this city. There were few places better for the artist than the banks of Old Thames; and he had seen from the Adelphi effects on the Thames such as our watery climate gave, and such as rivalled many a scene in Venice. Each should look at nature for himself or herself. It was the brain that saw. The eye was the outcome of the brain, and as much an optical instrument as his spectacles. The best brain and eyes made the best picture. "Still life" was an attractive department of painting, and its charm arose from colour combinations and the association of ideas—or, in other words, poetry. An old boot was, for instance, a fine subject. A new boot would be a detestable subject, for that it never had any associations with humanity. A pair of old squire's boots, say with a riding-whip athwart them, called up multifarious associations of the hunting-field—a fine morning, red-coats on horseback, the "tally ho," and "the death." Had he his time over again, he should go more to nature and less to art.

ON THE DECORATION OF WALL-SURFACING.

THE one way in which *not* to subdivide the walls of a room, writes Mr. Lewis F. Day, in the *Furniture Gazette*, is into two equal parts; but in the hands of an artist even such a device

may result in a satisfactory effect. An example of this is to be found in the court-room of what is now the Palais de Justice at Bruges, where the upper half of the walls, panelled in oak, is just about equal in extent to the lower half, which is hung with tapestry. The success of this dangerous experiment is probably due to the fact that the tapestry (an admirable modern reproduction of the original old work) is in marked contrast to the woodwork, and is made in a way complete in itself by a bold cornice surmounting it, whilst the upper wall is of the same material and colour as the panelled ceiling, and falls in with it; so that one compares, not the two equal halves of the wall-surface, but the tapestry with the oak—that is to say, the lower half of the walls with the upper walls and ceiling—losing sight of the fact that the wall is really cut in half. And if the spectator does not observe the fact, but only the satisfactory effect, surely the artist has proved himself an artist.

In the days when oak panelling was in vogue, it was no uncommon thing to break up the whole of the walls with panelling more or less elaborate in design; and this was often very successful in effect, although, perhaps, on the whole, less so than when a broad band was left above it to be painted or covered with tapestry. There was, at all events, less monotony in such a device, which also led the way to a lighter treatment of the ceiling.

An interesting example of a panelled room exists at the Château de Blois. The chamber known as that of Catherine de Medici, is panelled from skirting to cornice in narrow panels, all of the same size, about three times as high as they are wide, the stiles between (taken together with the mouldings) being about equal in width to the width of the panels. There are four rows of these tall panels one above the other; and it is worth noting that the three uppermost rows are carved with graceful arabesques of most varied designs, whilst the lowermost tier of panels is decorated in the simplest and most rigid fashion.

The wood-panelled walls of the rooms built about the time of Queen Anne were sometimes admirably designed, if one looked at the panels simply in relation to the proportions of the wall; but they seldom allowed for the furniture which was to come; and very often there was no furnishing such a room without disturbing that symmetrical arrangement of panelling, whilst the decoration of such large panels, partly hidden by furniture, partly in such prominence as distinctly to deserve ornamentation, is as difficult a problem as ever the house-decorator is called upon to solve. It might safely be laid down as a rule of design that the walls against which furniture is to be placed, should never be so elaborately decorated that one is tempted to regret that portion of them which is hidden by it.

A still more serious consideration in the decoration of a room than the furniture are pictures. Upon them must depend the whole scheme of decoration. Are there to be pictures or not? What are they? and how many of them? Wherever they occur, the walls must be simply a background to them, and no decoration is to be tolerated which is in the least detrimental to their effect—all of which is a further reason for dividing the walls horizontally, so that the dull colours that best set off the paintings may not be carried up to the cornice, but may, on the contrary, be relieved by a gayer and lighter treatment, which, yet not coming immediately in contact with the pictures, does them no hurt whatever.

Perfect decoration must, of course, be designed to fit the room, and every constructional feature must be taken into account by the designer; and, equally of course, the constructor should, by rights, bear always in mind the ultimate decoration of the building. But, whether owing to the exigencies of economy, of taste, or of convenience, or to whatever cause it may be due, it is in practice often impossible for the decorator to hit upon any scheme of design which shall fit in in every particular with the constructional features with which he has to deal, these having, apparently, been put together without any coherent plan. All one can usually do in such cases is to recognise the more important features of construction, and to ignore the minor ones; but there will always be a sense of dissatisfaction with the design when the eye falls upon these irreconcilable features.

Building Intelligence.

ALTON.—A new spire and tower have been added to All Saints' Church, Alton, at a cost of £780. The walls of the tower are of Selborne-stone, with horizontal bands of rough flints introduced, and dressings of Bath-stone. The terminations of the labels of all the windows have been carved with the heads of saints by Mr. Gomm, of Blackwater. The spire is covered with pressed Broseley tiles, which are fastened to the coating of boards by galvanised nails. Mr. F. C. Dyer, of London, was the architect, and the work has been executed by Messrs. J. H. and E. Dyer.

BURTON-ON-TRENT.—A new brewery has just been completed at Burton-on-Trent, for Mr. T. Sykes, of Liverpool. It is erected upon land belonging to the Marquis of Anglesea, near the Midland Railway, upon the south side of the town, and comprises, in addition to the complete brewery buildings, the necessary stores, stables, &c., together with roads and boundary-walls. The contractors for the building have been Messrs. T. Lowe and Sons. Mr. J. Stanyon has acted as clerk of works. The whole work has been carried out from the designs and under the superintendence of Mr. J. B. Everard, C.E., of Leicester.

COCKERMOUTH.—Christ Church, Cockermouth, was opened on Sunday last, after being closed for four weeks, for the purpose of cleaning and decorating the interior. The chancel ceiling has been distempered a rich blue, with gilt stars of various sizes. The timbers are coloured with a light pink picked out with various tints of the same colour. A neat design is stencilled on the under side of all the rafters in vermilion. Round the chancel walls is a dado in deep chocolate with black base. On the top is a very effective stencilled rail in vermilion, with stencilled tiles in buff. Above the chancel arch is a large Maltese cross, in the centre of which is the sacred monogram on a gold ground; the spandrels of the arch are diapered on a light blue ground, the fleur-de-lis and a cross alternately. Mr. Dobie, decorator, of Cockermouth, had the contract. The work has been carried out from designs of Mr. W. C. Jennings, architect, Cockermouth.

LONDON.—The church of St. Thomas, Charterhouse, Goswell-road, was reopened on Thursday last. The building, which was in a dilapidated condition, has been thoroughly repaired, and the whole of the interior has been artistically decorated. An ornamental tile pavement in the chancel and sanctuary takes the place of the old deal floor. The chancel is fitted with new stalls for clergy and choir, and new screen, the compartments of the latter being filled with open tracery, as well as the fronts of choir-desks. The lower part of sanctuary walls has been panelled, and a new altar has been provided. All the new woodwork is of pitch pine. The seats in nave have been entirely rearranged, so as to form proper passages, and new vestries have been made at west end of church for clergy and choir. The work has been executed by Messrs. John Allen and Sons, of 24, Kilburn Park-road, Kilburn, from the designs, and under the superintendence, of Messrs. Medland and Powell, architects, Rolls-chambers, 89, Chancery-lane, W.C.

LOSTWITHIEL.—A new Wesleyan chapel was opened at Lostwithiel last week. It is in the Gothic style. On the east side of the chapel there is a schoolroom, which opens into the chapel at the further corner, and at the intersection of the roof of the schoolroom and the roof of the chapel there is a tower with spire. The tower is in three stages, and the steeple is of Bath stone, surmounted by a vane. The quoins and dressings are granite, and the walls are of Derrycombe stone. The walls and roof are plastered internally. The roof is Gothic in form, with moulded cornice and ribs. At the end, and above the rostrum, a moulded arch opens out an organ and choir gallery, at the back of which is a rose window. Mr. James Hicks, of Redruth, was the architect; Mr. Philp, of Lostwithiel, was the builder; and Mr. Brown, of Lostwithiel, the mason.

NEWCASTLE-ON-TYNE.—St. Mary's Catholic Cathedral, Clayton-street, Newcastle, after being restored and decorated, was reopened last

Sunday. The restoration consisted of new flooring, newly varnished seats, and renovation of the stonework, executed by Mr. John Foggin, contractor, Newcastle, and painting and decorations by the firm of Lavers, Barraud, and Westlake, of Endell-street, London, W.C. The decorations are of the fifteenth century period of art. The nave-roof has been painted red and buff, with decoration on the main timbers. A border in light red, on buff, runs over the arches, terminating at the top of each column, with a crowned M under a small canopy. The aisle-roofs are painted buff, with the timber a neutral green. The Litany of the Blessed Virgin is written upon scrolls in the nave, and upon a ribbon under the wall-plate in the aisles. Borders have been painted round the windows, and pictures of the Stations of the Cross by Mr. Westlake are to be placed under canopies between each window. The chancel-roof timbers are of light red, with buff ornament, the chambers of buff and black, and the front member of rafters bear a number of fleurs-de-lis in gold. The panels are diapered with quatrefoils in grey, the centre of which contains a gold star and fleur-de-lis alternately. The walls of the chancel have borders in green over the arches, and they have been diapered with a rose and lily, each having the inscription beneath, "Ave Maria." The figures of the Blessed Virgin and St. Gabriel under canopies, representing the Annunciation, have been painted by Mr. Westlake. There are also four figures of angels under canopies, holding scrolls with inscriptions from the first part of the Litany of the Blessed Virgin. The whole of the work has been executed under the supervision of Messrs. Dunn and Hanson, architects, of London and Newcastle.—All Saints' Church, Newcastle, was reopened on Wednesday. The building has been repointed throughout; the parapet partially rebuilt and strengthened in the other parts; the roof reslated; the steps at the main entrance, side entrance, and approaches are new and intersticed with cement. As to the interior of the church, the old flagging of the portico has disappeared, and in its place is an artistic concrete cement floor with various coloured bands, by Messrs. W. B. Wilkinson and Co., to whom the cement-work in portico, aisles, morning chapel and approaches was entrusted. The great feature of the internal restoration lies, however, in the decorations which have been introduced, executed by Messrs. Adam Robertson and Son, of Newcastle and Alnwick. The entire work of restoration has been entrusted to and carried out under the direction of Mr. Thomas Reay, Grey-street.

NEWNHAM.—The restoration of Newnham Church was effected six years since, but early this year, the 27th of February, the church was nearly destroyed by fire. Plans prepared by Messrs. Waller were approved, the work was given to Mr. A. King, of Gloucester, by whom the destroyed church had been restored, and in a little over the six months which have since elapsed the church has been substantially re-erected and completed on the former lines. Nothing of the original church remains except the two lower stages of the tower, the north porch, and the 11th-century font. The preservation of the porch is due to the thick internal doors of oak, which resisted the flames. Externally the church presents a good appearance. The roofs are covered with Broseley tiles. The pulpit has been entirely executed, under the supervision of the architects, by Mr. Henry Frith, of Gloucester, who has also done the stone-carving in the other parts of the church, and the wood-carving of the bosses to the roofs. The decoration of the chancel was carried out by Mr. Hyett, of Gloucester.

WARMINSTER.—Christ Church, Warminster, which has been closed for some time for extensive alterations, was reopened last week. The west gallery has been pulled down, and the old lobbies beneath have also been taken away. The ceiling has been removed, leaving a lofty open-timbered roof. Two rows of Bath stone arches have been thrown up to support the edifice, making a lofty and well proportioned nave with aisles. The chancel arch has been elevated, and considerably embellished. The old sittings have been entirely removed, and have been replaced by low seats of pine wood. The decoration of the walls is not yet complete. Mr. Vids, of London, has been the architect, and Mr. J. Gilbert, of Warminster, the

contractor; Mr. John Ponton, having been the sub-contractor for masonry, &c., and Mr. Grant for plastering and colouring. The carved work in wood and stone was done by Mr. Harry Hems, of Exeter. The beams of the roof were stained by Mr. Luke, and the seats by Mr. Edwards. Mr. R. R. White executed the gas-fitting.

WESTMINSTER ABBEY.—The restoration of the three portals of the north transept of Westminster Abbey outside the principal entrance in St. Margaret's Churchyard, the total cost of which amounts to about £20,000, are now completed, with the exception of a few minor details in connection with the central portal. The restoration have been executed from the designs of the late Sir Gilbert Scott, and the work has been carried out by his son, Mr. John Oldrid Scott. The elaborate carved work on the eastern, western, and central portals is of the Early English type of the reign of Henry III. The sculptured figures, which have been executed by Mr. Brindley, of Westminster Bridge-road, embrace on the arch to the left the Patriarchs from Adam to Solomon, and on the right all the Major and Minor Prophets. In the central portal is a life-size figure of Christ in a halo of glory, surrounded by the emblems of the Apostles, and beneath, on the two panels, are represented a series of incidents in the life of Christ. Above and round the arches are the figures of a number of angels playing on various musical instruments, and erected at the base are the life-size figures of the Twelve Apostles. Care has been taken in the present restorations to use a durable stone from the quarries of Chilmark, near Salisbury.

CHIPS.

The members of the Oxford Architectural and Historical Society, in their last Saturday round of visits, went to St. Edmund Hall, said to have been founded by Saint Edmund le Riche, and to St. Peter's-in-the-East, the earliest facts of which date from the reign of Henry II. On Tuesday evening last an evening meeting was held at the new museum, when a paper on "Windsor Castle" was read by Mr. Parker.

For the first time since the establishment of the Ipswich School of Science and Art a local prize fund has been provided, in addition to the medals and prizes offered by the Government department at South Kensington, the sum of fifty pounds having been subscribed for that purpose by gentlemen in the town and neighbourhood.

A new Congregational Chapel was opened at Turnham Green on Wednesday week. It seats 450 persons, is Gothic in style, and cost £3,400. It has been built from the plans of Mr. T. Lewis Banks, A.R.I.B.A., of Finsbury Circus. The contractor was Mr. Thomas Brunsden, of Watford.

The foundation-stone of a new church at Fynnongroew, near Llanasa, was laid last week by Lord Mostyn. The church will seat 300 persons, and will cost about £1,300.

The Nottingham School-board, last week, appointed the following as architects for new schools about to be built at Dab-park, Radford, and elsewhere, subject to their design meeting the approval of the board:—Mr. A. N. Bromley, Messrs. Evans and Jolley, Mr. A. H. Goodall, and Mr. George Hine.

An extensive range of stabling has just been completed for Mr. Meek, at Cross-Deep, Richmond. They are Classic in style, and are constructed of white facing bricks, with Box Ground-stone dressings and a Portland-stone central pediment; inside they are faced with Cliff's white-glazed bricks, above a plinth of coloured bricks. In the central pediment is a clock by Messrs. Gilet and Blind, of Croydon, and above it a turret, containing three bells. A gardener's cottage and other buildings have been carried out in harmony with the stables. Messrs. Crickmay and Son, of Westminster and Weymouth, were the architects, and Mr. Messon, of Twickenham, was the builder.

A three-light Perpendicular window in the south aisle of Southover Church, East Sussex, has just been restored at the cost of the lord of the manor. Mr. C. F. Badgman, of Lewes, carried out the work.

The town wharf at Maidstone is being extended by 100 ft., and the levels throughout will be altered. The contract has been taken of the local board by Mr. H. Towsley.

It has been decided to restore the nave of the Early Norman church of Manningford Bruce, from plans prepared by Mr. J. Loughborough Pearson, R.A. The estimated outlay is about £1,500.

ARCHITECTURAL & ARCHAEOLOGICAL SOCIETIES.

BRITISH ARCHAEOLOGICAL ASSOCIATION.—The first meeting of the session 1881-82 was held on Wednesday week, the Rev. S. M. Mayhew in the chair. The discovery of a Roman Villa, evidently of considerable extent, at Wingham, Kent, was announced. Aided by a grant from the Kent Society, the villa is being excavated by Mr. Dowker, and already three rooms with tessellated pavements, have been uncovered, while the fourth has a hypocaust. The work is very fine, the walls in one room being lined with mosaics. Funds are much needed for the prosecution of the researches. Mr. Loftus Brock, F.S.A., also reported the efforts made by the Association with respect to the safety of Stonehenge since the meeting there last year, and read a letter from Sir Ed. Aubrey, the owner, who disclaimed all intention of "restoration" in the works undertaken there by him. There are but for the safety alike of the monument and the visitors. Nothing permanent will be done until the spring. In the discussion which followed several speakers referred to the somewhat unfair remarks that have been made with respect to the intentions of Sir Ed. Aubrey, whose efforts to uphold Stonehenge deserve thanks from antiquaries. Mr. Way exhibited some medieval pottery from Southwark, the Rev. S. Maude a unique denarius of Gallienus with the name of Germanicus on the reverse, and Mr. R. Soames a drawing of remarkable sculpture in Brixworth Church. It is called an eagle, and is supposed to have been brought from the Roman Villa which existed close to the building, where it is now built into one of the walls. Mr. G. R. Wright, F.S.A., exhibited some drawings of Mulgrave Castle, Yorkshire, and described some of its curious windows. The first paper was on the Bourg ez Zifair, Cairo, by Professor Hayter Lewis, F.S.A. This is one of the angle bastions of the wall of Cairo, now almost covered by sand. It has an octagonal central chamber 26 ft. in diameter formed of neatly cut stone. It dates, probably, from the time of Saladin. Mr. J. W. Grover, F.S.A., in the discussion which followed, alluded to the appearance of the pointed arch in a developed state here, and to the magnificent Museum of Egyptian Antiquities, at Bouak. The second paper was by Mr. Gordon M. Hills, and was on the measurements of Ptolemy applied to the northern part of Britain. He identified Hornsea Lase, E. coast of Yorkshire, as Ptolemy's "Portus Sinus," and Penrith as the starting point of the 10th mer. S. 144, the second station, he placed at Gullaber, near Tebay.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—The annual report of the Birmingham Architectural Association states that the session just ended was commenced and carried on with as much average success as any previous one, but the Committee consider that each session should be more successful and more beneficial to the members than its predecessor, and, therefore, cannot regard the past session as having been entirely satisfactory. The Committee remind the members that the success of the Association, and the attainment of its chief objects, depend almost entirely upon individual activity, and that the Association will not reach the flourishing and prosperous condition in which it ought now to be, as long as such a large proportion of the ordinary members regard its interests with indifference. During the session five members resigned, and eight new members were elected. The total number of members is now forty-four, of whom twenty-nine are ordinary, and fifteen honorary. The balance shows a total income and expenditure of about £60, but is so far satisfactory that the balance against the treasurer has been reduced from £18 0s. 4d. to £12 8s. 7d. It appears that the subscriptions to the London A. A. for 1879-80 and 1880-81, in all £13, are still unpaid, but on the assets side are £10 arrears of subscriptions. The officers for the year are:—President, Jethro A. Cosins. Committee: Chairman, H. H. M. Connell. Ordinary Members of Committee: F. W. Cross, T. Jones, W. H. Kendrick, W. G. Mancl, J. P. Osborne, A. Reading, and E. Wood. Hon. Treasurer, R. B. Morgan. Hon. Librarian, O. Essex. Hon. Secretary, Fred. G. Hughes, 3, Temple-row West, Birmingham.

LIVERPOOL ARCHITECTURAL SOCIETY.—The second ordinary meeting of this Society was held

at the Royal Institution, Colquitt-street, on the evening of the 16th inst., the President, Mr. Charles Aldridge, F.R.I.B.A., in the chair. The prizes for drawings submitted at the various meetings of the class of construction and design during the last session were awarded to the successful students—the first to George Hornblower, and the second prize to Richard Holt. The paper for the evening, entitled "Recent Notes from the Continent in Pen and Pencil," was then read by the author, Sir Jamea A. Picton, J.P., F.S.A., and was illustrated by numerous sketches of features of interest at the various places visited by him. A discussion followed, in which the President, and Messrs. Boulton, Barr, and Morton took part, the meeting terminating with the customary vote of thanks to the author of the paper.

ARCHÆOLOGICAL.

ARCHÆOLOGICAL DISCOVERIES IN NEW MEXICO, UNITED STATES.—During the past two years, Major J. W. Powell, United States Ethnologist, has had several parties at work at different points in the Western States, exploring some of the pre-historic remains of the old Pueblo or house-building races. One party, in charge of Colonel James Stevenson, visited the isolated Indian tribes still inhabiting portions of New Mexico, and the collections made of objects ancient and modern are the most extensive and complete of any ever gathered together in that section. In the ancient Pueblo of Zuni the natives retain their purely aboriginal character. These people live in stone houses, piled upon each other like immense bee-hives. The Zunians manufacture a fine grade of pottery, entirely uninfused by civilization, and ornament it with designs in colours. The ruins in the vicinity are very extensive, covering hundreds of miles, and point to a former population of millions of souls. The collections made by Mr. Stevenson comprise many thousands of modern clay vessels, implements of stone, utensils and articles of clothing and of ceremony, and also a vast number of pre-historic relics from the ancient ruins. During the present year these explorations have been continued, and within the past three or four months the most important discoveries have been made. For many miles the stone bluffs of one of the canons have been found to be literally honeycombed with thousands of human habitations, now fallen to decay, and Mr. Stevenson is yet exploring them and gathering together information for future publication.

SCHOOLS OF ART.

METROPOLITAN DRAWING-CLASSES.—The annual presentation of Queen's prizes and certificates to the students attending these classes was made at the City Guildhall, on Tuesday evening, by Earl Northbrook. The Lord Mayor presided, and in opening the proceedings remarked that he had found those workmen the most valuable who devoted their evenings as the students before him had done, to the practice of mechanical drawing. Mr. W. Bushbridge, the instructor of the classes, read the annual report, which was of a very satisfactory character. During the year there had been nearly 1,000 students in the various classes, of whom 656 obtained certificates at the Government examinations last May, the latter number including 208 who gained Queen's prizes. In building construction, nearly one-fourth of the Queen's prizes awarded to the whole of the United Kingdom were obtained by students in these classes. The report added that a greater amount of liberality on the part of the Government would give such an impetus to technical education as would fit the English workmen to withstand any amount of competition with foreign labour. A resolution pledging the meeting to promote the welfare of the classes was moved by Mr. John McGregor ("Rob Roy") and seconded by Mr. Sheriff Ogg. Lord Northbrook, in distributing the prizes, referred to the inestimable advantages of technical education such as was afforded by these classes, which, he said, were doing a good, sound, practical work, which must be greatly to the advantage of the working men of the Metropolis, and ultimately to the country at large.

"To a practical man with a taste for mechanics, and the bumps of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Twopenny of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is 6s. SHILLINGS for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL., Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—W. C. H.—B. S.—B. and B.—J. W. and Co.—W. and Co.—T. W.—C. P.—W. and Son.—F. and Son.—T. E.

JAS. HUNTER. ("Plaster of Paris.")—APPRENTICE. (Write Lockwood and Co., 7, Stationers' Hall-court, for list.)

"BUILDING NEWS" DESIGNING CLUB.

RECEIVED.—Zell, Percy Thompson (there is no entrance fee. The drawings are returned after the review appears, and the same motto is used for every set of drawings sent by one competitor), Hotspur, G. E. H. (all drawings are returned).

DRAWINGS RECEIVED.—Buathorne, "I Fain would Climb, but that I Fear to Fall," Hotspur, Folle-Farig.

Correspondence.

WHY PROVINCIAL ARCHITECTS DO NOT JOIN THE R.I.B.A.

To the Editor of the BUILDING NEWS.

SIR,—At the opening meeting of "the Royal Institute of British Architects," the President, Mr. G. E. Street, R.A., said:—"There is again another class which might be more largely represented here, and this is the class of provincial architects. Some of our most distinguished members practise in the provinces, but the number of these who belong to us is very small."

One cause of this is easily explained. I know that many provincial architects, in common with myself, consider that the Institute did not treat us fairly, when some few years since they raised our subscriptions to the amount paid by the London members. The advantage of the Institute are very small indeed to provincial architects. Living at a distance from London they can but very seldom attend the meetings, or use the rooms and library—in fact, all the return for the subscription is a copy of the Transactions, and the very doubtful benefit of writing "F.R.I.B.A." after their names. I am afraid, Sir, the general public, our clients, know but little of the R.I.B.A., and give less heed to those mystic letters, for one constantly sees very inferior men, who do not use them, doing as

well, if not better, than their professional brethren who are members of the Institute, and is it not a fact that the leading members of the profession who can use the letters "R.A.," "A.R.A.," and even "F.S.A.," do not write "F.R.I.B.A." after their names, though surely the last should be deemed more honourable and appropriate than the "F.S.A." Is it that they are ashamed to use them? If the Institute really wishes provincial architects to become members, it should offer sufficient inducement and equivalent advantage.

I should rejoice to see membership of the Institute as the recognised guarantee of the status of architects; but such is not the case now. If a provincial architect is asked to join the institute he says "Cui bono?" and with reason. I know men of very good standing who laugh at the idea of seeking membership, and say, "Why should I pay a subscription to keep up a London institution which does not benefit me?"

It is a mistake to suppose that the public look upon membership of the Institute as a guarantee of professional standing, though such ought to be the case, and is in other professions.

It may be said, "It is all very well to find fault; but what do you want or propose?" Well, Sir, I would say—

1st. Go back to the old system of making the subscription of country members more in accordance with the use they can make of the Institute.

2nd. Give them a greater voice in the council.

3rd. Have provincial branches, and hold congresses and meetings in provincial towns, that the provincial public may know more of the R.I.B.A.

4th. Seek union with provincial architectural societies.

In a word, throw off the metropolitan exclusiveness of the Institute. If the much-respected and admired president, whose straightforward and vigorous address charmed us all, will set his practical mind to alter and improve the present state of things, he will confer a lasting benefit and obligation upon the profession, and that he can do so, no one more firmly believes than your obedient servant,

A PROVINCIAL ARCHITECT.

BIRKENHEAD TOWN HALL COMPETITION.

SIR,—Permit me to call your attention, and that of the referee (Mr. Barry) to a feature of the above, which I fear has not received the attention it deserves.

You are doubtless aware that the first competition is for sketches only, five of which are to be selected, and finally worked out by their authors; Clause 5 of the instructions saying, "In order to obviate the possibility of the sketch designs lodged in the preliminary competition being made use of by the competitors invited to take part in the final competition, such sketch designs will not be allowed to be seen by any one except the council and referee, and will be retained until the final competitive designs have been sent in."

This seems fair until the fact is considered that the said council contains, amongst its members, two architects, and the father of a third, all likely to be competitors, and yet in a position to see the plans sent in by others, and to make such use of their contents as they may see fit. Surely the gentlemen alluded to should not be permitted to see the sketches at all.—I am, &c., C.

PRELIMINARY COMPETITIONS.

SIR,—Is your correspondent, "A. B. C.," a professional? for his suggestions are, to say the least of them, most remarkable, as coming from such a source. His proposal is what is called in the lower ranks of betting men, "squaring the mag."

His experience is greatly different from mine if he usually finds in a large competition like the one he names that, say, out of 100 or 170 designs (which I anticipate there will be at Glasgow) there will not be ten or even six sets of plans of tolerably even merit.

The parties selecting will certainly not make such an invidious distinction as he suggests—i.e., to select them in the order of merit, say, from 1 to 10, in progressive order; and I also greatly doubt if any one of the ten will think so little of his own production as to give it, in his estimation, ought but the first rank. The author

rities have very properly forestalled any such prejudging, by refusing any exhibition or criticising in advance of the designs.

Should any of the competitors distrust his own chance, he can decline the contest, to the better chance of the remainder; and this is possibly what "A. B. C." desires.

I make a counter-proposal. Say, let the three best work out their chances without further payment or fee—for the prize is a great one—and the remaining seven retire, on being paid the total honorarium amongst them. This is no doubt an insane and unlikely proposal; but it is the very embodiment of equity, compared with "A. B. C.'s" proposal—viz., that, say, seven competitors should voluntarily sacrifice their chances for the sole and entire benefit of three men, who thus reduce the odds of 9 to 1 to 2 to 1, and are further handsomely paid for thus bettering their chances at the expense of the "scratched."—I am, &c.,
Nov. 26.

VIGILANS.

THE ADMIRALTY BUILDINGS.

SIR,—The lately-published description of the contemplated rebuilding of the Admiralty, &c., is so very circumstantial, that it appears to me there must be a design made for the same. I hope, however, this is not the case, and that there will be a public and quite open competition for the new structure. A Government which prides itself on free trade should be consistent, and let us architects have the benefit of the principle. At the present time there is remarkable slackness of work in the profession, and there never was a time in which so much talent was seeking development; and, therefore, it would be an excellent thing just now to have a good national (or international) competition. I fear a Board of Works job is imminent, however.—I am, &c.,
M.

TESTING TRAPS.

SIR,—I expected to find at the experiments conducted on Saturday a trap and w.c. fitted up as they should be under ordinary circumstances; but I was disappointed, for the bottom of the trap was 15in. below the top of the floor (when it should have been 10in.), and did not leave enough to taft over; also, instead of the water being laid on to the w.c. in a proper manner, it was supplied over the top of the basin with a rubber hose, and a dribble of water not equal to a stream, through a 2in. pipe. The consequence was (under these extreme circumstances), when Mr. P. J. Davies jerked up the handle and dropped it as if it was a hot iron instead of a w.c. handle, the trap nearly lost its seal; but, strange to relate, when another gentleman (under a strong protest from Mr. Davies, who said no one should touch the handle but himself), lifted the handle and dropped it in the ordinary manner, the trap had a proper seal.

Now, I contend (what has been proved in hundreds of cases), that if a ∇ -trap is fixed under a valve w.c. close up to the floor, as it should be, with a 2in. airpipe, and a proper regulated supply of water to the w.c., it is an impossibility for it to lose its seal. I admit the water does pass through the trap with such a velocity that it thoroughly secures it and the soil-pipe too, and sometimes displaces some of the water in the trap, yet if fixed under ordinary circumstances the water supply always makes up the deficiency. If a trap is not fixed as under usual conditions, what is the value of the test?—I am, &c.,
J. W. HART.

21, Dorset-road, Clapham-road, Nov. 21.

SIR,—I take the castigation of your correspondents, together with your foot-note, and promise to be more careful in future. Fortunately, however, the error of 18in. instead of 11in. does not in the least affect the point at issue; 14in. being more than sufficient for the purposes of my argument.

It will help those of your readers who have not had time to study the question, to understand the points at issue better, if they will try the following simple experiments, one of which is quoted by Mr. Davies on page 510, and again in his letter upon page 608.

Place a Beard and Dent's ∇ - or half ∇ -trap upon a bench, fit to it an improved hopper-basin and charge the trap; then place into the basin a closet-plunger, and fill it with water. Now remove the plunger, and you will find the trap unsealed—it has momentually out. Repeat the experiment, but, this time, hold against the front of the outgo, about an inch down from the top, a piece of wood; you will now find the trap will not unseat, simply because the piece of wood has resisted the momentum.

Now, in the place of the ∇ - or half ∇ -trap, fix a Dubois or Sutcliffe ∇ -trap, with basin, &c., as before: repeat the first experiment, and you will find the seal scarcely affected, and why? Simply

because the curved form of the outgo has, like the piece of wood, resisted the momentum, and the outer leg is not long enough to cause siphonic action. Now, add 2ft. of soil-pipe to the outer leg; you will now find a considerable drag upon the seal, but not enough to unseat it—the siphonic action is not yet strong enough; add another 2ft. to outer leg and the trap will siphon out every time; then cut a hole in top of outgo, and you will again find your seal secure.

There is, however, one most important point which must not be lost sight of in carrying out these experiments, viz., the manner in which the plunger is removed from the basin. Its removal should be made to represent as nearly as possible the action of a valve-closet, this may readily be done by passing the plunger up against the sides of the basin. If, however, instead of this, the plunger is pulled through the water, an action is produced which represents nothing in practice, but which causes a vacuum into which air rushes and forces out the seal.

Now these simple experiments, which may be tried by any one in half an hour, show very clearly the difference in the action of the ∇ - and ∇ -siphons, viz.—

1st. That the ∇ is not untrapped by momentum, but by siphonage, which can be prevented by ventilation.

2nd. That the ∇ is untrapped by momentum, which cannot be prevented by ventilation, but which can be greatly checked by resistance offered at the outgo. This resistance occurs when a ∇ -trap is fixed into a long soil-pipe with a short branch; it has, however, then to contend with siphonic action as well, and it is under such circumstances that ventilation can assist it.—I am, &c.,
DANIEL EMPTAGE, S.E.

Margate, Nov. 21.

CHIPS.

An inquiry was held at West Malling, near Maidstone, on Friday, before Captain Hildyard, R.E., one of the inspectors of the Local Government Board, into an application from the rural sanitary authority for sanction to borrow £1,000 for the drainage and sewerage of West Malling. Mr. W. S. Norton produced and explained the scheme which had already been partly carried out. The inspector expressed an opinion that £1,000 would not be sufficient to complete the works, but said it would be possible to obtain a further loan.

A new Baptist school at Ebbw Vale was opened on Monday. It accommodates 250 scholars, and cost £300. Mr. Wilputte was the honorary architect, and the contract was carried out by Mr. Evan Thomas, of Ebbw Vale.

A public improvement, consisting of a wide road from the Chiswick vestry-hall to Grove-park station, has just been completed at the cost of the Duke of Devonshire. The plans were prepared by Mr. Henry Currie, surveyor to his grace, and the contract has been carried out by Messrs. Nowell and Robson, of Kensington.

At the annual meeting of the governors of University College, Bristol, held last week, it was reported that plans had been prepared for the council by their architect, Mr. Hanson, for the erection of a new wing, which would be carried out as soon as £2,000 more was subscribed in addition to the £4,500 already promised towards the cost.

The surface drainage of Teddington has just been completed under the superintendence of the surveyor to the local board. The contract has been carried out by Mr. Pillar, at a cost of about £1,900.

After having been closed some time for extension and improvement, the Leeds Library was reopened on Monday. On the north side of the principal room a large apartment has been built as a supplementary reading or writing-room. The room is lighted from the ceiling in the evening as well as by day, for after dusk the gaslight is, by an ingenious arrangement, thrown down from between two glass roofs, so as to avoid any damage to the books or discomfort to visitors from gas-fumes or excessive heat. At the end of this new room there is a smaller one, reserved for exceedingly rare works, which include the Benedictine edition of the Fathers, Nichol's "Leicester," the Domesday Book for Yorkshire, and many ancient manuscripts. The structural alterations have been carried out from the designs of Mr. Thomas Ambler, architect.

Truth says that two important conditions have been insisted upon by the Lord Chamberlain's department previous to the year's inspection of theatres:—1, the construction of a concrete wall, or partition, over the proscenium arch and between the stage and the auditorium; 2, a constant double and distinct supply of gas to the stage and to the auditorium.

Entercommunication.

QUESTIONS.

[6784.]—Extras.—In a case where an architect orders certain extra works to be done by the contractor without first obtaining the consent of his client, is that client bound to pay for such extra work, and, if not, from whom is the contract or to obtain payment?—NVRMEL.

[6785.]—Selection by Architect.—When a certain price is allowed in specification for different articles to be selected by architect, what is the ordinary custom in the profession in regard to payment for same? If the architect orders certain things and instructs the seller to make out his account, charging the same to the contractor, then the architect has no guarantee that such articles have ever been paid for, and the seller may come upon him at any time for payment as the person who ordered them. Then, again, supposing the architect pays for such articles himself at the time, does he deduct the same from the contractor's tender at the rendering of the final accounts? If so, he will not get his percentage on such payments. Besides, it occurs to me such additions to an architect's account when rendered to his client would certainly appear very unprofessional, but if not entered in his accounts how is he to obtain payment? Will an older practitioner suggest?—NVRMEL.

[6786.]—Waterworks.—Will some correspondent kindly say what head (above top of highest house) would be required to supply a town with water, having sufficient pressure to throw water from a fire-hose to the top of such house, length of main one mile, 6in. pipe, required supply 60 gallons per minute?—PRESSMAN.

[6787.]—Breaking Weight of Girder.—Kindly inform me of the formula for working out the breaking weight of a girder as per annexed sketch? Also formula

for working out the breaking weight of other girders made up in the same way, but different depths and widths?—INDUCTUS.

[6788.]—Laying Tiles in Exposed Roof.—Can any reader inform me the best way of laying the tiles in a roof in a very exposed situation?—J. L. SMITH.

[6789.]—Scantling for Tile Roof Rafter.—What is the proper scantling for a tile roof rafter of Sit. bearing at 45° pitch?—YOUNG 'US.

[6790.]—Clubs.—Will any of the readers of the B. N. kindly inform me which are considered the best arranged clubs in London, and in what works any plans of them can be seen?—SMITH.

[6791.]—Rubbings of Ornaments in Low Relief.—Can any one give practical information as to the best modes of getting impressions or "rubbings" of low relief ornament such as that on the Runie and Irish crosses, &c.? There is, of course, the old-fashioned method with heel-ball and rubbing. Is there not some improved way? What is the method called "taking a squeeze"?—Q.

[6792.]—Chancel Screen.—Is it unusual to put a Perpendicular screen into an Early English church, or is it considered the proper thing for the screen to suit the building? The church is a modern one, and its general characteristics are Early English. Have noticed that a few modern churches about here have rather a mixed style, having Perpendicular East windows, the rest being Decorated, &c. A Perpendicular screen would be preferred if not out of the ordinary way.—YORKSHIRE.

[6793.]—Luminous Powders, &c.—In Part 14, fourth series, of the Art Workman there is an article on Luminous Powders. Could any of your readers give me information as to their suitability for rendering walls or surfaces for advertising or other purposes luminous in the dark, where procured, cost, &c. 2. Similar information desired regarding luminous paint, recommended recently in the postal department for encircling the openings in wall letter-boxes when situated in dark places, and if to be had in different colours. Ditto regarding luminous wall-papers.—MAC.

[6794.]—Problem.—I should be glad of a solution of the following seemingly simple problem. I have given it to half a dozen men, and have had six different replies. A. purchases a lease of 14 years' for £1,050. The rent for the first ten years is to be £25 a year, and for the last four £300 a year. At the end of the first ten years A. agrees to sell the lease to B. at a proportionate price to what it cost him. What is the sum that B. must pay?—COCKER.

[6795.]—Memorial.—I should be grateful for your advice in the following matter:—A fund has been subscribed (£150) to raise a suitable memorial to a deceased gentleman. The question is, What form is it to assume? For one reason or another, the following are out of the question—Monument over grave, stained glass window, mural tablet in church. If we decided upon a marble bust or portrait in oil to present to his family, what class of artist could we command for the sum at our disposal? What else can you suggest?—MEMORIAL.

[6796.]—The Sanitary Institute Examination of Surveyors.—In the BUILDING NEWS of Nov. 11 is a paper of questions for the above, which I dare say not one in ten of the existing local surveyors could answer off hand; and, perhaps, there would be small practical advantage in their being able to do so, for knowledge is as available in a book of reference as carried to and fro in the brain, provided a man can bring it to bear when wanted. Nevertheless, since cramming is in the order of the day, I should be glad to know what books it would be advisable to read with a view to passing the above

examination, and also where the Sanitary Institute "hangs out."—SLEEPY SAM.

[6797].—**Villa.**—Having a country villa to design for a speculating gentleman to cost about £1,200, I shall be glad if Mr. Hugh McLachlan, "G. H. G.," or some other of your experienced correspondents will answer the following:—1. As a sea view and better land view would be obtained from the first floor, would it be advisable to put the drawing-room on that floor instead of the ground-floor? 2. Would it be best to have a service door to dining-room from pantry, or in a villa of this size would a second door take up too much room, and the ordinary door be used as service door? 3. Would it be necessary to have a cloak-room and lavatory, with w.c. attached, on the ground-floor? 4. Can you recommend me a really good and comprehensive modern book on house planning and designing?—A YOUNG ARCHITECT.

REPLIES.

[6743].—**Architect's Account.**—Though it is very unusual for a client to ask to see the complete detailed bill of extras and omissions with the builder's prices, I cannot see how an architect can refuse to show it when demanded unless on the ground that it is private and privileged and that the builder will not give his consent to the client seeing it, when the dispute might be left to the builder to settle.—HUGH McLACHLAN.

[6747].—**Thatched Churches.**—Theberton church, Suffolk, has a thatched roof, and is otherwise very interesting. In the next parish, Leiston, are the remains of the abbey, which are well worth a visit, and are still very extensive. Here cattle are stalled in the very place where the high altar stood, and no care whatever is taken of the ruins, though the stonework is beautifully moulded and carefully wrought.—T. GOODMAN, Southend-on-Sea.

[6749].—**Commonplace Book.**—In reply to the question by "L. E. K.," a few hints as to a system of my own may be of some use. Since I entered the profession, some five years ago, I have adopted the following plan:—I keep separate memorandum books for the chief points connected with architecture, as surveying, perspective, quantities, valuing, architecture generally, &c., &c., and range from book No. 1 to No. 9. I also keep an index-book separate, and when noting anything special put it down in its proper book, at the same time entering it in the index book under its proper heading; saying, see Book No. —, page —; or see BUILDING NEWS, January —, page —, or any other book, &c., &c. By this method I have entered up the "Commonplace Column," and other special pieces in the BUILDING NEWS at various times, and thus having one general reference book, I can at a moment's notice find something mine or ten pieces on the subject wanted. I have found this system to act very successfully, and can endorse Mr. "G. H. G.'s" remarks as to the benefit of keeping a commonplace book.—MAX W. BLAKELEY.

[6753].—**French Casements.**—There is nothing better than oak for the sill, English, notwithstanding its roughness of grain, to be preferred. It would require at least a dozen sketches to show what "Reader" asks for, the windows having to open both outwards and inwards, with sections of all joints; there are several methods of keeping out the weather, more or less effectual and expensive. Some casements have fixed muntins at meeting stiles, and others are without them, therefore unless it was known pretty nearly what "Reader" required, sketches might be made to little purpose. Smith's watertight casement bar may I believe be had from both Messrs. Archibald Smith and Stevens and Messrs. Smith and Turner. For fastenings use spagnolette bolts; they can be obtained from all the leading furnishing ironmongers.—HUGH McLACHLAN.

[6753].—**Measuring Brickwork.**—I believe not. With regard to measuring for labour only I am not too well versed to give an opinion; but for labour and materials in and around London, it is the rule to deduct all openings except flues and hollow walling, the last being taken and entered as a separate item in the bill.—HUGH McLACHLAN.

[6765].—**Glazed Earthenware Flue Lining.**—Is it not also liable to get cracked and broken by the heat? I have heard so; but perhaps this would only happen if the chimney caught fire.—C. F. M.

[6768].—**Fifteenth-Century Plate-Armour.**—Commencing at the crown of the head, there is the helmet, or, if it is without a visor, the basinet. Close-fitting bascinets were often ornamented by a jewelled *orle* around them. See, for instance, the effigy of Sir Richard Peyton in Tong Church, Shropshire. (The helmet or head-piece of a horse is called the chamfron or chamfraine.) The *gorget* or *gorgerie* of plate is the portion round the neck, and the epaulet-like protections to the shoulders are the *pauldrons*. Then comes the breastplate-coirass. The *ere* braces protect the upper portions of the arms, and the vambraces the lower parts. Between them the elbows are covered by the *coules* or elbow-plates. On the hands are worn the gauntlets. Below the waist and protecting the hips is the skirt of *taces*, and across the buttocks is girt the military belt or *cingulum*. This was often extremely rich in jewels. Covering the tops of the thighs are the *tuelles* or *tuites*. The thighs themselves are encased in *cuisse*s, and the shins in *jambes*. The knee-plates are called the *genouilleres*. The scale-like coverings for the feet are the *sollerets*, and across these at their junction with the *jambes* occur the spur-straps. The sword, of course, is suspended from the left side by the transverse belt, whilst upon the right hip is the *misericorde* or dagger.—HARRY HEMS.

[6769].—**Early-English Woodwork.**—The most complete and finest example of Early English woodwork in England are undoubtedly the magnificent series of oak miserere seats at Exeter Cathedral. There are half a hundred of them, all (save one) dating from Bishop Bruere's time (1234–44). They exhibit a wonderful diversity of treatment—foliage and figures being carved with masterly skill. Portions of the stalls in Salisbury Cathedral are also excellent samples of work of this date, but their misereres are not carved with the vigour those at Exeter evince, and the foliage upon them shows little variety. The stalls themselves are particularly interesting—in that the dog-tooth ornament occurs thereon. I believe this is the only genuine instance of Early English

dog-tooth in wood. In Henry VII.'s chapel at Westminster Abbey there is one Early English miserere bracket. It is crudely carved and very inferior, in artistic power, to the Exeter or Salisbury examples. I may say here that whilst at both the two cities just mentioned the passing visitor is perfectly welcome to inspect and examine the cathedral and its details at leisure, the facilities at Westminster Abbey are not quite so great. Recently I was on my knees before the stalls in Henry VII.'s chapel when suddenly a stern voice at my elbow cried, "The public ain't allowed to touch those there, sir." "All right," I replied, "I merely want to find an Early miserere, which should be here somewhere amongst all these late ones." "I don't know nothing about 'em being early or late, sir," retorted the verger, civilly enough, "but we never lifts up those back rows at all, nor let's anybody else. There's one here. That's an old 'un, but you mustn't touch 'em. Can't possibly be permitted, sir. If you're an architect and wants a private view, you'll have to come, you know, sir, away from public hours and see the clerk of works. My instructions is imperative, sir, to see none on 'em touched. Very sorry, sir! Thank you, sir, exceedingly." Fortunately by the time this harangue was through I had completed my inspection, and the conscientious official and I parted good enough friends. In Edward the Confessor's Chapel, in the same Abbey, the old Coronation chair is a well-known specimen of 13th century woodwork. It dates from 1272, and is, I suppose, by far the earliest specimen of a chair in England. There is, or was until recent years, an Early English roof over the nave of Hales Owen Church, in Shropshire, a sort of wagon roof with tie-beams. At Stanton Harcourt Church, Oxon, there is an oak screen of about A.D. 1260. If I mistake not, the old broached spire of Almondsbury Church, Gloucestershire, still exists. The wood framing of this spire is Early work (1250). Perhaps the very earliest example of ecclesiastical woodwork in this country is at Compton Church, Surrey. In that building a piece of screenwork may be seen which was placed therein during the transition period from Norman to Early English.—HARRY HEMS.

[6776].—**Transferring Oak Carving to Paper.**—"A Northern Student" must put his question more definitely. He may have them photographed on to paper—may draw them on paper—or may wrap them up in paper and take them home under his arm. Or is it papier-mâché counterparts that he requires?—HARRY HEMS.

CHIPS.

Two corner-stones of the new building which is being erected by the Upper and Lower Wortley Liberal Club were laid on Monday. The building, which will be of brick, with stone dressings, has been designed by Mr. James Thornton.

A new girls' school is to be built at Porth for the Lanworno School-board, and alterations are about to be made to Miskin schools, Mountain Ash. The architect in both cases is Mr. Moses Cule, of Pen-trebach.

The local board of Liversedge have adopted plans of Mr. Charles Gott, M.I.C.E., of Bradford, for a main outfall-sewer, about one and a third miles in length, including 450 yards run of tunnelling.

The guardians of the Strand union last week adopted a report by a committee recommending the erection of fresh offices, in lieu of those in Tavistock-street, at an estimated cost not to exceed £10,000. A vacant plot of land in Maiden-lane was suggested at the meeting as a suitable site.

The local board of Ashford, Kent, after much discussion and several visits to other sewerage works, have decided, subject to the sanction of the Local Government Board, to adopt, for the disposal of the town sewage, precipitation, by means of sulphate of alumina and lime, and filtration, by passing the effluent through land.

The Church of St. Mildred, Bread-street, Cheap-side, one of those rebuilt by Sir Christopher Wren, will be reopened on Sunday next, the 27th inst., after internal and external restoration, under the superintendence of Mr. Thomas Milbourne, architect. The stone paving has been repaired by asphalt, in order to render the church dry, and all the monumental stones have been relaid in their places; the open stoves have been replaced by hot-water coils, the whole of the upholstery and furniture of the church has been renewed, and the organ reconstructed with considerable additions.

The foundation-stone of a new schoolroom, attached to the Congregational Chapel, in Carmarthen-road, Swansea, was laid on Tuesday week. The building will be 60ft. by 40ft., and will seat about 400 children, and the contract has been taken for £500, by Mr. Thomas White, of Swansea.

A new wing, added to SS. Mary and Modeven's Roman Catholic schools, Burton-on-Trent, was opened on Monday week. The cost has been £350; and Mr. Hodges, of Burton, was the contractor.

The town council of Burton-on-Trent have under consideration a report from Mr. B. S. Brundell, C.E., of Doncaster, as to the measures which should be taken for the protection of the town from flood. He recommends that the embankment at the south portion of the town be extended from the Bond-end mills to Soho, and points out that all these works are comparatively valueless so long as the council permit fresh buildings to be erected in the floodway of the river.

LEGAL INTELLIGENCE.

LIGHT AND AIR CASE.—(Lawes v. Carter. Before Mr. Justice Fry.)—The plaintiffs in this case, who are freeholders of Nos. 10 and 11, Lincoln's Inn-fields, sought to restrain the defendants, the seedsmen of Holborn, from interfering by their buildings with the light and air enjoyed by the plaintiffs on the ground and first floors of their premises at the back. Whetstone-park, which is only 17ft. wide, interposes between the back of the plaintiffs' premises and some new buildings erected by the defendants, 58ft. in height, in place of some older buildings alleged by some witnesses to have been 28ft., and by others 36ft. or 38ft. high. Mr. Glass, Q.C., Mr. Cookson, Q.C., and Mr. E. Cutler were counsel for the plaintiffs; Mr. John Pearson, Q.C., and Mr. Phipson Beale for the defendants. The Judge dismissed the action with costs, holding that as part of the new building which was opposite the back of No. 10, Lincoln's Inn-fields, had been thrown back behind a courtyard 28ft. wide, it did not cause a greater diminution of light than the old building, and that the interference with the light of No. 11 was so slight that a Jury would find difficulty in assessing the damages.

YOUNG AND CO. v. THE MAYOR AND CORPORATION OF LEAMINGTON.—The hearing of this appeal against the judgment of Mr. Justice Williams and Mr. Justice Mathew was resumed on Monday in the Court of Appeal. The plaintiffs claim a balance due of between £6,000 and £7,000 for completing the waterworks for the Corporation of Leamington, and the latter refuse to pay, on the ground that the contract entered into with the plaintiffs by their engineer, Mr. Jerram, was not under their corporate seal. Mr. Mellor, Q.C., quoted cases decided in the Court of Queen's Bench and the Court of Common Pleas in support of his contention that a municipal corporation were not authorised to provide waterworks for the supply of water to a town, and submitted that in the present case the Corporation acted in their second capacity as the Urban Sanitary Authority under the Public Health Act of 1875, and could not be held responsible for the observance of a contract which had not been sealed in the usual way.—Mr. Justice Brett asked would the learned counsel submit that there was English law to inflict rank and palpable injustice upon anyone?—Mr. Mellor said the judges would hold, no doubt, that in common law no rank and palpable injustice could be permitted. He admitted that there was hardship in the case, but the plaintiffs should have taken the precaution to have their written contract sealed with the common seal. If this protection were not afforded to the ratepayers, public bodies might enter into contracts involving ruinous expenditure.—Mr. Dugdale followed on the same side.—Mr. Harrison, Q.C., replied on the whole case. He submitted that the Corporation were liable; that they were receiving profit and benefit from the money of the plaintiffs, and that they were bound by the law of agency by their engineer, Mr. Jerram, having entered into a written contract with the plaintiffs. The Corporation of Birmingham, for instance, had constructed waterworks of their own, and it was quite within the powers of the Corporation of Leamington to provide a water supply of their own, as they were doing in this case.—Mr. Dugdale denied that the Corporation of Birmingham had built waterworks. They had simply obtained a special enactment to enable them to purchase waterworks.—The Court reserved its judgment.

STAINED GLASS.

WESTMINSTER ABBEY CHAPTER-HOUSE.—Shortly before his death, Dean Stanley proposed a scheme for filling the windows of the Chapter-house of Westminster Abbey with stained glass. For the first of these he sketched a plan of appropriate subjects and met the cost of providing it. The window will shortly be completed and placed in position. A second stained-glass window has been promised by the Queen as a memorial to the late Dean.

Mr. Under-Sheriff Burchell sat last week to assess the damages in an action for breach of promise brought by Miss Hewson, a barmaid at the Gaiety Restaurant, against a young architect named Truefit. The Jury assessed the damages at £150.

Last Friday a new Conservative Club, intended for the use of members of the party resident in Radcliffe and Pilkington, was opened. The building is in the Gothic style, of red brick, having on the ground-floor a large reading-room, to be used for political or other meetings. On the first floor there is a billiard-room, with smaller apartments for committee meetings, &c. The total cost of the building, exclusive of furnishing, has been £1,750, and it has been erected by Mr. J. Allen, contractor, Radcliffe, from the designs of Mr. W. Dawes, architect, Manchester.

Our Office Table.

MESSES. SLATER AND CO., of Oldham, are the makers of a patent adjustable apparatus for doors well worthy of the attention of the profession and the public. The apparatus in question is a draught-preventer or flap, which is fixed to the bottom rails of doors on the outside, and by the pressure of a cushion which fits to the threshold of the doorway, makes an air-tight joint when the door is shut, while when it is opened the flap rises sufficiently to clear the carpet or rug. A model of the "draught-preventer" was exhibited some time ago at the Agricultural Hall, and we may here more particularly describe the apparatus, as we have seen it in use at 70, High Holborn. The invention consists simply of a hinged rail or flap hung along the bottom of door. When the door is opened the apparatus has the appearance of a weather-board projecting at an angle, and sustained in that position by a spring. When the door is closed the rail catches against a plate in the rebate of the frame, and assumes a vertical position, the bottom of it pressing against the carpet and excluding all draught and dust. It is so simple in action that it cannot get out of order, and can be fixed in a few minutes to any door. We can cordially recommend the apparatus of Messrs. Slater to all householders and tenants who have doors which admit draught—a source of constant colds and discomfort in every house. The builder and the architect will welcome this very useful and not unsightly addition to the doors of a house which have invariably to be made to clear thick carpets and mats. We may add that the price for doors up to 36in. is only 6s., and the apparatus can be made in best tanywood or oak from 10s. 6d. The only necessities for ordering the apparatus are the width between the door jambs outside, the position of the hinges of the door, and its thickness. It can also be fixed to folding-doors.

We believe that up to the present the Government have decided not to attempt to deal during the ensuing year with the water supply of the metropolis. The Home Secretary is of opinion that local government must first be established in the metropolis before the water question can be successfully dealt with. Another question which must come on, however—if only in the committee-rooms of the House of Commons—concerns the lighting of London. Three different companies have given notice of their intention to ask Parliament for the right to supply public buildings and private houses in the metropolis with the electric light; and they seek to obtain the usual power of breaking up the streets and interfering with sewers. These will be resisted by the whole strength of the gas companies in London. The Corporation of London and the Metropolitan Board of Works will also take action on the subject, and it is almost certain that they will oppose giving the promoters of the electric light the powers which they ask.

THROUGHOUT Germany the birthday of the Imperial Princess (the Princess Royal of Great Britain and Ireland) has this year been celebrated with special honours. The most striking feature of the celebration was the opening of the new museum of art and industry, in which she has taken an interest for so many years. The new museum is described as a huge square building, erected at a cost to the State of about £150,000. Its architectural style is mainly Classical, and the walls within and without are profusely decorated with sculpture and mosaic. The art treasures already arranged within its walls have been derived from various public and private sources, from the State collections that have hitherto partially served the purpose for which the new and more comprehensive museum is now intended, and from the cabinets of Prussian sovereigns, princes, and other collectors.

DEAN STANLEY has had his will in most things since his death. The successor he named has taken his pulpit. The improvements he desired in the abbey are for the most part to be carried out. The Queen is going to erect one of those windows which the late dean desired to see put in position. But in one matter he is to be defeated. He desired to restore Ashburnham House to the Abbey. But the proposed com-

promise has failed; the house is to be used for Westminster School, and will very probably lose some of its best characteristics. Westminster scholars are hardly the best custodians of an architectural monument.

A SUPPER to the workmen, on the occasion of raising the timber for the roof for his new residence in Portland-square, Carlisle, was given by Mr. Caleb Hodgson, on Tuesday evening last, in the Red Lion Assembly-room. About 60 sat down with Mr. Tom Beatty (of Beatty Brothers, contractors, who had charge of this job) as chairman, supported by Mr. Councillor Corbett; Mr. Graham, clerk of the works, occupying the vice-chair, supported by Messrs. Halliday and Black, contractors for the joinery work. After supper there was a plentiful supply of ale and spirits. The loyal toasts having been given, Mr. Hodgson's health was proposed by the Chairman, and drunk with musical honours, and very cordially responded to by Mr. Corbett, in the absence of Mr. Hodgson. The architects, Messrs. Hetherington and Oliver, were proposed by Mr. John Beatty, who urged the workmen on all occasions to assist the architects in carrying out their designs by good, clean work, so that they might share the pride in an edifice as well as the architects. The contractors were proposed by the vice-chairman, and suitably responded to by the different trades then present.

MR. JOSEPH NETTLEFOLD, managing director and principal proprietor of the great screw-making firm of that name, in Birmingham, died on Tuesday, of apoplexy, at Pitlochrie, Perthshire. Mr. Nettlefold was a Londoner by birth, but had passed the greater part of his life in Birmingham, where he succeeded to his father's interest in the screw-making business of Nettlefold and Chamberlain, in partnership with the present President of the Board of the Trade. On the retirement of the Chamberlain family a few years ago, Mr. Nettlefold assumed the entire management of the concern, which was amalgamated in 1880 with several smaller undertakings of the same character, and converted into a joint-stock company under the name of Nettlefold's (Limited), with a capital of a little over a million sterling. Mr. Nettlefold was a prominent member of the Unitarian connection, and a Liberal, but took little part in public affairs. It is but a few weeks since he announced his intention of presenting his valuable collection of David Cox's pictures to the Birmingham Art Gallery, and this gift had been preceded by other public benefactions, including the site and a material part of the cost of the King's Heath Institute.

THE LORD MAYOR, attended by the Sheriffs of London and Middlesex, will open the Smoke Abatement Exhibition, on Wednesday, Nov. 30, at three o'clock p.m., at the Royal Albert Hall. The opening ceremony will be followed by a private view, and the Exhibition will be opened to the public on and after Thursday, Dec. 1, from ten to four. A great portion of the Exhibition will be shown in action.

LORD DERRY, SIR STAFFORD NORTHOTE, and the other trustees of the Peabody Fund, have been summoned at the Clerkenwell Police Court for allowing certain houses in the vicinity of Brunswick Square, Bloomsbury, to remain a nuisance and unfit for human habitation. The houses had been condemned on sanitary grounds, several fatal cases of fever having occurred in them, and an order was made that the houses should not be used for habitation until further notice. It was explained, however, on behalf of the trustees, that they were not really responsible for the state of things that existed. They had arranged for the destruction of the buildings under the Artisans' Dwellings Act, but the Home Secretary would not grant an order for their demolition until there was a batch of fifteen. That number would soon be reached, when the whole of the buildings would be demolished, and new ones erected in their place.

THE fifty-sixth election of pensioners, in connection with the Builders' Benevolent Institution, was held on Thursday at Willis's Rooms, St. James's, the President, Mr. Ex-Sheriff Burt, J.P., in the chair. There were six candidates, five men and one woman. It was originally intended to elect only two men and one woman; but in consequence of the large amount subscribed in connection with the recent anniversary festival of the Institution, it was determined by the Committee to elect three men.

The candidates were John Willis, aged 65 (second application), who received 2,307 votes; Charles Henry Wood, aged 63 (second application), 1,819 votes; John Loat, aged 84, 1,412 votes; Jonathan Parsons, aged 67, 432 votes; John Cooper, aged 78, 625 votes; and Amelia Stone, aged 60, widow of William Stone (second application), 2,897 votes. Shortly after the close of the poll, at three o'clock, the scrutineers (Messrs. Thos. Stirling and T. F. Rider) reported the result of the voting, as given above, and accordingly the Chairman declared the successful candidates to be John Willis, Charles Henry Wood, John Loat, and Mrs. Stone. Votes of thanks to the Chairman and scrutineers brought the proceedings to a close.

CHIPS.

At the first meeting of the re-elected local board of Oxford, held on Wednesday week, the chairman mentioned that during the year 1,840 yards of new roads had been made up and opened, besides many now in progress; they had also executed 4,670 lineal yards of kerbing and channelling; 1,940 of black bricking and concrete paving; 1,320 of asphalt; and 3,620 yards of sewers and surface drainage. Among the improvements completed during the year were those at New Inn, Hall-street, in St. John's-road, and in Walton-street. Plans for the widening of Magdalen Bridge were in progress, and would soon be laid before the board.

The improvement commissioners of Lowestoft last week instructed their surveyor to prepare plans for main drainage of the southern district, which, including a siphon under the harbour and duplicate drains for sewage and surface water, is estimated to cost £15,000.

In the description last week of the Accrington Conservative Club, the cost was incorrectly stated as £200. This should have been £2,000.

A meeting of the creditors of Daniel Moore, builder, Stafford-street and Bradford-street, Walsall, was held last week. The liabilities were £2,827 6s. 3d., and the assets were estimated at £937 12s. A composition of 5s. in the pound, payable within a week of the registration of the resolution, was offered, and this was afterwards increased to 6s. 8d., the added 1s. 8d. to be secured and paid in three months. The amended offer was carried by a large majority; an amendment in favour of a composition of 7s. 6d. in three equal instalments, at two, four, and six months, receiving only three votes.

Last week a new chapel, which has been erected at Primrose-hill, Huddersfield, for the Baptist denomination, was opened for divine service. The new chapel, which has cost over £1,000, has been erected from designs supplied by Mr. B. Stocks, architect, New-street, Huddersfield, and will accommodate 700 persons. The style is Classic, plainly treated, and most of the stone is from Elland Edge and Crosland Hill.

The largest printing establishment in the North of England has lately been erected at Leeds by Mr. A. Cooke. It is three stories high, and consists of a large open ground-floor, with two stories of galleries running all round, and a large open well. It is mostly lighted from the roof, and the roof glazing is done by Mr. Helliwell, of Brighouse, Yorkshire, on his patent Imperishable Perfection system of glazing without putty.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Arts. Cantor Lecture No. II.
TUESDAY.—St. Paul's Ecclesiological Society. "A Discourse on the Building of the Chief Monastic Orders in England." By J. T. Micklethwaite, F.S.A. 7.30 p.m.
Institution of Civil Engineers. "Forces and Strains of Steel in the Elastic Field (Gun Carriage)." By H. J. Butter, M.I.C.E. 8 p.m.
WEDNESDAY.—Society of Arts. S.p.m.
Edinburgh Architectural Association. "Architectural Notes in Normandy." By Jas. Gordon. 8.30 p.m.
FRIDAY.—Society of Arts. Special meeting for discussion on the Society of Arts Bill. S.p.m.

Throat Irritation.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jubilee. Glycerine, in these agreeable confections, being in proximity to the glands at the moment they are excited by the act of sucking, becomes actively healing. Sold only in boxes, 7½d. and 1s. 1½d., labelled "JOHN EPPS AND CO., HOMOPATHIC CHEMISTS, LONDON." A letter received:—"Gentlemen,—it may perhaps interest you to know that, after an extended trial, I have found your Glycerine Jubilee of considerable benefit (with or without medical treatment) in almost all forms of throat disease. They soften and clear the voice.—Yours faithfully, GEORGE HARRIS, L.R.C.P.E., Senior Physician to the Municipal Throat and Ear Infirmary."

Lamplough's Pyretic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, RHEUMATISM, SMALLPOX, SCARLET-FEVER, and many other ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. Use no substitute. See Medical Testimony.

Holloway's Ointment and Pills.—Skin diseases scrofula, scurvy. This class of complaints not only affects the individual, but is too frequently transmitted to the offspring. How important, then, under such serious consequences, it becomes, thoroughly to eradicate strumous taints from the blood. Holloway's Ointment and Pills uproot all such latent corruptions.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to **CHARLES TRASK,** Norton-sub-Hamdon, Ilminster, Somerset. —[Advrt.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates. General Repairs and Alterations Executed: Experienced Workmen always in readiness, and sent to any part of the country. —[Advrt.]

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE.
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.
(See trade advt. on p. XXIII.) Advrt.

TENDERS.

* Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ABERDEEN.—For additions to Woodbank House, Cults, near Aberdeen. Messrs. Ellis and Wilson, architects. Quantities supplied by the architects:—

Accepted tenders:—	
Masons' work:—	
Thorn, G., Aberdeen ...	£710 0 0
Grant, W., Aberdeen ...	550 0 0
Davidson, G., Aberdeen ...	51 10 0
Matthews, J., Aberdeen ...	100 0 0
Stephen and Campbell, Aberdeen ...	160 10 0
Donald, G., ...	81 10 0
	£1,653 10 0

ABERDEEN.—For the erection of public school in King-street, for the School Board, to accommodate 840 pupils in three departments—seniors, juniors, and infants, with caretaker's house attached. Messrs. Ellis and Wilson, architects. Quantities supplied by the architects:—

Accepted tenders:—	
Masons' work:—	
Mitchell and Co., A. ...	£2,750 0 0
Johnston and Fullerton ...	1,764 0 0
Wilson, J. ...	186 4 0
Willis and Conden ...	343 0 0
Masson and Findlay ...	335 5 0
Garvie and Sons, J. ...	160 0 0
	£5,538 9 0

AMERSHAM.—For building a shed for tramps to work in, for the Amersham Board of Guardians:—

Keen, Amersham (accepted) ... £62 10 0

ANGLESEY.—For new mansion, for Capt. G. Pritchard Rayner, at Trecawen, Anglesey. Mr. R. G. Thomas, Menai Bridge, architect:—

Bromwich, Foster and Co., Rugby (accepted) £13,790 0 0

(All casting and stone provided by proprietor.)

ANGLESEY.—New stables for Captain G. Pritchard Rayner, at Trecawen, Anglesey. Mr. R. G. Thomas, architect, Menai Bridge:—

Mr. D. Owen, Llangefni (accepted) £1,500 0 0

(All casting and stone provided by proprietor.)

BAGSHOT.—For new stables, Pennyhill Park, Bagshot. Mr. H. Pettit, architect:—

Norris ...	£3,287 0 0
Boyer ...	3,273 0 0
Holland and Hannen ...	3,267 0 0
Nightingale ...	3,195 0 0
Lawrence ...	3,150 0 0
Knight and Sons ...	3,080 0 0
Stimpson and Co. ...	3,045 0 0
Watson ...	2,930 0 0

BATTERSEA, S.W.—For new roads and sewers, for Mr. F. Snelling, on the estate of the late Mr. T. Taylor, at Lavender Sweep, Battersea Rise. Mr. C. J. Bentley, surveyor:—

Williams, W. R. ...	£1,060 0 0
Ball, J. ...	1,030 0 0
Harris ...	900 0 0
Nowell and Robson ...	820 0 0
Neal, R. and G. ...	790 0 0
Blackmore ...	790 0 0
Neal, J. ...	780 0 0

BERMONDSEY.—For two new houses adjoining No. 140A, Abbey-street, for Mr. W. Wilkins. Mr. E. Crosse, 6, Bermondsey-square, S.E., architect. Reduced estimate:—

Winer, W. (accepted) ... £650 0 0

BERMONDSEY.—For furniture and fittings, Bermondsey Town Hall. Messrs. John Elkington and Son, architects:—

Seix and Son ...	£1,220 0 0
Lucraft & Son ...	1,150 0 0
Schoolbred & Co. ...	1,102 12 0
Mr. F. C. Turpin ...	945 0 0
Tarn and Co. ...	910 0 0
Bartholomew and Co. ...	895 0 0
Atkinson and Co. ...	873 0 0
Finch, J. and Co. (accepted) ...	801 12 6

BETHNAL GREEN, E.—For alterations at No. 61, Green-street, Bethnal Green, for Mr. Mardoy. Mr. C. A. Legg, architect:—

Wood, F. and F. J. ...	£432 0 0
Judd ...	341 0 0
Elves ...	340 0 0
Lusk ...	332 0 0
Farrish (accepted) ...	320 0 0

BLACKBURN.—For supply of 500 ash-tubs and 500 excreta-tubs to the Corporation. Mr. W. B. Bryan, borough engineer:—

Accepted tenders.

Franklin, J., Blackburn, and Purvis, W., Padiham.

BLACKBURN.—For supply of a cast-iron Coff-y's still and heating boiler, to be erected at the Fensington Ammonia Works, for the Corporation:—

Heald, J., Chorley (accepted).

BRIGHTON.—For temporary buildings and annexes to the Pavilion, for the Health Congress:—

Humphreys, J. Charlton, Brighton (accepted).

BROMPTON.—For the Oratory New Church. Mr. H. A. K. Gribbles, architect. Mr. H. Smith, and Messrs. Lee and Soa, surveyors:—

For the first section of the cupola:—

Shaw, G., Westminster (accepted) £4,500 0 0

For St. Wilfrid's Chapel (exclusive of the breccia columns):—

Shaw, G. (accepted) ... 3,000 0 0

For the Magdalen Altar (exclusive of floor and marble rails):—

Riggall	1,980 0 0			
Holmes (accepted)	1,847 0 0			
SOUTH TOTTENHAM.—For mission chapel at South Tottenham. Mr. C. Bell, F.R.I.B.A., architect:—				
Humphreys and Son	£1,257 0 0			
Thornton	1,162 0 0			
SOUTHBURY, LANC.—For supply of 60 cast iron gully grids, to weigh 2 cwt. each. Mr. W. Crabtree, borough surveyor:—				
Horrocks and Owen, Tyldesley, Manchester (accepted), 3s. 11d. per cwt.; Howard and Ball, Ormskirk, 4s.; Smith, Patterson, and Co., Blaydon-on-Tyne, 4s. 6d.; J. and S. Roberts, West Bromwich, 5s. 4d.; Jukes, Coulson, Stokes and Co., 13, Clement's-lane London, 5s. 4d.; The Brymbo Co., Wrexham, 5s. 6d.; Joseph Clayton, Preston, 5s. 6d.; J. Hollinrake, Rochdale, 5s. 6d.; S. Rowland, Wigan, 5s. 6d.; J. Brown, Bolton, 5s. 7½d.; M. and Co., Leicester, 5s. 8d.; J. Fletcher and Sons, Salford, 5s. 9d.; Wear Valley Foundry Company, Darlington, 5s. 10d.; W. Miller and Sons, Wolverhampton, 5s. 11½d.; J. S. Smethurst, Warrington, 5s. 11½d.; Clay Cross Company, Clay Cross, near Chesterfield, 6s.; Goddard and Messy, Nottingham, 6s. 3d.; Hill and Smith, 6d.; Hargill Hill, 6s. 3½d.; C. H. Taylor, Leeds, 6s. 6d.; Haigh Foundry Company, Wigan, 6s. 8d.; W. C. Holmes and Co., Huddersfield, 6s. 8½d.; Walker, Pendleton, and Co., Liverpool 1, 6s. 9d.; Wm. Jones and Sons, Warrington, 6s. 11d.; Sharpe and Co., Lancaster, 7s.; J. and A. Law, Glasgow, 7s. 2d.; Abbot's Foundry Company, Falkirk, 7s. 6d.; Langley Mill Engineering Company, Langley Mill, Notts, 7s. 7½d.; Ludlow and Sons, Glasgow, 8s. 8d.; S. M. Mitton, Birmingham, 8s. 1d.; R. and J. Rankin and Co., Liverpool, 9s.				

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 2, 1881.

INTERNATIONAL EXHIBITION OF SMOKE-PREVENTING APPLIANCES.

AFTER some delay and disappointment to many of the exhibitors, the Smoke Abatement Committee of the National Health and Kyrle Societies have opened their exhibition of smoke-preventing appliances in the arcades and quadrants inclosing the gardens of the Royal Horticultural Society. The arrangements made by the committee were of the most complete kind, and the exhibition, as may have been anticipated, includes apparatus of all kinds from improved firegrates and cooking appliances to varieties of bituminous and anthracite coal and special kinds of fuel. But the principal value of the exhibition lies in the fact that it is intended to be a competitive trial of the merits of the several appliances known for preventing or lessening smoke and economising fuel, and with this object the promoters have not confined it to the production of British manufacturers, but have invited the exhibition of appliances of manufacturers and inventors from all nations. The exhibition comprises two classes of appliances, one having reference to domestic purposes, and the other to industrial uses. Glancing at the different inventions for the purpose of preventing or abating the smoke, we notice a variety of plans for effecting the purpose, though the majority of these can claim no originality. Many of them have been introduced by different inventors during the last hundred years in one form or another, and others are modifications of plans well known to the architect and engineer. There are several means, for instance, seen for regulating the quantity of fuel consumed: some of these depend on movable bottoms for raising the fire, and of introducing fresh fuel below; others are constructed on the Arnott principle, of preventing smoke by igniting the fuel on the top, and allowing the coal to burn downwards, for which purpose a movable blind is made to move down as the fire burns; such is the principle admirably shown in Messrs. Edwards and Sons' modification; while another ingenious appliance shows a movable back, by which the fuel is pushed forward as it is burned, and the fresh coal is introduced behind. There is also an invention for covering the fire by a flap, and for diverting the smoke into side flues, and for introducing fuel at the bottom of the grate.

Commencing at the east arcade adjoining the Exhibition-road, we notice several exhibits. Kite and Company still retain the excellence of their ventilating or exhaust contrivances, specimens of ventilators for extracting sewer-gas from soil pipes, inlets for letting down fresh air into drains, ships, &c., and a capital exhaust ventilator for farm buildings, warehouses, &c., which can be fixed upon the ridge—may be seen in action. We have already spoken of the siphon system of ventilation for drains, recommended by Messrs. Kite; and we may now refer particularly to a capital chimney-top to prevent smoke, and a hay-drier, constructed on the same principles. Passing by a stove for cooking, with a jack for turning the meat, shown by W. Sugg and Co., we reach some interesting sanitary exhibits by the Wilson Engineering Co., particularly the "smoke-consuming range and stove," by which the cold air is made to travel through flanged chambers, so that the heated air mingles with the smoke, &c., producing perfect combustion. We next come to

several appliances of a very useful kind. George Haller and Co., of Lime-street, E.C., are the manufacturers of a patent "hot-air gas-stove" (Kohlhofer's). By this principle the products of combustion are immediately divided and carried through flues or pipes which join and unite into a common flue. A model of a chimney breast is shown with the flue-pipes descending on each side, and then rising where they join a centre flue. Cold air is warmed and discharged by openings above. The advantage of this system is that it can be made to retain the open firegrate, and little or no smoke is evolved. A capital radiating stove for apartments is shown by Michel Perret, Paris, called the "Calorifere." The water-cased firegrate for boilers is also an economical plan. The "Griffin" firegrate, which burns coal or coke, is an attempt to produce a perfect combustion of both fuel and smoke. The smoke is prevented by a super-heated air-chamber behind and above the fire, which heats the gases or smoke to the temperature necessary for its conversion into flame. Another economic open fireplace, the "Shrewsbury," invented by Wm. White, F.S.A., architect, and made by T. Gregory, of Clapham Junction, is self-feeding, smoke-consuming, and wasteless, according to its author. The "Warming Apparatus," under the same name, is a furnace of fireclay placed in an air-chamber, with gills, self-feeding, and of slow combustion. The feed is at the top and is a fireclay funnel over centre of the fire. As fire burns the fuel descends, and no cold air can come in contact with the fresh-kindled fuel. The smoke is therefore made to pass through hottest part of fire, and the combustion is thus more perfect. No iron is in contact with the fire, and the smoke-draught carried on either side, and then at the back is brought down by two flues uniting in one central flue at the bottom, from whence it is carried off by the chimney. The gilled iron outer case is fitted together by sand-groove joints. It is said the apparatus will burn for 15 hours without attention. Thomas Potter and Sons, of Oxford-street, W.C., exhibit Mr. H. Saxon Snell's patent smoke-consuming revolving firegrate, by which means the fire or fuel can be reversed, so that the new fuel, when placed on the top, can be inverted and the fire made to burn downwards, and the products of combustion consumed.

One of the best appliances for preventing smoke is introduced by A. E. Engert, by which means the ordinary open grates can be fitted with a coking-box at the back, which is filled with the fresh fuel, made movable, and can be pushed forward into the fire by a movable plate moved by a screw, which is turned by the poker in front. As the coals are brought forward and consumed, the plate can be turned back and the box refilled. The object of this simple and scientific arrangement is to prevent the cold air from coming in contact with the gases rising from fresh coals. The gases are condensed, and hence smoke prevented or reduced. The apparatus has the advantage of simplicity and economy, and while the fuel is thoroughly burnt smoke is abated. Mr. Engert's vertical boiler has the coking boxes on each side, and movable plates, actuated by racks, push the coals into the furnace. The principle is the same as in the other of this inventor's apparatus, namely, to admit only ready-heated air, so that as the gases are liberated they are burnt. The "Smoke-burning Gill Register" of the Derwent Foundry Co., to burn common coal, is constructed with flues at back with an air opening below, and a grating above fire to admit warm air into room, and appears to give a cheerful fire. One of the completest exhibitions of grates and chimney-pieces is the collection of Barnard, Bishop and Barnards, of Norwich and Queen Victoria-

street, in block XVIII. The exhibits occupy 4 or 5 bays of the east quadrant, and are furnished in a highly decorative manner. The "Glow" slow-combustion firegrate consumes the products of combustion, and from its construction, which consists of an air-chamber behind the fire, a fire-brick back, and a patent fire-brick baffle over the fire, into which hot air is discharged from the air-chamber, there is a large surface of heat presented to the room, and smoke is obviated. The "slow-combustion stoves" are too well known by our readers to need description; there are several modifications exhibited, besides a large dog-grate in an oak and tile chimney-piece, and we believe the smoke nuisance would be amply abated if these grates were generally used. The "Wonderful" automatic smokeless grate, made by Archibald Smith and Stevens, we have already described in these pages. Three or four modifications of this grate may be seen in operation; it burns any kind of coal or coke. The principle of its construction is that the gases are distilled in the fuel hopper, and are converted into flame instead of smoke; the feeding is automatic. The fire can be regulated by a damper, the gases being compelled to pass through the fire, and the combustion be made quick or slow. The grates burn 24 hours without feeding, and their appearance, the firegrate projecting into the room, is in their favour. Messrs. Rosser and Russell shows a large hot-closet and steaming apparatus in the lobby at the end of quadrant. The fire is regulated by raising or lowering the bottom of the grate by a rack- and-pinion movement, instead of by the usual side-plate action. The reversible firegrate, the "Leopold," is a rather pleasing form of this mode of inverting the fuel. We also notice a circular gill stove fed at the top, and ornamented with brass fittings of attractive appearance.

In the east quadrant Fredk. Edwards and Soa, of Marlborough-street, show several of their very excellent smoke-preventing slow-combustion grates. Messrs. Edwards' is a modification of the Arnott grate: there is fire-basket for coals, which is lighted on the top; as these burn downwards, a shutter or blind is moved down in front of the fuel, balanced by weights on each side. The Arnott sunken ash-pit is dispensed with, and a wire basket in front of grate catches the coal that may fall out, and a trough below receives the cinder. At the top of fire is a register which is adjusted easily at the top. The grate has a neat and artistic appearance, and has been introduced in several buildings with the best results. The kitchen on Count Rumford's system of coking by more than one fire, is well worth inspection, and economises the heat. Anthracite or gas can be used. We hardly need here to dwell on the advantages of Messrs. Edwards' modifications, which are well-known to our readers and all who have studied the subject of smoke prevention. Clark, Bunnett, and Company, are the exhibitors of Ingram's patent "Kaio-Kapnos" stoves which burn coke or coal. The grate is well adapted for preventing smoke, and is made both hygienic and non-hygienic, the former allowing warm air to enter room. A flue passes round the back of fire and below it, so that the air is thoroughly heated, and the gases evolved from the fire consumed. It has the advantage of an open fire easily regulated, and can be used for heating rooms by warm air. The kitchen range is constructed on the same principle.

The special appliances exhibited by T. J. Constantine, of Fleet-street, are worthy of notice for the manner in which the fire-door of the range known as the "Treasure Cooking Range," is made to insure the air being thoroughly heated before it reaches the fire. This is effected by a triple-chambered fire-door, and the consequent prevention of

smoke and saving of fuel. There are gilled flanges at the bottom of oven, and by the fire-basket being inclosed in a number of air-tubes, the heat is fully utilised, and the top of fire is covered with a cloud of hot air. A movable ash-pan, one part of which receives the dust, is an arrangement which allows of the former being re-used. The construction of this range appears to be a perfect adaptation of scientific principles, insuring complete combustion of the fuel, and a freedom from "clinkering." The hot-air radiating slow-combustion stove is also worth attention.

Doulton and Co., of Lambeth, make a large and important display of their well-known radiating tile stoves and open fireplaces. One of these is a portable stove, with ventilating tile shaft for introducing warm, fresh air. An open fireplace, with painted tile sides, having siphon flues for the utilisation of smoke as a means of heating, is particularly worthy of remark; and the decorative completeness of these open firegrates is not the least recommendation in their favour. Another exhibit shows a large tile stove, of a pedestal or pier-like form, 8ft. or 10ft. high, in which an open fire as well as a close one are combined. The Doulton or majolica tiles, in green and brown, of richly-moulded and embossed patterns, with which this "combination" stove is encased, make it a very ornamental object. It is entirely of fire's-ay lining. The slow-combustion slab-stove, and the Doulton ware ventilating-shafts are admirable improvements, and will find their way into public favour.

Yates, Haywood, and Co., of Upper Thames-street, are the exhibitors of a variety of improved stoves, and a patent "smoke curer,"—a grate with a top which falls over fire and prevents smoke. The appliance is simple, and is worth notice as a means of obviating smoke in an inexpensive manner. Any coal may be burnt. In the west quadrant the same firm are exhibitors, M. Feetham and Company have a large display of grates and economic kitchen ranges, constructed to consume smoke. In the Hurst grate the hot smoke passes through the fire by an opening at the back. There is a shutter in front, and a warm-air chamber. The draught is through the fire, and no ash is made. One dust-consuming kitchen range will burn dust or small coal. Another range has the openings at top for ventilation, and the heated air is brought to the top of fire, the latter being raised as burnt. E. R. Hollands is the exhibitor of a grate for smoke prevention. The bottom is of open bars, but circular in section; a handle at the side brings a rake-like instrument into play, which rake can be raised through the bottom bars, lifting the burning fuel. A space is thus left for the reception of fresh fuel below, and smoke is not made. The invention is certainly a very ingenious means of allowing fresh coal to be introduced below the fire. The Coulbrooke & Co. have one of the most remarkable displays. Two handsomely fitted and decorated recesses in the Adams style are the chief features, and represent portions of rooms or fire recesses. One of these recesses is fitted with three fireplaces and grates, the mantel and over-mantel being of the style of the 18th century, painted of a celadon colour in one case, and having an "iron bridge controlled combustion" stove. These grates are intended to burn anthracite or ordinary coal, and are of pleasing design. In the projection between the two recesses is a very unique mantelpiece, in the Adams' style, with a Chippendale oak mantel above, having curved side cabinets for bric-a-brac, and a Venetian mirror in the centre. The grate is a projecting hob-grate, in the style of Chippendale, with brass panels and tile covers, and the whole has a very rich effect. The mantelpiece is painted celadon and

white. A bedroom "mantel-sham," designed by Mr. R. Norman Shaw, R.A., is another example. The "Kyrle Grate" is an invention for burning anthracite coal, gas-coke, and other fuel, and is said to give perfect combustion, and is easily controlled. The "iron-bridge grate" of this company can be adapted to any opening, and may be either straight, recessed, or projecting. Holland's smoke-preventing grate, and John M. Stanley's kitcheners and stoves, by which the gases generated are induced through the fire, are worth notice, and several specimens are noteworthy and are to be seen in operation. In the patent furnace of the latter the air passes through the burning fuel. A very conspicuous position in the west quadrant is occupied by Musgrave and Company, Belfast and New Bond-street. Their patent slow-combustion stoves and air-warmers for coke or anthracite are well known. The smoke and gases are consumed, and a chamber inside is provided for ventilating purposes. The "Ulster" smokeless stove-grate is like an ordinary grate; there is a false back and feed for fuel, which latter drops out in front as required, and the smoke is arrested and burnt. There is also a folding curtain in front, perforated, which acts as a blower, the fire being seen through the perforations. The hand-painted tile stoves are exhibited in a variety of designs, and the smoke passing down and then up, a large heating surface is insured.

Near the entrance in the eastern arcade we notice several interesting specimens of open fire-grates, stoves, kitchen-ranges, &c. The visitor will first find a two-horse power, silent gas-engine, intended to work with ordinary coal-gas, exhibited by Crossley Brothers, of the Poultry, the economy and advantages of which are already favourably known. In block XXV., Billing and Company, new Oxford-street, show stoves, for gas, cooking-stoves with double-jacketed oven, and a variety of ornamental brass-work. The "Sundial" gas-stoves appear very economical heaters. G. Wright and Company, Burton-weir, Rotherham, exhibit a patent "bivalve" open grate, fitted with Dr. Siemens' gas and coke apparatus, an economic cooker. J. C. Stark and Company, Torquay, are the manufacturers of gas-cooking, heating and ventilating stoves, which are worth notice for the manner the gas is under control, thus preventing smoke also, and for the current of air introduced under the oven. In the same class of exhibits, Strole and Company show some reflecting gas-stoves in which the copper reflectors can be removed for cleaning.

Steel and Garland are the exhibitors of a variety of patented grates and stoves, as the "Wharfedale." Redmayne's patent, the "pillar-stove" burns any kind of fuel; the combustion is slow, and the hot gases are compelled to pass through the fire, so that smoke is prevented. The circulation of the heated products downwards and through the base, and then up the circular pillars at the sides, insure a large heating power, and the "pillar-stove" makes an ornamental feature in a hall. Wilcock and Co., Leeds, are exhibitors, and so is the Patent Steam Boiler Co. E. H. Shorland, of Manchester, has also on view a variety of admirable grates and appliances, to which and to other exhibits, too numerous even to mention here, we shall return in our next notice.

WINTER EXHIBITIONS.

THE Winter Exhibition of the Society of British Artists in Suffolk-street, Pall-mall, is strong in works by well-known artists and members. In the large room we meet with pictures by A. Ludovici, H. R. Cluty, J. T. Peele, J. C. Waite, A. F. Grace, W. H. Bartlett, Carl Bauerle, Gustave Bréanski Hayllar, Wyke Bayliss, T. F.

Goodall, A. J. Woolmer, P. Macnab, W. Dendy Sadler, J. S. Noble, Geo. Cole, J. Gow, Edwin Ellis, A. Wardle, T. Hine, Edith Hayllar, E. A. Waterlow, H. Caffieri, amongst others. On the end wall the large picture by A. Ludovici will be noticed as a boldly painted imaginative subject. "Le Feufollet" is a skilfully handled fancy; the nymph-like figure, which is seen hovering over the dark swamp, if it does not entirely satisfy our ideas of proportions, is made to suggest the subtle luminous appearance of the will-o'-the-wisp. Just below it is a long canvas, by Horace H. Canty, a member of the Society, who has done excellent work. The "Play Hour" is a broad and feeling picture, in which a number of light-hearted girls are seen disporting themselves on the verge of an open field. "Spring," by Flora M. Reid, is prettily conceived; and H. E. Grace's "Still Life" (11), and E. G. H. Lucas's "Reminiscences of Schoolboy Life," No. 12, must find admirers, for their unassuming records and careful minute execution. A large picture by Lane Calkin represents the parting of a sailor and his wife. The figures and interior of the cottage are depicted with much power—rather hard in colour if anything, yet the incident is touchingly told. Kate Amphlett's "Early Morning" (37), is a solidly-handled landscape. The morning breaks in the sky, and the water-filled ruts tell of a rainy night, and are rendered with much feeling. Mrs. A. Lukis Guerin, in her decorative arrangement of tiles and twigs of appleblossom (40), has displayed a rich treatment in a blue key of colour, and the natural rendering of flowers receives ample recognition by the talent of T. G. H. Miles, in his "Chrysanthemums" (49), and in Mrs. Rose Marshall's "Spring Blossoms" (47). Few painters of incident have done better work than W. H. Bartlett, an old member of this Society. His picture, representing a studio, or "School of Painting under the Direction of MM. Bougereau and T. R. Fleury," is skilful in the accessories of light and shadow. The painter has taken the scene during a rest of the nude model, who is enjoying his pipe near the fire in the brief repose. The students are busily engaged chatting and smoking, and the group is a active one.

Of the few landscapes, we note as one of the best, J. E. Grace's "Sweet Autumn Time" (56), a work in every sense worthy of the artist's ability. There is a natural sweetness of colouring and grouping about this picture which charms. The aerial perspective of the distance, the lake, and the screen of twining beech in the foreground, are admirably painted. H. Garland's "Ferry Boat" is also clever. Near this we pass J. D. Watson's "Hasty Toilet," which is well worthy of the painter of "Corporal Trim," and W. Mouat London's "Study of Head" (62) is boldly drawn and coloured. Three small cabinet pictures call for notice. "Kurd Peasants" is a marvel of transparent colour and delicate handling; "Sport," by G. Jarvis, and "Dorothy," by F. H. Potter. The "Interior of Amiens Cathedral" (91), by Wyke Bayliss, is a finely coloured perspective, though the detail is coarse, and the work cannot compare with former exhibits by this master of luminous architectural interiors, nor with the water-colour drawing by the same hand in another room. An amusing incident of the old-fashioned village Squers is told by J. Barr (92), in his usual faithful style. "Coming from the Corn," by P. Macnab, is also a good specimen of this artist's power in pastoral landscape. There is a pleasant soft chiaroscuro in T. F. Goodall's "Winter's Morning on the Yare"; and "Reedham Ferry" (117), is another choice bit of colour and reflected light, with much sympathetic appreciation for effect. W. Dendy Sadler, a well-known painter of quiet satire directed chiefly

to the more prosperous side of monastic life, has, this year, a well-executed picture of a portly old abbot, in good humour, engaged in scanning a grant (120). The parchments on the floor, and the cabinet filled with similar documents, are cleverly painted, and the whole interior has an air of comfort recalling the richly-endowed convent. "Rehearsing" (138), by E. Pavy, is well finished and delicately coloured; and above, the eye is attracted by a picture by H. Helmick's "Presents for his Reverence" (144), a highly finished interior representing a poor woman with her shoeless daughter offering a gift to a venerable ecclesiastic seated in his study. A depth of tone and shadow and colour are characteristic of this work. J. White, in 179, has produced a large picture, in which with characteristic feeling and power he has portrayed an incident of humble rural life, and near this we find a large landscape "On the Heath, Hampstead," by F. Hines, painted with power and fidelity to nature. W. Holyoake's "Coming Rivals" (187) occupies a central position in the room, and is a large picture, showing a group of country lasses loitering at the side of a roadway, where they have apparently been receiving the attentions of a young gallant. A troop of soldiers with red coats are making their appearance down the road, and have attracted the notice of the damsels. The roadway and foreground are wanting in perspective and detail, and the manner the feet of one of the girls is drawn is rather unnatural. Edwin Ellis, well-known as one of the foremost masters of the French landscape school, exhibits several characteristic pictures. Nos. 145, 196, 244, 294, 440 are intensely vivid renderings of nature. "In Squally Weather" shows a deep green sea, a dashing work, executed with all the verve and technical power of the artist. "An Old-World Corner" (440), "Mending Nets" (477), are both remarkable for vivid colour, luminous seas, and sharp-reflected lights. We must speak in praise of the admirably bright, spring-like studies by H. Caffieri, "Getting Firewood" (193), "Birchwood" (352), "Sunshine" (362), all pictures of birchwood glades, brightened by gleams of sunshine and children. Ernest A. Waterlow's "Timber Clearing" (195), W. H. Gadsby's "Windfall" (201), J. R. Reid's "Old and Young," Claude Hayes' "In the Orchard," and Carl Bauerle's "Returning from the Field," are all delightful studies.

In the south-east room we notice J. M. Burfield's "De Trop," a gorgeously furnished interior; H. H. Canty's "Home of the Wildfowl," solid in handling; J. Haylar's "Chatty Letter"; a pretty study by P. Macnab (259); S. C. Henley's "Special Pleading," among a crowd of other works. Clear and grey-toned, full of misty light, is J. White's view of "The Dart"; J. E. Grace's "In the Gloaming," and F. W. Hayes' "Llyn Du, Carnarvonshire" (389), are both charming pictures. A. Ludovici's "Reminiscence of Drawing-room Manners" is a rich study in the artist's polished style of the costumes and decorations of the 18th century. J. White sends a sympathetically-painted picture in "Crums," in which the treatment of light and shade is exceedingly well managed. "Homewards," by E. A. Waterlow (431), "Winter," by L. C. Henley, are both clever; also, the former has the high lights put in over the darker objects—a method very tellingly practised by the "impressionists"; and we also admire Nos. 438, 440, 445, A. Glendenning's broadly-handled sketch on "The Thames" (447), Edith Haylar's cabinet-picture (458), and No. 445. Recording our impressions in the north-west room, C. W. West's "A Student of Anthropology," a lady in a study, is cleverly painted. Edwin Ellis has a fresh, breezy

piece in 477; and J. Morgan in "Their Last Resource," two urchins trying to extract the contents of a money-box, has drawn an incident with a moral. There is much freshness and soft-handling in Jas. Haylar's "Archery Grounds" (486), and J. White's study, "The Well"—a girl seated near a natural spring on the verge of a common—the last is graceful in composition and pleasing in colour. A low key of colour, grey in tone, pervades H. T. Schafer's masterly picture "The Old Captain," thoroughly French in manner, and our notes would hardly be complete were we to leave unmentioned the "Silver Birch" in the autumnal scene, by H. C. Fox (537), handled with much skill and in an impasto style; the reflected light and luminous atmosphere in E. Ellis's No. 547; Stuart Lloyd's freely painted "Cottage Garden" (548) with its peep of blue sea; No. 549, the study of Friscilla, by W. H. Weatherhead; and the vivid fresh picture in the corner of room by G. F. Munn, "Low Tide" (527).

The water-colours comprise a few works by well-known hands. Of the architectural drawings, we must speak highly of Wyke Bayliss's fine "Interior of Trèves Cathedral" (634), in which all the mass and shadow of Romanesque piers and walls, illumined by a glow of light from painted glass, is contrasted with rich carving of the screen and walled choir of a later style. For light and shadow this drawing sustains the ability of the artist. J. J. Hodson, in "Rue Molé, Troyes" (571), gives a pleasantly grouped bit of old houses; after which must be mentioned R. Phené Spiers's "Mont St. Michel, Normandy," a masterly drawing of the old impregnable rock-built fortress.

B. W. Spiers has another of those marvellous specimens of his transcriptive power for minute finish in "Curiosities of Literature" (574), a heap of old books, odds and ends; we remark, also, W. Paget's study of "Oats" (580), W. Langley's broadly-handled sketch of a "Cornish Fishing Village" (588), J. B. Coughtrie's "Gleaners," Bernard Evans' "Valley of the Dee" (612), despite a want of atmosphere; A. Powell's charming sketch of Cookham (616); also a careful drawing, by Harry P. Gill, of Battersea Bridge; Edwin C. Gardner's sketch of Poreh, St. Mary's, Oxford; S. J. Hodson's "Fruit Market, Nuremberg"; view of Dean Stanley's Resting-place in Westminster Abbey (691). Among classically-conceived subjects, E. T. Hayne's "Love's Oracle" is worth notice for its quiet refined drawing and colour, and in scenery, L. Watts' "Broadstairs," and J. Finnie's "Mill Scene, North Wales," (751), will find appreciative admirers.

The Dudley Gallery, opened last Saturday, is full of choice cabinet pictures. Rosa Koberwein's study of "Childhood" (3), is sweet and delicately painted, but the face of the girl is pale, and hardly embodies the lines of the poet, the "healthy cheek, red ripening lips." Several pictures near claim mention. "A Welsh River, Dolgelly" by C. J. Lewis; "A Tiff," by Alfred Taylor; "Peel Castle," with the fresh waves breaking on the shore, by G. de Bréanski; "Evening in the Fields," by A. Verey; "Narcissus," by Fanny Stable, are all skillfully-painted subjects. Mr. Howard Helmick's "The Weather Prophet," an old man, with pipe in hand, looking out of his cottage-door, is solidly painted, and exhibits careful execution. Ernest Waterlow's "Burning Weeds" is a bold rendering in the naturalistic vein. Hilda Montalba rivals her sister in the little gem "Waiting for Beppo," which is as thoroughly poetical in its conception as it is highly finished. Near it we remark "Steining Market," by Jules Lessore, a clever bit of village life. The cattle and red brick houses are very truthfully painted. A study of fresh moorland, with a pathway, is shown by Joseph Knight,

in his exquisitely-finished manner. The tufts of fine grass are faithfully rendered. "Grey Day," by G. F. Munn, is a freshly-painted study; and the same artist has a broadly-treated picture, "The Walls of La Hougue" (69), a powerful study in a low key of colour. T. F. Goodall's "At the Boatyard" is a clever piece of deep shading, effective in composition. We remark also, "Street in Verona," by John O'Connor; "A Lock-Keeper's Garden, Thames and Severn Canal," a brightly painted picture by Alfred Parsons. "A Cornfield," by Joseph Knight, is a careful study of foliage and sheaves, and a "Venetian Water Carrier," by W. F. Yeames, R.A., will be admired for the pleasing face. W. Dendy Sadler, whose graphic pencil has recorded many incidents from monastic life, has in "A Feast Day" (101), shown a monk descending a staircase with a sirloin of beef; the drawing and accessories are well finished. John Collin shows a humorous picture, "The Reluctant Model," an artist endeavouring to adjust a life-size lay-figure. J. Aumonier is, as usual, very felicitous in his river scenery, "The Thames at Pangbourne," a brightly painted piece; "Winter" (150), by Claude Hayes. W. Bannerman's "Il Penseroso," and "Manor House, Great Chalfield," by Cyrus Johnson, are clever. At the end of the gallery P. R. Morris, A.R.A., has an ideal study, "Voice of the Deep," two girls, one with a bundle of wood trudging along the sea-shore against a strong wind, which has broken the sea into great waves. "Going Home," by John White, is a very a boldly-painted incident in a French manner; the sea and illumined evening sky are effectively rendered. David Carr, in "Hauled Up," "The Village Inn," by Arthur G. Bell, and "Rochester," by C. W. Wyllie, are skilful works. Inlandscapes we must name Arthur Severn's "Early Morning, Amiens," a street in the old city, with its mid-stream; and Alice Havers, "Footsteps," a couple of gaily-dressed young ladies in a field attentively listening. G. Koberwein Terrell in "Long Time Ago," represents the pensive face of a young woman, evidently pondering over the past. J. W. Nicol has a clever study of "A Boy-cotter," a little bully laying wait. "Clarrissa" is a pleasing face, by R. J. Gordon. Poetical themes are few. "Wind," by E. Matthew Hall, representing three female figures, with flowing drapery, is a clever embodiment. "The Gipsies engaged Winnowing" (260), by Fred Morgan, are drawn and coloured with much freedom; and Ada Tucker, in her curious little genre picture, "A Harmony in Black and Gold," a black kitten against some bronze plate, has displayed some taste. "A Peep of Sunshine" (278), by J. W. Buxton Knight, is a clever study of atmosphere in its sullen mood; also F. Barnard, in "An Autumn Manoeuvre" (280), has shown a masterly handling of landscape. J. C. Dollman is again happily represented this year by another of his serio-comic incidents. The scene is a field, with a number of rooks looking very gravely and curiously at one of their number, probably the most daring, suspended by a cord from a wing as a scarecrow, and the title "Don't Care was Hanged," suggests a warning to all of defiant disposition. Edwin Ellis sends one of his bold and lucid studies of coast scenery (333), and we notice another contribution by the same school in J. White's "The Miller's Daughter." Mr. R. W. Allan's "Santa Giorgio Maggiore, Venice," is a bright piece of sunlight and colour, and in opposition, T. J. Watson's "Birch Trees" (364), is sombre and greyish in tone. Some solid painting is given in A. de Bréanski's "Quarry Woods, Marlow"; and we cannot omit to mention F. Hamilton Jackson's "Lorethe Pilgrim," as one of the few essays in ideal composition. There are many other

works of genuine merit to be found on the walls which will make the gallery worth a visit by all admirers of painting.

THE WATER QUESTION.—XXII.

SERVICE RESERVOIRS.

A SERVICE reservoir acts as a pressure regulator. It would be inconvenient to connect the service-pipes of the distribution directly with the main pipe which conveys the water from the storage reservoir: it might be necessary to shut off the water at the reservoir for a day or two for repair of the conduit pipe or other purpose, and another inconvenience would be that the pressure due to the height of the column could not be economically made use of; the pressure would be least when most wanted. It is a common occurrence that during the busy hours of the day twice as much water per hour is used as the average hourly quantity, and at those times the velocity in the main would be doubled and the loss of head increased four times, and the serviceable pressure proportionately reduced. The same thing occurs in the distributing main and service pipes in connection with a service reservoir, but with this difference—that, the velocity in them being less, there is less absolute loss of pressure; doubling the smaller velocity and squaring it for its effect does not produce much absolute loss of head. This excessive loss of pressure at the place where the water is to be used is avoided by interposing a service reservoir in which the flow of water expands over an area, and stands nearly at the same height at all times. This evenness of pressure is a practical advantage, although, no doubt, greater pressure would be obtained without the interposition of the service reservoir if but little water were being drawn from the pipes, and if the main conduit were a pipe laid below the hydraulic gradient. For any purpose for which the water would need to be shut off at the storage reservoir, such as the connection of a branch or the repair of the main, 48 hours would probably be time enough, for emptying the main, doing the work, and refilling the main, and in the following remarks it will be assumed that the service reservoir is to hold two days' supply of water. A system has been in a few cases adopted of making very large service reservoirs, where the ground is sufficiently favourable, and thus increasing the storage capacity of the works materially, the form of the ground in these cases being such as to admit of water being impounded by an embankment on one or two sides of the site, or it may be partly on a third side; but usually there is little choice of situation for a service reservoir, its primary necessity being height, with reference on the one hand to the height of the highest ground to be supplied, and on the other to the height of the storage reservoir, the dimensions of the conduit and conduit pipe being made accordingly. The situation of a service reservoir being thus almost rigidly fixed, it is dug out of the ground for the most part, and the excavated earth embankled round it. The four essential features of a supply of water by gravitation are the storage reservoir, the conduit, the service reservoir, and the distributing main and service pipes. Filtration forms a fifth when it is necessary.

Where the supply of water in bulk may be undertaken in connection with the regulation of flood waters, the question of authority divides itself between the landowner on the one hand, and the local sanitary authority on the other, or it may be several local sanitary authorities in each case. The distribution of the water, and its filtration, if necessary, must be with the sanitary authority, but the service reservoir should be made by the reservoir authority

as distinct from the distribution authority, and the sanitary authority would take the water from the service reservoir at a price per 1,000 gallons or per million gallons. Near populous places, where there is usually excessive dust and smoke in the atmosphere, water for drinking cannot properly be exposed, and each sanitary authority would construct a covered service tank, into which the water would flow from the service reservoir. One service reservoir might suffice for several covered service tanks, which, in some cases, might belong to different local sanitary authorities, whether urban, as local boards, or rural, as boards of guardians. Whether one or several sanitary authorities take water from the service reservoir, each would lay a distributing main between the covered service tank and the service reservoir, and the service pipes in connection with it. Adjoining the service reservoir would be a measuring tank for each sanitary authority, in which would be the gauge, open to inspection, and so arranged as to give the quantity of water agreed upon from time to time up to a certain maximum. The use of the service tank at the end of the distributing main would be to receive the excess of water not used, and to contain a day's supply in case of its being necessary to shut off the water at the service reservoir, of which notice could always be given so as to have the tank full. By the continued record of the state of the service tank it would be seen whether more water were being taken than was used, and it should be a condition of the agreement between the sanitary authority and the reservoir authority that the quantity may be varied from year to year as circumstances require, within a certain maximum. This, no doubt, would throw an onus upon the reservoir authority, but only a proper one, as being the dispenser of the water, and being able to estimate the proper provision to be made for present and prospective needs independently of any estimate made by the sanitary authorities.

Amongst the varying levels at which places to be supplied with water are situated in respect of any storage reservoir, three may be taken for example in which the covered service tanks, A, B, and C, would be at such levels that the highest would be about 100ft. below the lowest level to which the water in the reservoir would be drawn down, and if the population of the three places or districts be 30,000 in all, there would be required for a full supply 750,000 gallons a day. It would be a moderate view of the circumstances to assume that within an average distance of three miles of the three places a service reservoir might be made on ground sufficiently high to command them all, and that the water may be impounded at the height named within a distance of seven miles from the service reservoir. The height of the service reservoir in such a case would be at about the mean height between the covered service tanks and the lowest water level of the storage reservoir. There would then be about 16ft. or 17ft. fall per mile in the distributing main, and 5ft. per mile in the conduit. This would be sufficient if the water were carried along the hill sides, but if any considerable length of low ground intervened, requiring to be crossed by an iron pipe, the total fall of the conduit could be a little increased and the fall of the distributing mains as much reduced.

An open reservoir should be at least 14ft. or 15ft. deep. The rays of the sun act through any shallow and stagnant water upon the bottom, and cause the growth of vegetation and insects. If the service reservoir in question were required to hold 1,500,000 gallons, or 240,000 cubic feet, being two days' supply, and it be made 15ft. deep, the water area at the mean depth would be 16,000 square feet, and if it were

made square it would be, at that depth, 127ft. square. According to the nature of the ground, the slopes may be from $1\frac{1}{2}$ to 1 to 2 to 1. Let it be assumed that they are 2 to 1 throughout, both in the excavation and embankments, and that the top of these is 2ft. above the top water-level. The reservoir would then be at the top 165ft. square. The top of each bank may be 6ft. wide, except on the lower side, where, indeed, the width may be the same and the slope the same, but divided by a level bench of such width that the bulk of earth in the lower bank would, if continued in one slope, make the top width 9ft. Here we have no puddle trench, and to make the reservoir watertight, the puddle—if puddle be used—is continued across the floor and up the slopes of the excavation, and along the surface of the ground to meet and join with the puddle-walls raised in the centre-line of the embankments. The floor-puddle may be 2ft. thick if well made, and the wall-puddle should be at the bottom as thick as will allow the top to be finished 3ft. or 4ft. thick, with a gradual reduction in the thickness of 1ft. in each 6ft. in height. The surface of the floor-puddle, and that upon the slopes, should be covered with broken stone or gravel, not less than 6in. in thickness, which may be continued up the slopes of the embankment to the top of the reservoir. This hardly forms of itself a sufficient protection of the puddle against the action of the water upon it, but if the interstices are filled with sand it does so. There is but little difference between this and concrete for this purpose. But to provide a surface which can be swept, brick-on-edge paving is added, or two courses of bricks laid flat.

If the water is not to be filtered, it is necessary that it should pass through fine wire-gauze strainers in going out of the reservoir. To hold these and the valves through which the water would pass, a structure of masonry is built.

The strainers are of copper wire, 40 to the inch; but as these, being of so fine a mesh, would too soon require removal if not protected, strainers of a mesh less fine, about 20 to the inch, are placed in front of them, and a double set of grooves is provided for these, so that before one set is removed the other may be inserted. The screens are removed and washed as occasion requires, being for that purpose and for strength made in small rectangular frames of wood, inserted in a larger frame which can be lifted out bodily, these being set one upon another to the height required.

The top soil, before the excavation is begun, would be taken off and reserved outside for soiling the slopes of the banks. The tops of the banks would be formed as footpaths, with gravel or any clean material, and formed with a transverse inclination away from the reservoir. The outside of the puddle-wall should be protected from rats by a facing of concrete, or else the earth may be mixed with lime in the proportion of about 10 to 1, and watered for a yard in width outside the puddle-wall, and this should be extended along the surface of the ground for some part, if not the whole, of the seat of the outer part of the embankment. In the case of a high embankment, as of a storage reservoir, this protection is not necessary, because the distance from the outside to the puddle-wall is too great to be burrowed, but in small service reservoirs the puddle should be protected.

In many situations where it would be proper to construct a service reservoir, it would be difficult to procure clay for puddle within any short distance, and it might, at the same time, be easy to procure materials for concrete. In that case the reservoir might be made watertight, without puddle, by the use of concrete made specially with that view, that is, with plenty of filling,

both sand and lime, or sand and cement; but if good blue lias lime can be procured at a less price than cement, it will be preferable to use lime, the quantity being increased in the ratio that the price of cement bears to that of lime; and the thickness of concrete may be less than that required of puddle; and, reckoning the thickness of puddle and its covering together, this is a considerable reduction of the thickness of materials required for the bottom of the reservoir, and saves excavation to the extent of about half the difference of the cubic contents. If, however, there is the slightest reason to fear a movement of the ground, however slight or partial in its extent after the reservoir has been made and filled, puddle will be preferable to concrete as being less rigid. At the same time the longitudinal tenacity of concrete may be a favourable property in the opposite respect. The earth would be wheeled out, or carted out, and put into the banks in thin layers not more than 6 in. in thickness, and consolidated by hard ramming, and, if sand, watered at the same time. A sand bank made in wet weather is very much superior to one made in dry weather. If the banks be wholly of sand the puddle walls should be of greater thickness than is otherwise necessary, unless they be faced with clayey material, or with limed earth to prevent the moisture of the puddle being absorbed by the banks. Service reservoirs, larger and deeper than the one of this example, have been made on ground containing nothing but sand, and with the strength-dimensions here stated, stand firm and watertight; but ground containing sand, clay, and stone shale mixed is preferable, if the clay be not in excess. Instead of the expensive brick-paving of the inside of the reservoir, a facing of Portland cement on concrete would be almost equally good, and considerably less expensive.

A particularly good fence is necessary round the foot of the slopes. Post and rail is good enough for a storage reservoir, but not for this, and the fence should be far enough from the foot of the slope to allow a cart-way all round, and a piece of land should be inclosed near the outlet of the reservoir for stores and other purposes.

ARCHITECTURAL ASSOCIATION.

THE second ordinary meeting of the present session was held on Friday evening—the President, Mr. Aston Webb, in the chair. The following 62 new members were selected:—M. Collins, C. S. Cornish, F. Ward, F. W. Lane, A. E. S. Whitelock, F. A. Dry, F. A. R. Willey, J. Napier Hamilton, Stuart H. Davies, G. H. Oakley, L. Dawson, F. A. Huntley, F. Macey, J. E. Newberry, W. R. Lawrence, W. D. Duffett, C. Turner, R. Kershaw, A. O. Breeds, C. J. Clarke, P. J. Burne, F. E. Masey, J. J. Wood, F. J. Webb, C. S. Meadway, B. Potter, N. J. Stanger, G. G. Wallace, P. H. Watson, C. F. Moxon, E. J. Stow, E. P. Tucker, Levi Lunn, J. Shepherdson, W. J. Roberts, G. E. Holman, C. R. H. Tyndall, G. P. K. Young, H. C. Chevalier, R. W. Paul, W. R. Crewe, A. G. Griffith, H. Whittles, J. M. Hatfield, R. J. Thomson, E. H. Dance, W. C. Rea, V. E. Bigsby, E. D. Hoyland, P. P. Brown, C. J. Knight, H. O. Jackson, F. L. Sweet, T. F. Pryce, H. C. Brushfield, J. M. Keith, W. H. Closson, A. Turner, J. Innes Murray, J. C. Waghorn, W. E. Synnington, and W. A. Alderton.

THE NEW EXAMINATION AND WHAT IT INVOLVES.

A paper on this subject, which we reproduce in full on p. 718, was then read by Professor T. ROGER SMITH.

At the close of the paper, the PRESIDENT heartily congratulated Mr. Roger Smith, a past-president of the Association, in the name of the members, on his recent appointment at University College, adding that at the present moment, the paper was most valuable to all young architects. The subject of the

Institute examinations had been clearly and concisely brought before them, and they had had the great advantage of ascertaining from one who enjoyed exceptional opportunities of knowing the facts, particulars as to the kind of examination and the probable mode of awarding marks. The practical failure, as he might almost call it, of the previous voluntary examinations, made them rather more dubious as to the success of the present scheme; but the Association had endeavoured to assist it by starting preparatory lectures, which thus far he was pleased to state had been very largely attended. It was to be regretted that the first of the new examinations would be held so early as March next, before the courses at the Association and University and King's Colleges were concluded, and it was a question whether it would not be advantageous to omit the examination. The high standard which had been set by the lecturer, would, if adhered to, largely increase the value of the certificate, while it added to the responsibility of the examiners.

Mr. A. L. PITE said the younger men had been whipped up to this examination, but now that the syllabus was published it did not seem very grand. He trusted that the fatherly Institute in its scheme would not simply test them as budding building surveyors, but as future artists, and that in the marking of papers some (say) 500 marks would be awarded to art qualifications and 100 to mere construction, for the two great qualities of great architects had been enthusiasm and imagination. He suggested a preliminary examination for those joining the Association, and proposed a vote of thanks to Prof. Roger Smith, who had always shown himself ready to give a helping hand to young men.

Mr. BLASHILL seconded the motion, and said it was right to explain that the suggestion of a compulsory examination was not due to a committee, but to their Past-President, Mr. Douglass Mathews. He had been gratified that the members had responded to the proposal to form classes so much more numerous than had been expected. In his own class he felt the great responsibility thus laid upon him, and how inadequate the time was to the purpose. For the latter reason, he should aim at making it rather a reference to authorities where information could be gained, than an attempt to compress the information itself into the hour, for it was far more useful to the student to know where he could continue his studies than to gain some one fact. It was also highly important that the student should study and sketch buildings in progress and completed. Mr. Pite's suggestion that an examination should be passed by those joining the Association, was too much like telling a man he must learn to swim before entering the water; the very purpose of the Association was mutual help and instruction. Nor could he see why construction should be considered of less importance than art; many men could draw pretty pictures of buildings which careful inspection would show to be impracticable, as they transgressed the rules of construction. The lecturer had mentioned that the subject of the examination was to show that men were fit to act as architects. Let them not forget that it would also show if they were qualified to be assistants, for such excellent work and many important, responsible duties were performed by confidential assistants, and the filling of such a position was a useful training to the future architect.

Mr. SIDNEY VACHER expressed a hope that the certificate of examination would be regarded by practising architects as of some weight in engaging architects; as otherwise, it would be very discouraging to those entering for it. His own experience, when seeking a situation as assistant, was that employers paid little or no attention to prize-work, for when he tried to get a fresh situation he took with him a roll of diploma drawings, which had gained first prizes in the classes of construction and design, the silver medal of the Academy, and a certificate of having passed the first portion of the voluntary examination. No architect would take the trouble to look at his work, or paid any attention to it, till he got to the last name but one on his list, that of Mr. Street, who examined his work and engaged him. He should like to know if the examiners would deal hardly or easily with the ambitious young men who aimed at a "new style," and inserted into their works funny little "bits," picked up apparently in

the gutter. He trusted more attention would be given to construction than to such attempts at "art."

Mr. S. STEWARD SMITH, of Reading, observed that provincial students, who could not attend the classes and college courses in London, would be thankful to know what books they ought to study to prepare for the examinations. He also asked whether the examiners would prefer the rough sketches as drawn, or to have them worked up and finished.

Mr. HARDCASTLE suggested that any student who took an interest in his work would be certain to have devoted more attention to one branch of study than to others. It would be desirable to know if the Institute examiners would require marks to be pretty equally allotted all round in a certain proportion, or if they would pass a candidate who made a total of 600 marks, even if he failed in some one or two sub-sections. The new examinations would be beneficial in drawing their studies into a focus and in giving a stimulus to work. They offered an absolute prize, which all could gain, in lieu of the competitive prize, which only one could carry off, and so afforded a more general encouragement to students.

A MEMBER asked how a pupil who was closely employed all day in an office could gain practical experience in constructional matters? At the Saturday afternoon visits the workmen had all left off, and they saw nothing of the actual operations.

Mr. DOUGLASS MATHEWS held that the Association was not, strictly speaking, an educational body, but one of mutual self-help, and that, therefore, the class lecturers were right in proposing to give skeleton rather than exhaustive addresses. It was not, in his judgment, desirable that men should enter both courses of classes, or that they should aim at doing too much at once. Indeed, students who had just taken up the subject, would do well not to enter for the examination for a year or two, so as to get thoroughly grounded and prepared. The aim of the promoters was not, he thought, to show that Mr. So-and-so had passed the examination, and was, therefore, entitled to practise as a thoroughly able man. Still, at some future day, if shown to be necessary, the issue of a diploma might follow. He could not agree with the President that the voluntary examinations had been a failure, although he admitted that they had not been largely availed of, because there was a want of incentive to undergo them. Since this inducement was now held out in the Associateship of the Institute, there was no reason why the compulsory scheme should not be a success.

Professor ROGER SMITH, in responding to the vote of thanks, said it could hardly be expected that the examinations should be suspended on the ground that students were not prepared. Notice had been given of the compulsory scheme for two years past, and there had been ample time for preparation. Still, he agreed with the last speaker, that it would be wiser for those who had but just taken the matter up, not to enter till the second or third examination. The question had been asked as to whether the certificate would imply a fitness to practise; that was, whether the standard to be set would be so high as to act as a diploma. In itself, no doubt, the examination simply professed to ascertain the qualification of a man for admission into the central society of the profession, but the public would soon jump at the conclusion that a man's ability to act as an architect was testified to by his having passed. That feeling was held in committee, and would probably influence, to some extent, the action of the examiners. At one time, some doubt might have existed as to whether any body of men could examine works in many styles; but in these latitudinarian days there would be less difficulty in getting an impartial judgment from examiners as to designs in any style, Greek, Gothic, Italian, or Queen Anne, than would have been possible twenty, or even fifteen years, since. Mr. Vacher had raised a question as to the chances of eccentric work. He did not think an unusual design would necessarily be rejected, but it would, probably, make the examining board more strict in their requirements as to the constructional and other sections. As to the difficulties experienced by the same gentleman in seeking work, he hoped it was because he tried at a slack time, and not because architects

were, as a rule, indifferent to the value of prize work. With most men of good position, the passing of an examination should be a valuable recommendation in an applicant's favour. As to the probationary work to be submitted, the best possible would be a complete set of drawings, executed by the candidate, of a work carried out under his supervision. Sketches should be sent in in the rough, and not re-worked. He would recommend classes of books, rather than any special volume, to those who studied at home, and these would be works on the history of the art and those dealing with construction. It was more desirable they should get up some one subject thoroughly, than try to learn up the whole of Gwilt's "Encyclopædia," for example, for as the student pursued any special subject, such as one of those treated of in Scott's Academy Lectures, he would find that it had ramifications, which, if followed out, would lead to a connection with what he knew on every branch of architectural study. The marks at the examination would be given as a whole, and not equally proportioned, and thus the man thoroughly qualified in one subject would obtain credit for that special knowledge. He had been asked how the hard-worked pupil could see a building in course of construction. He would remind the questioner, that, even if his luncheon time was too short for the purpose, few architects' offices opened before 9 a.m., whereas most building operations commenced by 6 or 6.30 a.m., and, therefore, to the earnest worker, there were two valuable hours' instruction to be gained. There were easy means of making friends with a foreman or artisan, and they might depend upon it that every man liked to talk about that which he thoroughly understood. In conclusion, Mr. Smith expressed his belief that the examination would succeed.

THE NEW COMPULSORY ARCHITECTURAL EXAMINATION, AND WHAT IT INVOLVES.*

THERE are, I think, few architectural matters which cannot be better understood by reference to their history, than if you regard them simply as they appear at the present day. Though an examination which has never yet taken place cannot exactly boast of a history, still a little retrospect of the causes which led up to it may help us in understanding its scope. As far back as the oldest member present can remember, that is to say, in the days of Lyons' Inn Hall, the desirability of a diploma for architects, or at any rate of an examination, such as the members of several other licensed and scientific professions have to pass, has been dwelt upon in this Association—and the need of it has always been felt by a certain number of the members of the Institute. Eventually Professor Hayter Lewis, when he was Secretary of the Institute, procured the appointment of a committee to consider this question and draw up a scheme for an entirely Voluntary Examination. The work of that committee was, a good deal of it, done by Mr. Arthur Ashpitel, Mr. John Papworth, Professor Lewis and myself, and during part of our deliberations we had the co-operation of Professor Kerr. The Institute, as a body, I must confess, looked upon the scheme with coldness, perhaps with some jealousy, and to disarm this jealousy we were compelled to accept limitations which hampered it not a little. No kind of distinction or reward, not even a certificate, was to be gained by passing, no privilege or grade, or title was to be accorded to those who passed. The first examination took place in the year 1863, and it is melancholy to think that of those who conducted it, I am the only survivor. The examiners were Sir Gilbert Scott, Sir Digby Wyatt, and Mr. Arthur Ashpitel, the Moderators, Mr. John W. Papworth and myself. The result was that eight candidates passed in the class of Proficiency, and in the following year seven, with the addition of two in the class of Distinction, for we had two classes to begin with, and altogether the honour of Distinction was gained by three candidates, all of them well known members of this Association, Mr. R. Philip Speers, Mr. R. K. Bayne, and Mr. T. H. Watson. As years went on this examination languished

mainly, I believe, because it led to nothing; and modifications were introduced with the idea of making it more attractive to students; the most important changes being the abolition of the class of Distinction—the introduction of a Preliminary Examination, the division of the Proficiency Examination into two portions, which a candidate might take in different places—some modifications of the subjects of Examinations, and last, but not least, the grant of a certificate, and, under some limitations, of the title of Graduate of the Institute. These changes seemed to work well, and the results of the Voluntary Examinations, before and after this introduction may be summarised as follows:—Ten Examinations have been held during 18 years. Three students have passed in Distinction, 43 in Proficiency, and 52 in the Preliminary Examination, making a total of 93 successful candidates, whose names you will find in the Brown Book, and many of whom you will recognise as having been in other ways successful since. I must now take a glance into the past, and remind you that some years ago a Committee was appointed, at the suggestion of Mr. Horace Jones, to consider what steps could be taken to advance the welfare of the Institute. That Committee's report was not agreed to by the general body mainly, on the ground that it advocated the grant of a new charter, and a second Committee, which was thereupon appointed, considered the matter afresh. Among the recommendations which it made, this Committee reported that after a certain date all Associates of the Institute ought to pass an Examination. The various recommendations of this report were agreed to substantially as they stood, and the changes recommended were adopted. The Examination about to take place is one of these changes, many of which appear to have been of essential service to the Institute, and through it to the Profession. I propose now to give you some idea of what we may suppose to be intended by the establishment of this Examination, and of what the Examination itself will embrace. We may safely put the intention of the Institute as being to render the Associateship of their body, a guarantee that the Associate has proved his fitness to be entrusted with work, so far as that fitness can be ascertained by an Examination. At present a man is admitted an Associate because nothing is known against him, and something has been said in his favour; but it is not incumbent on him, and indeed would not be very possible for him to prove to the satisfaction of the Council who receive his nomination or of the general body who elect him, that he is properly qualified; and accordingly, though Associateship of the Institute has a very considerable value, it is not at all so serviceable to those who have obtained it in the way of giving them standing in the eyes of the public as it might be, and as we may hope that in a few years it will be. This being so, the course of examination must be taken as embodying a kind of standard of the qualifications of an architect, and, as such, is a document of no small interest. The draft of it was prepared with great pains and care by a committee on which several members of the Association had seats, it was finally brought to its present shape by the Council of the Institute, and it was passed by the general body, so that among the matters which are involved in the Examination, we may fairly take this authoritative publication of an architectural standard of qualifications as the fairest. A competent architect, then, must be able to design and draw out a building complete, including perspective, details and ornament, and he must be able to plan and work out a scheme for appropriating a given set to a special purpose. He must be able to write a specification and prepare an estimate. He must also know something of the conditions usually appended to contracts. As far as construction goes, he must be familiar with building materials and how to use them, and calculate the strains upon them. He must know how to drain his buildings, and should have some knowledge of what to do in case of failure and accident. Lastly, as regards art, he should have a general knowledge of the history of our art, and be tolerably familiar with one small portion of that history, and he should possess sufficient acquaintance with the mouldings, features and ornaments of some one style, to be able to use them with correctness in his designs, and to draw them from memory. I do not think that less than this can reasonably

be expected of architects who begin practice, in the interests of the public and the profession alike; and should the examination be so conducted as to bring these qualifications to a fair test, the architectural profession cannot fail to reap great benefit. I have recently, before a different audience, given some account of the actual course of examination as proposed in the Institute's programme, and as that must be done here also, you will, I dare say, pardon me if here and there I quote a phrase from the opening lecture of the courses at the University College, the lecture* just referred to; though I may as well say at once that I propose to examine the course of examination here at much greater length than was requisite in that lecture. The obligatory preliminary work consists of a set of plans with a perspective drawing, a sheet of details, and an ornament. This requirement is, of course, intended to elicit practical skill in architecture generally, and in handling drawing materials and making drawings. Work done as a student, such, for example, as sketches from ancient buildings, notes or essays, may be also submitted at the option of a candidate. This affords an excellent opportunity for a student who has really made studies to show them; and though it does not appear that marks are directly allotted to the preliminary work, there can hardly be a doubt that good preliminary work will tell in a student's favour, for example, it will be likely to induce the examiner to turn the *vis-à-vis* examination into a direction towards which his preliminary studies have pointed. The first subject for examination is the History of Architecture, taking a general view of a wide field and an examination in some detail of a single division of the subject. It is a matter for congratulation that History is thus required, for its value is, I believe, very much underrated. To a certain extent a knowledge of the History of Architecture is part of the education of an architect, as distinguished from his mere instruction; and it is a characteristic of the present day, that few students, especially young ones, will tolerate any subject of tuition which is to be pursued solely for the purpose of training, expanding, and informing their minds. They want something that will pay. Now that the history of architecture will pay to the extent of 100 marks out of the 600 obtainable, I hope many will give some attention to it, and will, to that extent, get educated in spite of themselves. The answers to this paper are to be illustrated by sketches, and, no doubt, the judges will be much influenced by really good sketches.

The second subject of examination is one intended to show that the student has mastered some one Style sufficiently to give him a command over its forms and features, knows it, in fact, so that he could use it on a building without committing gross errors. This subject is largely a test of practice and drawing, and private study, but there is nothing in which the junior class of design could be more serviceable than in giving the members some idea of what is meant by an accurate use of some one style: though, of course, in preparing for examination careful private study will be required in addition to attendance at that class. The best preparation by far, is measuring, sketching and drawing out some existing example or examples of the style selected. Even a modern example from the hand of a good architect would be a more instructive study than a book or an engraving. To this subject 75 marks are allotted. The third division is Materials and Construction with Sanitary Science, and I need hardly add, I hope, that practical as well as theoretical acquaintance with these subjects will be necessary, in order to satisfy practical examiners, and must be sought on the works to which the student has access. This group of practical subjects to which two papers will be devoted—engrosses one third of the marks and occupies one third of the time which is allotted to paper work. It is therefore manifestly the most important of the whole, and one in which I venture to think the examiners will be disposed to be more strict than in other cases when marking other papers. The principal building materials can be understood best by those who have experience of their use, and have ripened and extended that experience by reading books, attending classes, making inquiries for themselves.

* A paper read before the Architectural Association by Professor F. Russell Smith, on Nov. 29, 1881. (See p. 717.)

* See verbatim reports of the lecture in the BUILDING NEWS for Oct. 11 and 21, 1881, pp. 488 and 522 of current vol.

examining, and when possible collecting specimens; and witnessing experiments when testing is going forward. "The principles of construction as applied," are words in the Programme which seem to cover the theory and practice of building, and the student will have to pursue both. Drainage and sanitary requirements are also named. In this we are all in the position of new brooms, and probably a manifest want of familiarity with the modern ways of executing what is called sanitary plumbing and drainage, would induce the examiners to make a clean sweep of the candidate's chances. The application of formulae will, in all probability not be pushed far, but it is very desirable that what is done should be right. As there is no preliminary examination, and no subject that is not a strictly professional subject is taken up, the examiners may possibly afford an opportunity for those candidates who are good mathematicians to show their skill by including two or three difficult questions. No doubt the moderately trained man will be wise enough to let these questions alone if such are set; and the mathematicians will be heartily glad of them. Considering the heavy risks that attend the failure or fall of buildings, it is a very good thing that this curriculum includes what I may call their Pathology. This the aspirant to associateship cannot learn from any books that I know of; but only from seeing buildings that are dangerous and watching how they are dealt with. It is very desirable to get some notion of how foundations fail, how brickwork fails, how timber leaks or shrinks, or rots, and how masonry yields; and perhaps there is no place which affords more opportunities for the study of these things in old buildings and new than poor leasehold London, founded on clay, run up in haste, with indifferent materials, and too often no professional supervision beyond that of the district surveyor, and no specification save the Building Act.

The fourth subject is Planning for a special purpose; it is one more calculated than some of the others to show that the candidate is fitted by nature and training to practise as an architect. No preparation for this paper will be better than making designs in one or two classes of design; but the various opportunities offered by public competitions, by the prizes given in some of the Professional journals, and by competing for the Institute prizes, and those of this Association, each and all offer good occasions for drawing out and stimulating powers of design. No man is a born planner, and practice is as necessary in this as in any part of the curriculum, perhaps more so. To this subject 75 marks out of 600 are allotted. The fifth subject is writing Specifications and Estimating, and here a candidate can make 125 marks, though, as the time allowed is rather disproportionately short, he will probably be unable to do as much as he would like in the way of answering questions. My own impression is, that specifications will be more thought of than estimating, and, indeed, the questions are described so as to lead one to expect that only a general acquaintance with how to Estimate will be required, while an actual bit of Specifying has to be done—and should be well done. The last subject is so much of Professional Practice as is involved in the general conditions usually appended to a contract. Of course, this must be interpreted as meaning not merely familiarity with the usual clauses, but with the purposes which each is meant to serve, and the dangers and disappointments which each is intended to avert. It does not seem that great stress will be laid on this subject, important though it be, as only 25 marks are allotted to it. The work thus far is done by means of written or drawn answers to printed questions; i.e., is paper-work only, and it takes up three days—Tuesday, Wednesday, and Thursday—the candidates having six and a half hours' work on each day. The examiners, meantime, will give such consideration as they can in the time to the work of each student taken as a whole, with the addition of his preliminary work, and will so prepare themselves for the *viva voce* examination. This, though no doubt actually very formidable to some young men, should really be regarded as a most valuable feature of the scheme. The candidate who has really done something wrong—as, for example, one who had attempted to send as preliminary work something drawn by another hand (if any one ever was mean enough to try that)—might

expect to have a bad time of it, as the inconsistency between his preliminary work and his answers would probably have appeared, and he would be pushed hard, and deservedly; but to no student who has honestly prepared himself, and tried to do his best, can the oral examination be other than an advantage. It must not be forgotten that, at any rate in the early examinations, the desire of the examining board will be likely to be much more to let men in than to keep them out; and in scanning the work of a doubtful candidate, there will be sure to be a disposition to try to find out the points where he is strong, and give him opportunities of answering some questions about them than to push him too hard where he has shown signs of weakness. I beg strongly to commend this view to intending candidates who are fairly prepared, and to advise them to look upon the oral examination as their best friend, and not as diminishing their chances of success. The examiners sitting round the table will certainly not desire to admit the unworthy, but I am very sure they will do their best to discover and bring out the worth of the worthy. Finally, the examiners will have to adjudge marks to the work done. The system they will pursue is of course for themselves to determine, but it will no doubt be a uniform one. They will, in all probability, give no marks at all to paragraphs full of irrelevant information, which the student had in his head or had committed to memory, but which are not answers to the questions. On the other hand, correct, exact replies, just to the point, even if brief, will be sure to be marked high. Illustrative sketches, if well done, ought to command good marks; and any answer, be it drawing or be it writing, that is thoroughly right and thoroughly complete, no doubt will earn all the marks it will deserve. On most systems of marking it would be possible for thoroughly correct answers to all the questions to obtain more than the maximum number. On the least favourable plan, the full maximum must be possible. The limit which a candidate must obtain in order to pass is one half this number, gained not necessarily in each subject, but as the candidate best can; and any moderately good set of answers ought to reach this. If the half is very nearly approached, though not reached, it is to be presumed that the examiners will recur to any memorandum they may have kept of the oral examination, and will re-examine the preliminary work in order to see if they can fairly increase the number of marks in any subject; and if, after this reconsideration, which I know will be done with a disposition to look into the candidate's merits fairly, and perhaps favourably rather than harshly, the examiners feel bound to reject a candidate, he may be pretty sure that he has not yet properly prepared himself for practice, and that by continuing his studies he will be doing nothing more than that which it is necessary should be done in order that he may, with safety both to himself and to those who may employ him, practise as an architect. Perhaps it is right that I should add that, owing to my position at University College, I am, fortunately for myself, not eligible to serve as an examiner, and that in what I have just said I must not be understood as pledging any of the examiners to any special course; but only as speaking from some experience in the voluntary and other examinations, and from an intimate knowledge of the circumstances.

(To be continued.)

LECTURES ON HORTICULTURAL BUILDINGS AT THE CRYSTAL PALACE.—III.

(Concluded from page 687.)

THE last of the course of illustrated lectures to the students of the Crystal Palace School of Gardening and the public was delivered by Mr. F. A. Pawkes (author of "Horticultural Buildings") on Wednesday, Nov. 30th.

Directing the first portion of his remarks to the subject of "Show-houses," the lecturer said that several points regarding these must be kept in view: 1st, a conservatory or show-house must be regarded as one of the reception-rooms in the dwelling; 2nd, we must endeavour to make it approximate architecturally, both within and outside, to the other portion of the dwelling; 3rd, this being so, we must regard the functions of growing and

showing as quite separate. In a growing-house the glass roof must be brought as near the plants as possible; in a show-house high eaves are usually necessary. In a growing-house 5ft. is a very general height; in a showing-house they may frequently be with advantage 10ft. high. The site for a show-house is generally determined by the situation of access from drawing-room, and may be where no sunlight can reach it. It must have scantling of larger dimensions and more obtrusive than that for a growing-house. If gardeners recognised this distinction of purpose, they would not so unhesitatingly condemn many designs for conservatories as perfectly unfit, because the designers showed too high a roof or obstructed the light by sash-bars, a little cathedral glass, or a gable. In designing such buildings considerable regard must be paid to artistic qualities, without forgetting its purpose, and some general principles can be laid down. Where possible, the floor-level of conservatory should be on higher level than that of garden by a step or two. This, however, is practically determined by the next and important point that a conservatory floor should be practically on the same level as the floor of dwelling-house communicating with it, the fall not being greater than 2in. Avoid valley gutters next the wall of dwelling-house; if you cannot, let the gutter be a wide one, on which a man can easily walk. Let the roof of conservatory meet the brickwork of dwelling, either upward or at right angles. Have a short corridor between dwelling and conservatory, so that two sets of doors may efficiently prevent any moist air entering the house. Avoid circular work and complicated roofs—a simple gable may be treated effectively. Sufficient interest should be created by broad lines without having recourse to fussy details or meretricious ornament. If you have a lean-to roof and wish to introduce a gable, let the latter project, if only for a few inches; better still, let the gable be emphasised by rising above the eaves. Sometimes a semi-octagonal roof may be thrown out from another roof; but it should be a true semi-octagon, or a flat, weak appearance will be the result. Should a lantern-roof be used, if the end of roof be octagonal, the corresponding end of lantern must be of the same form. A roof of 30° pitch forms part of a hexagon, and may be advantageously employed in producing a pleasing perspective. In a conservatory, the distance apart of the principals depends upon the size and proportion of the structure, but 5ft. is a very convenient width for bays between mullions. These spaces may often be filled up by a transome with transome light over, and beneath two framed lights, opening casement fashion. The light over transome may be filled up with tinted cathedral glass, lead glazed, or perhaps small panes. If the height to the eaves be 10ft., composed of 2ft. wall, 6ft. casement, and 2ft. transome light, and one width of the casement lights about 2ft. 6in., then whenever doors occur their upper part may be treated like the casements and occupy the same space, the tops of the doors coming up to the transome. If, on the other hand, the height to the eaves be only about 8ft., made up of 2ft. wall, 4ft. 6in. casement, 1ft. 6in. transome light, then when doors occur they may rise above the transome and reach the eaves.

So far as the interior treatment of conservatories is concerned, the intimation given that a conservatory should be regarded as one of the reception-rooms of the dwelling-house, will have prepared the way for my advice to avoid fitting up the interior with staging of any kind. Let there be beds and borders, but do not let any supports for the plants be seen if possible. Let there be an ample paved space—not a mere path, but a space so that a table and chair or two may be placed in it. Let the conservatory be regarded more as a lounge than as a mere place to walk round. This space may be paved with marble mosaic, or encaustic tiles. If the size and nature of the conservatory will admit, then rockwork, a fountain, or even a little sculpture, may find a place in it. Baskets of hanging foliage look pretty; bare walls may have creepers upon them, and if staging round the sides or over hot-water pipes be employed, then the space under staging may be hidden by wood diagonal trellis. If one side of a large conservatory be the wall of the dwelling-house, and there be means for easily effecting it, an open fireplace against such a wall would not be unsightly. A grass mat or two thrown down here and there, and a

parrot on a stand, might form pleasing features. Sometimes there may happen to be an awkward recess in the brickwork; of this an aviary might be formed. If shading be required in a conservatory, the vertical sashes may very well have South African grass curtains, hung in front of them. This material is not affected by sun or damp, and looks artistic and suitable. There are various ways of heating horticultural buildings; by fermenting mat-ricks, flues, hot air, stoves, gas-stoves, lamps, high-pressure, hot-water, steam and low-pressure hot water. Fermenting materials by themselves are perfectly insufficient and inefficient. Flues are liable to promote excessive heat as well as concentration of heat; they sometimes admit the products of combustion to the plants, and cannot be manipulated with sufficient ease. Hot-air stoves are liable to much the same objections as flues. Gas-stoves, in addition to other fatal objections, are very costly to keep in work. Lamps are out of the question, except in the very smallest and rudest of green-houses. High-pressure hot water and steam are both dangerous, and both concentrate the heat. This leaves us for consideration low-pressure hot water, which provides the most suitable and efficient means yet known for raising the temperature in horticultural buildings. The maximum temperature required in a glass house depends on the amount of piping used; the calculations as to the amount of pipes to secure given temperatures are almost too complicated for mention in a lecture; a few statistics, based on experiment as well as theory, must suffice. The radiating pipes in horticultural buildings are generally 4in. in diameter of cast iron. In conservatories and greenhouses, in which the aim is to keep the frost out, for sheltered lean-to's from 30ft. to 35ft. of 4in. pipe should be used for every 1,000 cubic feet of area in the house; for exposed span-roofed houses, from 35ft. to 40ft. must be employed. In vineries, &c., where the temperature must be from 55° to 65° F., use from 40ft. to 50ft. per 1,000 cubic feet of area in lean-to's, and from 45ft. to 55ft. in spans. In plant-stoves, with temperatures of from 60° to 70° F., use from 50ft. to 60ft. per 1,000 cubic feet of area for lean-to's, and from 55ft. to 65ft. for spans. For forcing-houses, with temperatures of from 65° to 80° F., use from 55ft. to 65ft. per 1,000 cubic feet of area for lean-to's, and from 60ft. to 70ft. for spans. Much must, however, depend upon the aspect and position of house, and the amount of shelter it possesses. It is a good fault to specify rather more pipe than is absolutely necessary, for with low-pressure pipes the radiating surfaces can never attain a high temperature, and the water should never be allowed to reach the boiling-point, or great waste in fuel will take place. The figures just given are for pipes freely exposed in the open air; if it be in trenches covered by gratings 30 per cent. more piping may be allowed. For pipes through beds at bottom heat for cucumbers, allow for a bed 1ft. 6in. wide, two rows of 2in. pipe; 2ft., two rows of 3in. pipe; 3ft. wide, two rows of 4in. pipe; 4ft. wide, three rows of 4in. pipe; 5ft. wide, four rows of 4in. pipe. The air requires to be heated immediately upon its entrance into a house, in order that the cold air may not strike the plants; consequently pipes should be placed near the outer walls, and, if possible, immediately under or in front of the inlet ventilators. At the same time, the heating surfaces must be distributed as much as possible to avoid concentration of heat. Pipes should, therefore, be continued throughout the length of a house, and if it be wide in proportion to length continue across the ends. You may find it necessary to have three, four, six, or even more rows of pipes coupled together at the ends. Where several sets of radiating pipes are required, they can all be fed from one boiler, and worked independently of each other, if a supply-main flow and return are properly used. No dips must be made in the pipes to go under doors, for dips mean arrest of circulation. The more the heating-pipes are exposed to the atmosphere they are required to heat, the more efficiently will they work. As the mains, however, are simply used to convey heat from the boiler to the radiating pipes, they must be so protected as to radiate the maximum amount of heat. Where the mains pass through an open space they may be lagged with felt, silicate cotton, or other non-conductor. When they pass through the ground, lay them in a hollow brick trench, covered in at the top, so that they are sur-

rounded by a quiescent jacket of air. It is thus possible to place the boiler at a considerable distance from its work, although a certain amount of heat is lost in transit, however well the mains are protected. Supply mains must never be less than 2in. diameter, and when the distance is great the diameter may be increased to 3in. or even 4in. All pipes should have a rise of 1in. in every 9ft., to promote circulation and all bends and contractions must be avoided when possible, as they occasion friction. The boiler must be well below its work; the greater the rise in the pipes the more manageable will be the two columns of water which you have to deal, and the easier and quicker the circulation. The valves used are throttles, and these should be provided to the return as well as the flow-pipes, but high-pressure stop-valves are preferable, as being more efficient. If used, however, they must have a full straight unimpeded passage when open, or they will seriously impede the circulation. Provision must be made for the expansion of the water (which in being raised from 40° to 212° F. increases 1-23rd in bulk) by a little cistern; but in practice the expansion never exceeds one-thirtieth, as a boiling temperature is never attained in the pipes. The cistern should be connected with the bottom of the boiler, so as to serve as a source of supply. Soft water should always be used so as to reduce the amount of incrustation. An air outlet must be made at the highest point of each series, and should be at the summit of every rise. It may take the form of a small tube rising 8ft. or 9ft. above the apparatus, where it will be self-acting, or a small tap, which will require attention twice a day. Of joints, the spigot and socket are generally used, indiarubber rings being the best cementing

FIG. 24.

material. Fig. 24 shows a section of indiarubber ring joint A being ring before, and B after insertion between socket and spigot.

In choosing a boiler, recollect that its power primarily depends on the area of heating surface and the description and position of that heating surface. This surface is fully effective only when it is flat and horizontal, and the fire is beneath it. Vertical surfaces are calculated at 50 per cent., if the efficiency and horizontal surfaces beneath the flames are not calculated at all. When instead of the actual flame, merely hot air impinges upon the heating-surface, as in the case of saddle-box boilers, only about one-third of the heating surface is efficient. Each square foot of effective area will heat from 40ft. to 50ft. of 4in. pipe, from 55ft. to 66ft. of 3in. pipe, or from 80ft. to 100ft. of 2in. pipe. For efficient economic heating, you must never put on to a boiler more than about 60 per cent. of the maximum length of pipe which the makers of a boiler guarantee it will heat. Cast-iron boilers are better than those of wrought iron, tubular better than saddle forms, horizontal tubes better than vertical ones. Boilers should also be adapted for extracting the maximum amount of heat from the fuel, should be easily stoked and cleaned, should burn easily the fuel most readily obtained in the neighbourhood, and should present the minimum obstruction to the upward passage of the water in circulation. The flow pipes should be at the highest part of the boiler, the return pipes at the lowest.

You will have seen from these lectures that in order to construct horticultural buildings, it is necessary to have a knowledge of the details of a great many trades—those of the excavator, the bricklayer, the mason, the joiner, the smith, the engineer, the painter, and the glazier. It is for you to follow up the subject, and bring to bear upon it your horticultural experience. As Lord Brougham once said: "It is very necessary for your success in life that you should know something of everything; but it is quite as necessary that you should know everything of something."

SIR RUPERT KETTLE ON ART.

LAST week the annual distribution of prizes to the successful students of the Dudley School of Art took place. Sir Rupert Kettle, who

presided, said he noticed among the works of art very little effort to realise art in connection with the useful trades of the district. At every school of art he went to be had to say, "Why don't you attempt something to show art in connection with your manufactures? Why don't I see in Kidderminster more of carpets, in Stourbridge of glass, and in Dudley of the staple trades of so great a district?" He found and believed that one of the reasons for so small a Government grant was that the teaching of art was not devoted to the improvement of local industries. He appreciated fine art as well as anyone; but he felt, on public grounds, that the pupils must not look upon that building as merely a drawing school; they ought to look upon it as a school of applied art. In a district like that nothing would be so useful as to pay special attention to mechanical drawing. Hundreds and hundreds of pounds were yearly spent in Lord Dudley's offices in making models for the erection of machinery and for repairs, and yet most of that ought to be done in the office by means of drawings—drawings so well done and so easily understood that draughtsman and workman could fit up the machinery as easily as from models. He did not deprecate freehand drawing; in fact, he loved it, and looked upon it as a second gift of speech, for by a sketch a man might teach another in a few lines what he never could explain. But whilst fine arts and freehand drawing were good, utility ought in manufacturing districts never to be neglected, but encouraged. Sir Rupert Kettle then instanced Doulton's sanitary pipes and Doulton's beautiful and expensive ware as an instance of the value of art when applied to the commonest of materials. Dudley was a large ironmaking district, and they might, by well and judiciously applying art to their manufacture, create a large and a profitable market. Sir Rupert instanced wrought-iron work as an example of what he meant. He had a wretched-looking gas-pendant in front of him—and he would suggest, as a beginning, that any rich man in the room should give a prize for a good chandelier for that room. In conclusion, he asked his audience to take his remarks in a thoroughly practical spirit, and then he believed good results would follow.

TERRA-COTTA AND FAIENCE AS MATERIALS FOR ARCHITECTURAL AND DECORATIVE APPLICATION.*

(WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.)

THE Italian term "terra-cotta," by which a certain class of burnt clay or earth is technically known, at once points to the source from whence it derives its present characteristic features as an architectural material. In such relationship its general use dates from the period of the Italian Renaissance; but historically it was known and used in much earlier times.

In fact it may be said to be prehistoric in its origin, for in many forms it is one of the few links, and in some cases almost our only link, with nations of the most remote antiquity. Both in the form of bricks and more elaborate constructive and decorative forms, it was evidently largely used by the earliest builders known to us who can lay claim to architectural skill.

The remains, fragmentary and otherwise, of both Nineveh and Babylon as revealed by the researches of Layard, Rawlinson, and Porter, clearly reveal its application, and afford not a few specimens of historical, antiquarian, and also of architectural significance. Whether in fact the remains of the very earliest builders of whom we have record can or cannot be absolutely identified, we are nevertheless, in the use of terra-cotta, merely following in their wake, for we read of the men of the East, when migrating westward, that, "coming to the land of Shinar they dwell there, and said one to another, let us make bricks and burn them thoroughly, and they had brick for stone." It is not my purpose, however, this evening to touch upon the historical aspect of the subject, although it might well deserve, and would certainly repay attentive consideration.

In incidentally alluding to the early authentic use of terra-cotta, I merely wish to remark that as an architectural material we have at least some ancient historical and not a few fragmentary

* Paper read before the Leeds Architectural Association on Nov. 24th, by Mr. JAMES HOLROYD.

testimonies to its value, and in considering its modern developments and uses it is not without significance to remember that we are not concerned with something new, but rather with the oldest composite and manufactured architectural material to which we have either historical or fragmentary reference.

That the burnt brick of the ancients is identical in material with the terra-cotta of to-day may seem at first a somewhat bold assertion, yet it is probable that it had a very close similarity to many varieties of so-called terra-cotta.

Burnt brick and terra-cotta are, as regards the nature of the material, synonymous terms. The former may be, and sometimes is, the coarser and rougher form, but not necessarily so nor always by any means. Technically we apply the term brick to forms of certain, or rather uncertain, dimensions and shape within recognised limits as to size—the maximum limit of size being generally that capable of being handled by one hand in the process of building; whilst the term terra-cotta is technically understood to refer to blocks exceeding this maximum, in form more resembling blocks of masonry, moulded in its plastic condition into the required shape and size, and applied architecturally on more or less the same principles of construction as are recognised for the use of stone blocks. This definition may be said to be of general application, but it may be remarked that since the introduction of machinery in making bricks a decided difference of process in the preparation of the raw material tends considerably to widen the distinction between terra-cotta and many classes of bricks. The manufacture of terra-cotta is essentially a plastic process. The manufacture of bricks is not now essentially or necessarily so, for in many districts the raw material is now treated in what is called the semi-plastic or the dry form, and worked into the required shape by mere force of compression, without any of the preparatory plastic treatment, which gives to terra-cotta one of its principal qualifications as an architectural and artistic material. Although it is unquestionable that with certain shales and clays the dry or semi-plastic process of brick-making is capable of producing, and with suitable treatment does produce, bricks of excellent quality and hardness for building purposes at a very low rate of cost, yet, I think, it will not be seriously contested, even by those interested in their production, that, apart from the question of cost, they are entitled to rank with a suitable clay skilfully treated as a plastic material and made into brick or terra-cotta, with due regard to the necessary qualities of a first-class building material. In our consideration of terra-cotta as a material for architectural and decorative use within the limits at our disposal, I think I shall best serve your purpose by describing the nature and quality of the raw material.

The terra-cotta, the burnt brick of the ancients, was probably made of the rich clayey earth, or surface-clay of the alluvial plains, which, being plastic in its natural condition, was most easily susceptible of treatment with the simple appliances at their command. Varieties of the same alluvial formation are preferred in some districts and countries, not only for the ease with which they are worked in the plastic form, but from their abundance and great accessibilities at a minimum cost.

These surface clays were, however, in many respects, the least desirable of the aluminous deposit available for terra-cotta. They preserve, often, indeed, a high degree of plasticity which is most desirable; but this valuable quality is often neutralised by an absence of strength, which renders them unsuitable for any purposes requiring exactness of form and shape, after exposure to even a low heat in process of burning. As a rule, these surface-clays being rich in alumina, and deficient in silica, are reinforced in process of manufacture by the addition of sand and other silicious materials, and in some districts it would be impossible to treat the clay in any practical way without this or similar combination.

In not a few instances the material thus prepared is, however, only available for bricks burnt at a low heat, either in clamps or ovens, and cannot take higher rank than a country-made common brick or a London stock brick. In other cases, by the addition of large proportions of sand, the tendency to twist and warp in burning is checked, but the product is often rendered very porous, and is deficient in the ring and

hardness characteristic of a well-burnt brick material of a superior quality. The shales of the coal measures are in some instances used as a raw material for the manufacture of terra-cotta, but these also are often deficient in silica, and are also more or less in combination with other carbonaceous and deleterious substances. They require very skilful treatment to produce a terra-cotta of even moderate quality, and are, as a rule, deficient in the clearness of colour characteristic of purer deposits of clay.

The natural clays most favourable to the production of the best terra-cotta are those in which silica and alumina bear a proportion of not less than 60 parts of silica to from 30 to 40 of alumina, with but little more than one or two parts of foreign material, chiefly ferruginous oxide. Such deposits are probably more plentiful than they are known to be, but the most important at present available are confined to limited areas, and are not numerous. They are of two or three varieties—viz., the banks or pockets of red marls characteristic of some of the Midlands, Staffordshire, some parts of Cheshire, some parts of North Wales, some parts of Devonshire, with here and there banks of marl similar in formation but with the colouring oxides more or less absent. These banks or beds are sometimes of considerable thickness, and present several varieties of clay. The thickest I know is in North Wales, and probably some hundreds of feet in total depth; it is a remarkably fine bed of red marl. 2nd. Certain anhydrous strata of the coal measures, commonly known as fire-clays, a material composed of silica in varying proportions, from 60 up to 70 parts in the 100, and the rest of alumina, with but small admixture of foreign organic matter. These strata exist more or less throughout the entire area of the coal measures. But I think I shall not be guilty of undue partiality in stating what I believe is generally admitted by those best qualified to judge, that one of the purest strata of this clay hitherto worked in this country, is in the Leeds district, and underlies the large area of what is known as the Low Moor or better bed-coal. It lies at an average depth of (say) 60 yards below the surface, and is of an average thickness of about 3ft. Having a considerable depth of cover, it is very hard and close in texture, and is got only by mining operations by the same methods as coal. An analysis of it indicates great refractile power, with almost perfect freedom from foreign matter or organic impurity. It is unquestionably a most excellent base, in connection with other material, for the production of terra-cotta in any form, from the simplest to the most elaborate, inasmuch as it secures—1, hardness and exactness of form when burnt; 2, solidity under pressure; 3, clearness of colour. The clays of Dorsetshire have also been largely used for terra-cotta, and they are for the most part an excellent clean and plastic material, but they are too deficient in silica to be used without considerable admixture. Although when in suitable combination they make excellent stoneware, and are invaluable to the potter, they are less desirable for architectural work. It will be inferred from what I have already stated that the question of suitable raw material for the production of first-class terra-cotta is by no means simple, and in order to solve the matter satisfactorily, some manufacturers make from the clays of various districts what they consider to be the most suitable body. The London manufacturers, for instance, as well as some others, are compelled to rely entirely on clays from localities at a more or less considerable distance from the place of manufacture. Although by judicious mixing it is no doubt possible to produce a thoroughly good and sound body, yet when the finer and more important proportions of the raw material are imported from considerable distances, often at a considerable expense, there is some danger (in these days of excessive competition) of the product suffering by a too sparing use of the most desirable constituents. I have incidentally alluded to the question of colour; this is, however, a most important point in determining the value of a terra-cotta material for architectural purposes. The principal colouring matter is oxide of iron, present in one form or another in all genuine clays; but these oxides are very various in their quality and condition, and produce remarkably varying results under the action of fire. Some clay will develop

by heat a rich deep red colour, others a warm buff, and these again vary considerably according to the mode in which the heat is applied, or according to the amount of atmospheric oxygen admitted during the process of burning. The colour qualification of each bed of clay can practically be determined only by experience, for although chemical analysis may indicate the actual quantity of iron oxide present, its effect is a matter of direct experiment. In some cases it is necessary to support the colouring properties of the clay by additional oxide; in other cases the oxide is present in too abundant degree, and has to be neutralised. The degree or tone of colour most desirable for architectural purposes ranges from a warm buff to a deep red, and by the aid of recent improvements in manufacture, aided by improved chemical knowledge of a technical character, it is now possible with a good material to produce almost any required tone and any required colour. In the production of these results with any accuracy, the quality of the fuel used is an important element. A variation in the sort of fuel used often produces very perplexing results, and unless its nature is understood, may defeat the greatest care in other processes. A sulphureous coal is one of the greatest drawbacks to purity of colour, and often furnishes one of the constituents for chemical combination with some of the salts evaporated by the clay, and with them forms several varieties of sulphates, often known as "scum," which more or less disfigure the surface of the bricks or terra-cotta. Possibly I may have said enough on the question of raw material to make clear some of the salient points connected with it, and without further enlarging I will pass on to the process of manufacture.

It will at once be understood that the processes of manufacture are only next in importance to the nature and character of the raw material. In some cases, the very simple and elementary processes of preparation are all that are necessary to secure such results as are possible with the material, whilst in other cases a strong and costly plant is necessary to reduce the raw material under control, and produce from it satisfactory results. With the plastic and slender clays to which I have alluded but little more is necessary, if they are clean and free from grit, than thorough working in a pug-mill—a machine composed of knives revolving in a cylinder—the effect of which is to work up the material into a homogeneous mass of the requisite degree of plasticity. In some cases, however, the clay or loam is full of stones, hard grit, which must either be crushed between heavy rollers or washed out, and both these processes are more or less in use. The hard and strong marls and fireclays, however, require more thorough treatment; in many cases it is desirable to reduce them to the condition of a fine powder as a preliminary process. In all clays thorough weathering or exposure to the oxidising influences of the atmosphere is most desirable, and complete plasticity of the homogeneous quality of the clay depends largely on the thoroughness with which this is applied. Unweathered clay is much more likely to twist and warp in drying and burning, than is the case with clay imperfectly and hastily prepared.

Of late years very powerful machinery has been adapted to all the preliminary processes of preparation, by which both time and labour are saved, and certainty of result secured; after being reduced to a plastic condition by these means, the clay is all the better for remaining in a mass for a lengthened period, if suitably protected from incrustation. There are several methods of moulding terra-cotta, and some manufacturers have adopted machinery to some portion of this work; but the only really satisfactory method, although not the cheapest in all cases, is to press it into plaster moulds accurately made from plaster models.

The making of the model is one of the niceties of the terra-cotta manufacture. Unless made to shrinkage rule in the first instance, the design or working drawing of the architect has first to be enlarged, the requisite size to provide for the ascertained shrinkage of the clay in drying and burning. In all the first-class terra-cotta works, this shrinkage can be determined to a very great nicety, and it is most important that it should be so if the various blocks are to work together with accuracy. The most thorough method is to prepare a plaster model exactly representing the

required block, plus the shrinkage allowance; and if this is skilfully done, and a mould taken from it in the way best adapted to moulding the clay, and afterwards withdrawing the mould, accuracy of result is reduced almost to a certainty. It cannot be denied, however, that there is in this operation much room for bungling and equal scope for the exercise of true architectural skill and practical knowledge and experience. Inaccurate or badly-made models and moulds are apt to twist the clay, and are by no means unknown, and hence often follow bad joints, irregular lines, twisted blocks, and general anathemas, only to be avoided by great care and practical skill in the department in which good, careful, and experienced workmen are not too plentiful. When decorative or enriched modelling is required, there is further scope for intelligent and trained skill; many enrichments have been murdered in the modelling, and the most graceful designs converted into hard and lifeless monstrosities from a lack of artistic perception on the part of the modellers. Having personally devoted considerable attention to this subject, I may, perhaps, be permitted in passing to express the opinion that, although the English sculptor in stone can possibly hold his own with the world, yet I have not yet found an English modeler in clay who can hold his own with the Continental modellers of similar calibre trained in the Italian and French methods of manipulation, either in respect to the speed, quality, or spirit of his work. Possibly now that terra-cotta is assuming greater architectural importance in this country, this position may not be of long continuance; but the great requisite is that trained artistic perception should more intelligently guide manipulative skill. After the clay is moulded or modelled, it has to then dry very gradually, for hurry, haste, and push are fatal to true work in terra-cotta. Ample floor or still-room is necessary, of a suitable temperature—and considerable attention is often necessary to regulate judiciously the process of drying. When sufficiently dry—and clays differ as to this condition—the final and possibly most critical process of burning follows. This process is variously performed, according to the quality and nature of the clay, and according to the standard of excellence in colour, exsiccation, and durability sought to be obtained. Some terra-cotta will not bear more than a good red heat, whilst some require a degree of heat sufficient to melt iron, or even steel.

(To be continued.)

TERRA-COTTA LUMBER.

A RECENT American invention is that of the manufacture of lumber from fireclay, patented by Mr. C. C. Gilman, of Eldore, Iowa.

The composition consists of kaolin clay, free from grit, one part; resinous sawdust, from one to three parts, as porosity may be required; water sufficient to thoroughly incorporate the above, by the aid of machinery, into a plastic mass.

Removed from the grinding tubs, where it has been ground, the spongy product is forced by plungers driven by steam through iron or steel cylinders to express the superfluous moisture therefrom, and issues forth in the shape of long blocks or logs, of length, form, and size best fitted for handling, usually eight to twelve inches in thickness and four to six feet in length. When sufficiently dry to render handling safe, these logs are moved into kilns or clamps calculated for the purpose. After the steam and vapours are driven out by a slow, steadily increasing fire, the temperature is rapidly raised to nearly a white heat, which not only consumes the sawdust, but brings the clay itself into the first stages of vitrification. On cooling, the logs are removed to the mill and sawed into planks, boards, and dimension-stuff, as lumber from wood is manufactured, and subsequently fashioned in the workshop into such forms and articles as demanded by purchasers. This material, being free from grit and tough in texture, can be cut, sawed, bored, planed, and carved with edged tools, and before or after such treatment can, after slipping and glazing, be submitted to a second firing, with fine results in ornamentation obtained.

Kaolin is the upper stratum of fire or feldspathic clay beds, and owing to the absence of

sand or free silica is unsuited to common pottery uses, as its warpings in drying and firing unfits it for moulding purposes. Mr. Gilman's invention, so he claims, overcomes this trouble, inasmuch as the material is reduced to form with edged tools subsequent to firing.

Terra-cotta lumber, it is claimed, is indestructible by fire, gases, or acids; is a poor conductor of heat, sound, and electricity; and possesses molecular attraction to an extent which allows of plastering without first lathing. Its weight is one-half less than common building brick, and is erected with nails instead of cement or mortar, virtually rendering fire-proofing a work of carpentry instead of masonry as heretofore.

THE BUILDINGS OF THE CHIEF MONASTIC ORDERS IN ENGLAND.*

A DISCOURSE on this subject was given on Tuesday evening, by Mr. J. T. Micklethwaite, F.S.A., before the members of St. Paul's Ecclesiological Society, at the Chapter-house. Mr. J. P. Seddon, F.R.I.B.A., occupied the chair. The address, which was extemporaneous, was illustrated by large ground-plans of the monastic buildings at Westminster, Durham, Christ Church Canterbury, Fountains, and Mount Grace, near Thirsk, all drawn to uniform scale. The author said he proposed to restrict himself to English examples of monastery buildings, and to render this intelligible it would be necessary to sketch the development of the monastic orders. Of the very earliest, or pre-Anglo-Saxon houses in Britain, we had no remains nor any definite descriptions, but sufficient particulars had come down to us to show that they resembled the Oriental monasteries in including no large buildings, but that men lived in little huts, a mode of life which prevailed in Ireland till a much later period. This Celtic plan of semi-isolated life was in existence when Augustine came from Rome and brought with him, and endeavoured to enforce, the Benedictine rule, by which a system of living in common was substituted for the hermit-like life. A long struggle ensued between the two modes of life, but ultimately the Benedictine method prevailed. These houses had a general ground-plan, which was altered to fit the circumstances of site and requirements, but adhered to an arrangement the origin whereof was so remote that it could not be traced, but which the lecturer believed to be derived from the Roman villa of the better class. A drawing made in 820 A.D. of an ideal monastery intended to be built at St. Galle (and possibly carried out, although no traces remain there of such early work), still existed, and the facsimile exhibited by Mr. Micklethwaite showed a general correspondence in plan and arrangement to the typical Benedictine house in its division into cloister, church, and buildings for housing the monks. The earliest actual remains sufficient to indicate the general grouping were those at Westminster Abbey, usually considered to be of Edward the Confessor's time, though as a matter of fact they were a little later, being of the end of the 11th century. We know from records that at that period the abbey buildings were entirely reconstructed, so that there was nothing to show what the earlier Saxon arrangement was, although the probability was that it corresponded with the existing work, but was planned to a smaller scale. By the time of the Norman Conquest the struggle of conventual plans and modes of life was determined, all the older monasteries having conformed to the Benedictine rule. Some time before that there had been at Clugny a reformation of the Benedictine rule, which was gradually relaxing. For about half a century, from 1080 till 1130, there was in this country a fashion to establish Clugniae houses, the first of these being that at Wenlock. The new order followed generally the Benedictine model, but carried the accessories of worship to the utmost point of splendid elaboration—they were indeed the Ritualists of that day. The next reformation of the Benedictine order went to the opposite extreme, and was a Puritan reaction.

* Ground-plans of Westminster, Durham, Christ Church Canterbury, Chester, Worcester, and St. Stephen's, Caen, drawn by the late Rev. Mackenzie E. C. Wileott, B.D., together with a report of his lecture on this subject before the Architectural Association, to which they formed illustrations, were published in the BUILDING NEWS for March 3, 1876.

It was that known as the Cistercian order, and, beginning in a Burgundian convent, became in about 30 years the most popular order in Europe. Its members affected the greatest simplicity in their services, prohibited the use of stained-glass, carving, and pictures; but, like the modern Society of Friends, determined that while no ornaments could be tolerated, every portion of the building and every detail of the services should be of the very best. The consequence of this was that in the Cistercian buildings we found the most careful designing, planning, and construction, the purest details, and excellent workmanship. The first English house was that of Waverley, in Surrey, founded in 1128; this was followed two years afterwards by Rievaulx, and that in 1131 by Fountains, and before long a very large number of houses erected in the purest style of architecture, and rigidly divested of ornament, were rising in many parts of the land, chiefly in the northern counties. The rise of the order was coincident with the introduction of the pointed arch, and it was probably to the general meetings in chapter of the heads of this order that we owed the simultaneous adoption of this feature throughout Europe. Singularly enough, the Cistercians proved very conservative in their tendencies, and adhered to their style of building and modes of life long after the fashions had changed with others. They were not only the great innovators in architecture, but were also the pioneers in manufactures and commerce, especially introducing the iron-smelting into Yorkshire, as well as the woollen trades. The next reforming movement in the Benedictine rule resulted in the founding of the Carthusian order. The new system was begun at La Grande Chartreuse early in the 11th century, but was not known in England till the foundation of a house at Witham, Somerset, in 1176. The movement developed very slowly, and at long intervals some 15 or 17 houses were formed in this country. One of them was the well-known house near Newgate-street, London, of which traces exist in the school, and another, that of Sheen, near Richmond, Surrey. There was never in our history a rush after any order after the establishment of the Cistercians, because the Preaching Friars came in. The former orders, especially the Benedictine and Cingniae, had appealed to the rich and great for support, the friars were of, and worked amongst, the people, and the modern strife between Church and Dissent was paralleled in the more intense jealousies and disputes between monks and friars. The houses of the new orders were very interesting, but showed so many diversities that a whole evening would be needed for their description, and he must now turn back to examine in detail the houses of the several monastic orders, and their points of difference and resemblance. The familiar example of Westminster Abbey was almost a normal Benedictine house, and from its plan he could show all the buildings which made up such a monastery. To this rule the large cruciform church, and the cloister court surrounded by four covered alleys, one side of which flanked the nave (here, at Westminster on the south) were essential features. The cloister was neither a graveyard nor a mere passage, but was the place where the monks actually lived when not on duty in the church, or at meals, or asleep. Over one walk, here, at Westminster, over and beyond the eastern one, on the first floor, was the long narrow building, the dormitory, and beneath it a room provided with a fireplace, the common hall or parlour. From this dormitory a passage on the first-floor level ran westwards, communicating with the triforium of choir or transept, and so affording a covered and high-level access to the church for the performance of matins. At right angles to the dormitory, and parallel with the church, behind the south walk, was another long building, the refectory or frater. This frater, fratre, or fraytray, was often supposed to be a separate building, but the name was simply an Anglicised form of the refectory or dining-room. A serving-door at the south-west end led into the kitchen, which always adjoined the refectory. When in the cloisters the monks sat on the wall next the church, here on the north side, and in later times, as luxury increased, were provided for in little wooden erections; traces of which might yet be distinguished at Westminster. The novices occupied the west walk of the cloister, and Mr. Micklethwaite mentioned that at nearly

every Benedictine house you might find, by a little examination, the nine holes in the stonework where these youths played tit-tat-toe with round stones; he had discovered them at Westminster, Canterbury, and Norwich, and had no doubt it was usual. The chapter-house was always behind the east walk; it should be as at Durham, Canterbury, &c., an oblong building with circular east end, having seats for the monks on the sides, and for the superiors in the rounded portion. At Westminster this feature was abnormal, Henry II. having determined to erect a Chapter-house that should surpass all others, and accordingly built the present well-known octagonal structure communicating by a passage with the east walk. Close by were, at Westminster and in most houses, the stairs which led from the cloister to the dormitory, and by which the monks descended to the undercroft, common room, or calefactorium, beneath their general bedroom, where more relaxation was permitted than in the cloister. Close by was the treasury, which was in reality a muniment room. At Westminster this formed the undercroft of the Chapter-house, and was now known as the Chapel of the Pyx, having taken the functions of the Royal Wardrobe room, now destroyed. The washing of feet was a great institution in a monastery, the monks having to perform that office for each other weekly, and on Maundy Thursday to wash the feet of some poor man; on this occasion the abbot did the same for 13 poor outsiders, as a proof of humility. The place for the general footwashing was the south walk, that for the abbot being in the east walk. At the south-east angle was a little room, the barbary, for shaving the head and beard. In later times, when the monks got fewer (for at the time of the Dissolution, the system, it would seem not to be generally understood, was falling so much into disuse that the monasteries were almost uninhabited), the monks felt that the great frater was too large and uncomfortable for dining in, and so screened off a small portion. The Benedictines adopted various refinements, but always adhered to the letter of the rule. Thus, they would on no account eat meat or indulge in luxuries in the general frater, but they considered it permissible to enjoy these in a smaller room, known as the misericord, and by the monks as the "disport" or other slang names. In this little room they took by turns, a week at a time, to dine on meat. At Westminster is the only identified one existing in England, in Ashburnham House, which, if handed over to the King's School, as now unfortunately proposed, would be simply destroyed; it lay to the south of the refectory. In a line with the west front of the abbey church, and extending far to the south and west, was the cellarium or cellarer's department. The cellarer was a most important officer, having the management of all the secular affairs of the convent, and in particular of the showing of hospitality—a marked feature of the monastic institution. There were three classes of guests to be provided for. First were the actual tramps, the paupers, the arrangements for receiving whom by the cellarer, till then very complete, were only recently destroyed in the course of "improvements" at Canterbury. Then there were the middle-class guests, who were received at the expense of the house, in a range of divided buildings, generally, as at Westminster, in a line with the west front of church. The third-class were very eminent personages, who were entertained by the Abbot from his own funds and in his own apartments. At Westminster the site of the Abbot's house was now occupied by the Deanery, and his retiring-room or parlour was the Jerusalem chamber abutting on the west end of the abbey church. On the most private side of the monastery at Westminster, to the east, were the infirmary buildings. These were intended to be an asylum and place of retirement for the aged brethren—their use being reserved for those who had been professed 50 years, and must, therefore, be considerably over 70 years of age; but a few sick folk were admitted, and it was frequently alleged that monks were eager to qualify for admission. The infirmary, as at Canterbury and other houses, was a very long hall divided into aisles by an arcade, with a chapel at one end; in later times, when privacy of life was more valued, the hall and aisles were partitioned off into little cells. The infirmary at Westminster was, contrary to the rule, quite secluded from the general buildings, and had a

little cloister of its own. Beyond the domestic buildings on the cloister side of the church were the garden, which was walled around, and could still be traced at Westminster, and the farm buildings. The mode of drainage was simple and effective. The monastery was usually placed near a stream, from which a portion was diverted to turn the mill-wheel; this running water was carried through the buildings as an open channel, and into its sewage and drainage, and all objectionable matters, passed into the general body of the river. The course of this drain-stream could easily be traced to the south of Westminster Abbey. Turning now to the plan of Durham, Mr. Micklethwaite showed how the peculiar site, with the west front of the cathedral church overhanging a bold river-side cliff involved a recasting of the normal plan. Close examination of the buildings would show that the Durham monks attempted to carry out the usual scheme; but it was found too inconvenient, and so the buildings were rearranged so to suit an approach from the west instead of the east. The cloister and chapter-house occupied their right relative positions to each other and the great church; but the infirmary was removed to the west side of cloisters as the most retired position. The prior's house (there being no abbot, as the bishop was the head) was at the east end, but the guest-house and its appurtenances were to the west and south. The position of the house at Worcester, where the west front overlooked the Severn, similarly accounted for the rearrangement to be seen there, where the dormitory and common room were to the west of the cloister, which again was on south side of church; the refectory parallel with south walk, as usual; and the guest hall, &c., to the east of chapter-house and cloister. Except in giving more domesticity and privacy to the infirmary, the changes introduced into Benedictine houses were few and slight during the four centuries they were in use. The buildings of the Cistercian order were marked by extreme plainness. Their common houses were larger than those of the Benedictines, because they did much of their work in them. A peculiarity by which the Cistercian house might always be distinguished was that the frater was placed at right angles, instead of parallel, to the church, and, as a consequence, the kitchen was placed near the cloister, and the scullery at its rear and facing the drainage stream. At Fountains and other monasteries, at a considerable distance from the church and cloister, was a long range of buildings, about which, a few years since, a fierce controversy raged. The late Rev. Mackenzie Walcott contended that it was the *domus conversorum*; but the lecturer and others pointed out that it was too long, and by analogy with Benedictine houses, showed that it was the counterpart of the continuous but divided buildings used as the cellarium or cellarer's offices. By reference to plans of Fountains and Canterbury, Mr. Micklethwaite showed the resemblance, and added that another peculiarity of the Cistercian house was its church. This was nearly always square at the east end, whereas, the Benedictine was sometimes apsidal. Unlike the latter, although cruciform on plan, it was cut up into many different cells by substantial walls, so that the modern idea of a vista could not have been very precious to Gothic men. At Fountains, not only were the aisles thus screened off, but solid stone walls, 10ft. or 11ft. high, and 2ft. to 3ft. thick, were carried across the nave and choir, and other wooden screens were constructed to inclose bays and portions. In many naves also, indeed, of other orders, a pulpitum, now erroneously called the rood-screen, was often to be found near the crossing. It consisted of parallel walls of masonry, on which was erected the organ, and to the east of it was the true rood-screen. The infirmary was like a Benedictine one, but the chapel was smaller, as the sick brothers were expected to come into a private or retro-choir of the ordinary church. The choirmen sat on the south side at Fountains, and the conversi on the north, the latter overlooked by the Abbot's pew on south side of nave. At Fountains, the whole river was taken under the buildings to act as a drain, and streams were carried in stone flues wherever wanted. The last order he should describe were the Carthusians. They lived an isolated and solitary life, each shut up in his little cell, inclosed in a common monastery, and only met at church, at the refectory, and very rarely at the chapter-house.

Most of these houses had disappeared, or had been rebuilt on other lines; but at Mount Grace, so much remained unaltered that the Yorkshire Archaeological Association had been able to prepare and publish a ground-plan. The scheme showed a very small church, to which was attached an irregular four-sided court, 250ft. square. The outside of this quad was surrounded by walled-in inclosures, 20 in number. Each consisted of a garden and a dwelling, consisting of three apartments—living-room, bedroom, and store-cupboard, corresponding to modern pantry—on the ground-floor, and in the roof a little attic. In the garden-wall was a little loop, or narrow passage, turning sharply at right angles, so that the monk who brought round the daily allowance of food should not see or be seen by the inmate of the cell. The latter was supplied with sufficient materials to render him self-dependent except for his dinner, each man having issued to him, according to an inventory which the author recently discovered, two complete suits of clothes, a better and a worse, a razor, whetstone and bone, needles, thread, and comb, writing-desk and writing materials, including pens, chalk, two pieces of pumice stone, and two penknives, lead weight, ruler, prick, two horns of ink, and a style, two pots, two tubs, bread-bag, spoons, knife, basin, water-cup, torch, flint and steel, axe, and firing wood. The use of the attic was unknown even to the modern Carthusians, although they reproduced it in new monasteries. The church consisted of a truncated nave and transepts, a tower to east of these, and a large choir. At Mount Grace this arrangement of 20 cells was found too small, and as it was impossible to enlarge the scheme, a second nest of cells, five in number, were built round the church. In conclusion, the author graphically retold, with the aid of a ground-plan, the story of the murder of Thomas Beckett at Canterbury.

The Chairman expressed his concurrence in the lecturer's views as to the real use of Mr. Edmund Sharpe's "*Domus conversorum*," which he held, at the time of the controversy, was much too large for such a purpose, whereas its utility as a place of reception for the cellarer's guests was obvious. A vote of thanks was accorded to the lecturer.

BOOKS RECEIVED.

Simple Hydraulic Formulae, by T. W. STONE (London: E. and F. N. Spon), is a useful collection of hydraulic formulae applicable to nearly all cases to be met with in the actual practice of the hydraulic engineer. Some of the computations are quite original, and those which are selected have been chosen with care and discretion. — *Economy*, by JAMES PLATT (London: Simpkin, Marshall and Co.), is another interesting book by the author of "*Business*," "*Morality*," "*Money*," and "*Life*." We have read the introductory chapter with great interest. We hope Mr. Platt is wrong in the conclusions he has arrived at in the first part—we are sure he is right in all the rest; and, right or wrong, he invariably writes with a fairness and force that compel thought and eschew disarming prejudice. — *Toys and Toymaking*, by JAMES LUKIN, B.A. (London: Bazaar Office) is the second part of a capital boys' book. It deals especially with clockwork, steam, and electrical toys. — *The Whole Art of Marbling*, by C. W. WOOLNOUTH (London: Geo. Bell and Sons) is a new edition of a work addressed especially to bookbinders, but which will be found useful by decorators as well. Numerous coloured examples are given, and the directions are comprehensive, and easy to follow. — *The British Almanac for 1882* (London: The Stationers' Company) is as good as its predecessors. — *The City Diary for 1882* (London: W. H. and L. Collingridge) has reached its nineteenth annual issue. — *Cities of the World* (London: Cassell, Petter, and Galpin) is the first part of a well produced interesting new publication. — *The Steadfast Aim* (same publishers) is the Christmas number of the *Quiver*, and, as usual, shares all the characteristics of that popular magazine.

Casual wards are about to be built at Market Rasen, for the Caistor board of guardians. The architect is Mr. P. Bellamy, of Lincoln.

ILLUSTRATIONS.

DETAILS OF NEW CHURCH OF THE ORATORY, SOUTH KENSINGTON.—MUNICIPAL BUILDINGS AND NEW MARKET EXTENSION, CHESTER.—BITS FROM CANTERBURY CATHEDRAL.—HOUSES AT LEICESTER.—DOMESTIC WINDOWS IN TERRA-COTTA.

OUR LITHOGRAPHIC ILLUSTRATIONS.

THE ORATORY, BROMPTON.

AMONG our illustrations this week, we give a detail drawing of the cupola for this new church, which is being rapidly pushed forward, so much so that the pendentives of the dome are well advanced, and the centring of the large arches are engaging the attention of the carpenters. This cupola is particularly conspicuous by the absence of the drum (with which such structures are usually accompanied for the purpose of giving additional elevation and greater dignity to the exterior), and although this building suffers in this respect, yet seen from the inside of the church, its medium height may prove an advantage. Its line of springing is about 100ft. above the floor, and it is 51ft. in inside diameter, which is similar to that of the Gesu, S. Andrea della Valle, and the Oratory, at Rome. It may here be not without interest to mention that the cupola of the Roman Oratory is also without a drum, the vault springing from within a few feet of the circular cornice. The four pendentives are carried up in brick in level oversailing courses up to the height of 14ft., and from that to where it meets the circular architrave with radiating joints, the upper angle or feather-edge being formed in Portland stone well doweled together; the vertical portion of the wall from this point will have a slight batter towards the inside until it reaches the thickness of 3ft. 9in., upon which there will be a ring in brick and Portland cement to the height of 12ft., constructed in small portions at a time in well-slaked cement; the upper surface of this ring will represent a thickness of over 7ft., the inner portion forming the skewback for the concrete vault. The ring of the eye at the top will be executed in large blocks of Portland stone, upon which the lantern will be erected. The whole of the concrete vault will be protected with an outer shell of woodwork, covered, at least, for the present, with 16oz. Vieille Montagne zinc; this intermediate space will inclose a staircase, giving access to the lantern. The vertical portion, or dado, will have at the back a series of recesses for the purpose of easing the weight on the pendentives, and the eight angles which fall on the haunches of the main arches will be considerably strengthened with additional brickwork and buttresses. The estimated cost of this portion of the church is about £10,000, but only a part is being carried out at present, and is being done by Mr. Geo. Shaw, of Westminster, under the direction of Mr. Herbert A. Gribble.

THE CHESTER TOWN-HALL AND MARKET EXTENSION.

The Town Hall, as erected, was designed by Mr. W. H. Lynn, and was carried out under his superintendence. The design was adopted by

the Corporation of Chester on the advice of the late Sir M. Digby Wyatt, who had been called in to advise on the merits of the designs submitted in competition for the work in 1864. The new buildings were inaugurated by the Prince of Wales, in 1869. The space between the covered market and the site of the Town Hall was occupied by tavern premises, which, owing to rights of light which they enjoyed, prevented the completion of the return of the new building towards the market. This had to be sloped inwards from about two-thirds of its depth as a temporary expedient. The Corporation having acquired this property, are now extending the market accommodation up to the Town Hall boundary, with a front towards Northgate-street, in keeping with the style of the Town Hall. This, which is shown in our view of the buildings, is being carried out from Mr. Lynn's designs also. The return of the south end of the Town Hall is drawn complete—a condition which, it is to be hoped, it will be left in before the opportunity for accomplishing it simultaneously with the market work is allowed to pass. The extension of the market is being carried out by Mr. W. Edge Samuels, of Wrexham, contractor, under the superintendence of Mr. J. Matthew Jones, the City surveyor of Chester, who has prepared the drawings of all the work now being done, with the exception of the new front designed by Mr. Lynn.

BITS FROM CANTERBURY CATHEDRAL.

CANTERBURY CATHEDRAL and its precincts afford a vast field for study to the architectural student, being one of the best examples of the gradual growth and development of an English Cathedral, without destroying the harmony of the whole. The diminution in width of the choir at its eastern end is full of suggestions for interior effect, without destroying the grandeur of the exterior, if artistically treated. Another peculiarity is the approach of the choir by two flights of steps from the nave, and the north and south transepts, being the same level as the nave, are descended to from the first flight of steps to choir; the crypt, which is under the choir and its aisles, is entered by steps from the east end of north transept. The view from the north-west of cloisters, with the magnificent central tower, is very striking, its buttressed pinnacles giving play of light and shade, notwithstanding its want of graduation in bulk. It was begun by Archbishop Morton and completed by Prior Goldstone, and is 235ft. in height. The north and south transepts were rebuilt in 1379 by Archbishop Sudbury. The north transept, called the Martyrdom, the scene of the murder of Thomas à Becket in 1171; a stone screen separating that spot was taken down in 1734. There is some of the Norman masonry remaining in the north-west corner of the north transept. The nave, begun by Archbishop Sudbury, and finished by Archbishop Courtney and Arundel in 1410, has little of historical associations. As will be seen in the accompanying sketch, the aisle-windows are the same in design as the west window in transept. The Chapter-house or Sermon-house, approached from the cloisters, was rebuilt by Prior Chillenden, about 1400, assisted by Archbishops Arundel and Courtney. It is 92ft. long, 27ft. broad, and 54ft. high, and is remarkable for its curb or mansard roof, covered with sheet-iron; the effect of the interior is better than that of the exterior, having no ties, and being divided into panels by moulded ribs. The whole was originally decorated with esuteheons, &c., which have partly been restored. The south side of cloisters, leading from palace to north transept, was rebuilt by Archbishop Courtney, and the remaining three sides by Prior Chillenden, and were afterwards glazed. On the north side was the refectory, which, with the library adjoining the Chapter-house, completes the interesting quadrangle.—T. H. CURREY.

HOUSES AT LEICESTER.

THE houses at Leicester of which we give a view this week are placed in the best residential part of the town, near to Victoria Park. They are four in number, and each contains three sitting-rooms, good kitchen premises, abundant bedrooms, and all conveniences. They are built of good red local bricks, and roofed with Broseley tiles. The timber-work is red deal, and portions of the plaster filling are enriched with carving. Messrs. T. and H. Herbert, builders, of Leicester, are carrying out the work

under the superintendence of Messrs. Goddard and Paget, MM.R.I.B.A.

DOMESTIC WINDOWS IN TERRA-COTTA AND FAIENCE.

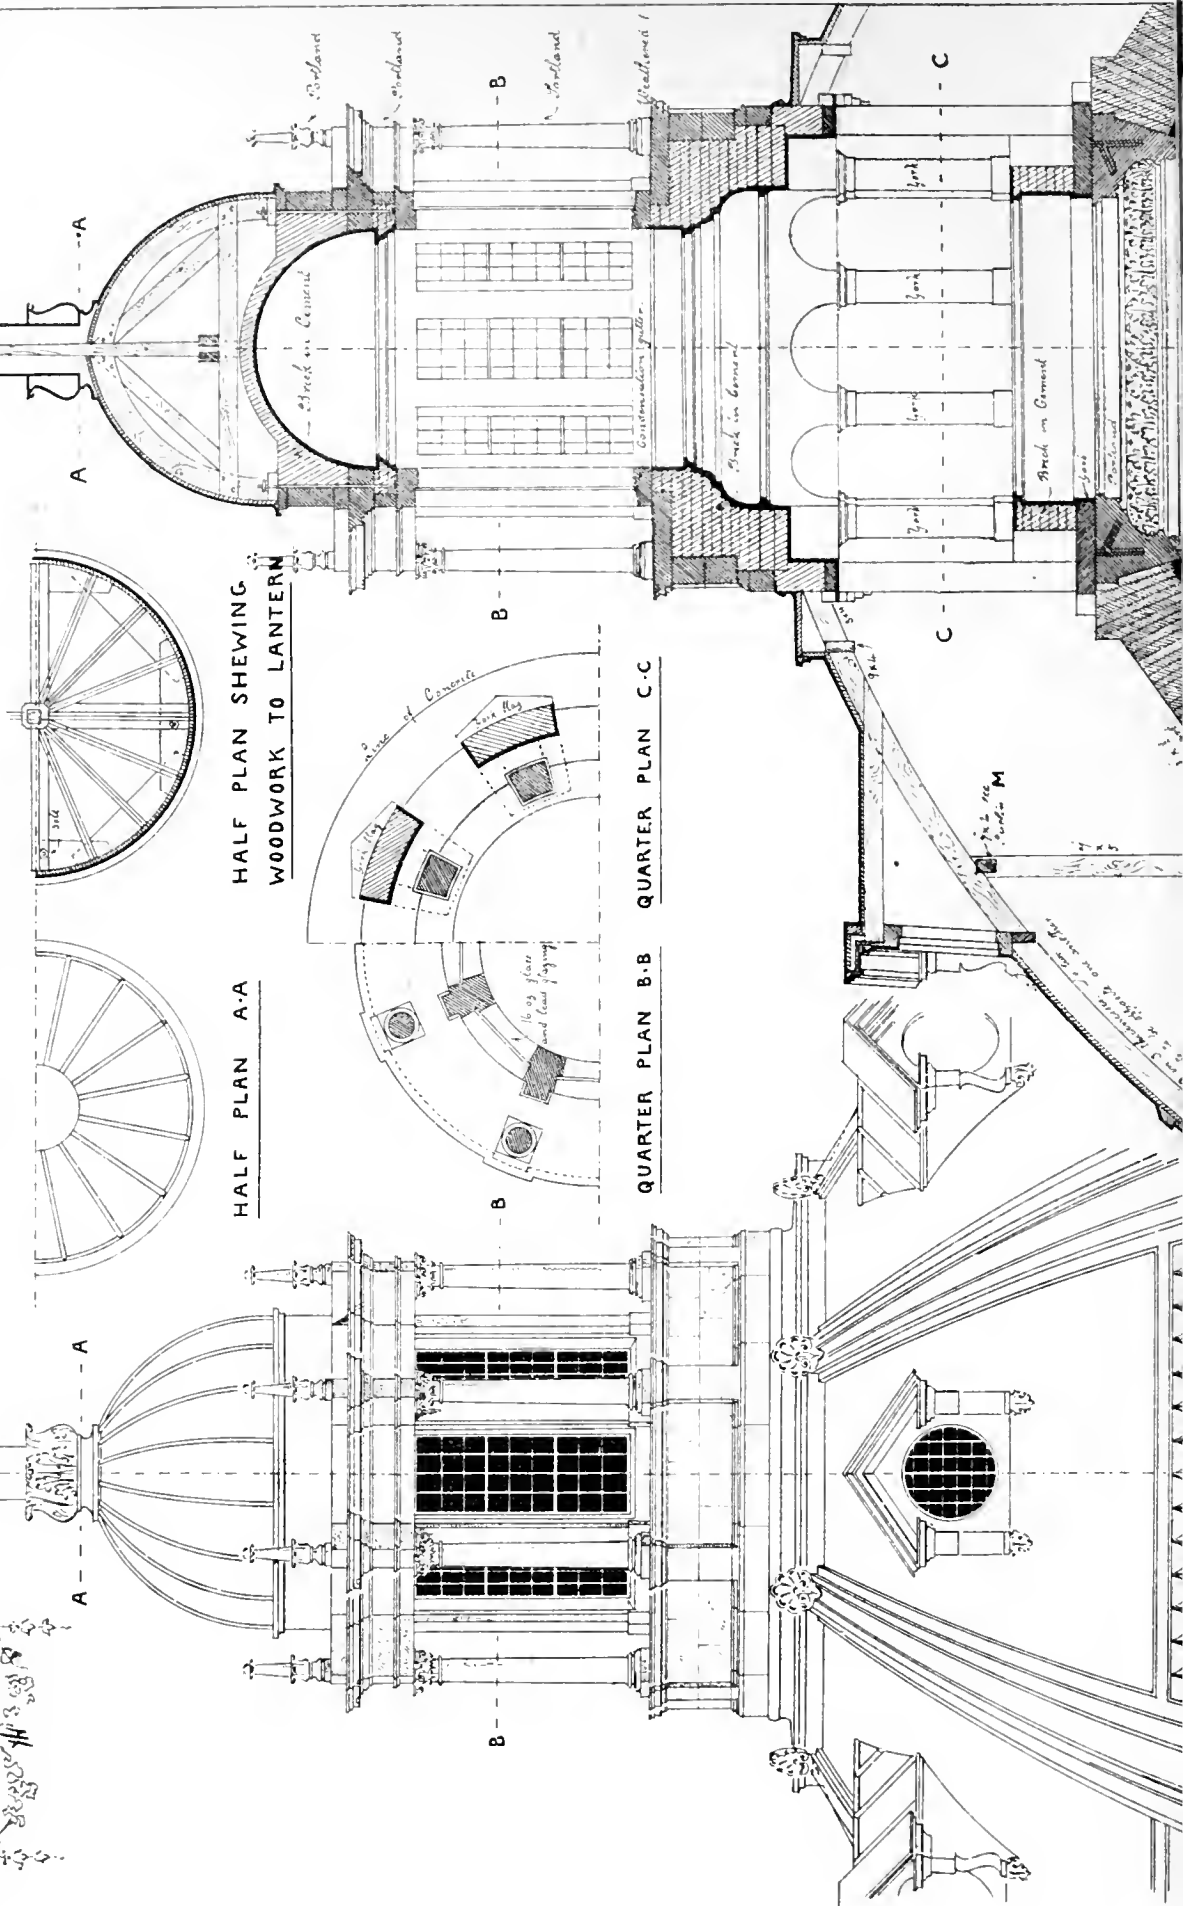

THESE examples illustrate a lecture delivered this week at Leeds, which is reported elsewhere in this number.

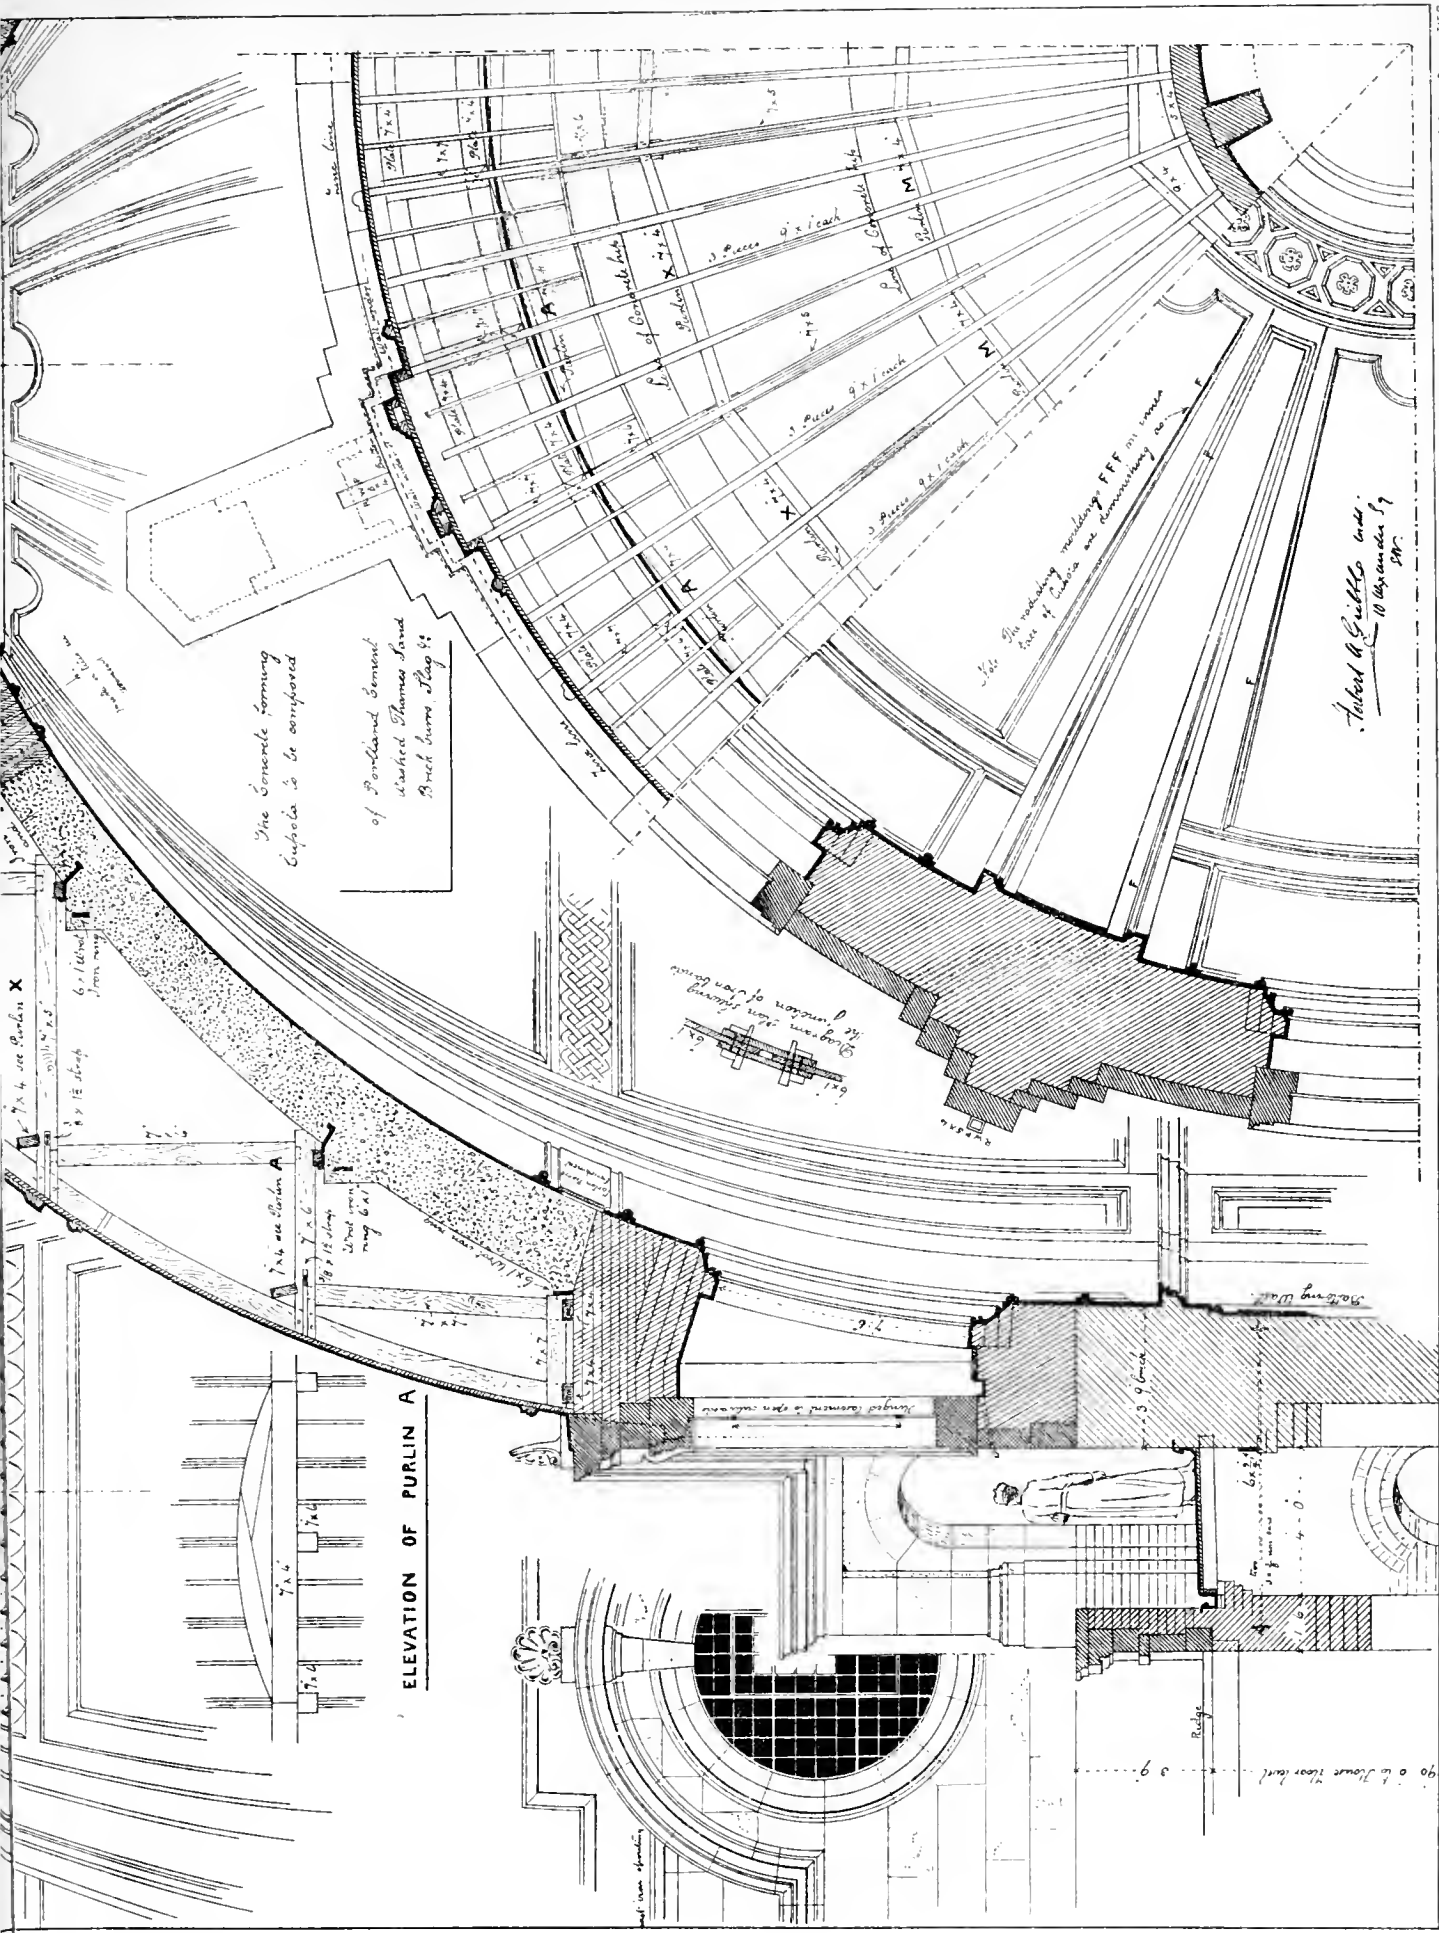

THE NEW PATENT "ELECTRIC" PAINT REMOVER.

A VALUABLE addition to the resources of the painter's art has been patented by Messrs. Rendle Brothers, of 3, Westminster Chambers. The "Electric Paint Remover" is the name given to a chemically prepared compound for removing old paint, varnish, tar, rust, grease, &c., from wood, metal, stone, and fabrics of all kinds. Last Monday we were invited by Messrs. Rendle to see some experiments made with this preparation upon various specimens of painted wood and metal. These were all old samples, well painted with several coats of good oil colour. The compound, which is of a cream-like consistence, quite white, is spread over the painted surface, and after being left on a few minutes, is wiped off. The inventor made some remarks upon the chemical properties of different sorts of paint "removers" known to the trade. These were generally compounded of alkalies, soda, potash mixed with lime, which latter was known to have a dehydrating action on the fibre of the wood. The result of the use of these preparations was that only the first film of paint was removed, the body of paint being imperfectly acted upon. While some of these preparations remove paint of ordinary work, for paintwork of several coats they are quite inoperative. The new "electric" paint remover is chemically prepared according to a scientific formula, in which potash and soda are the principal ingredients, but in which there is not a trace of lime present. Its action upon the body of the paint is thorough and complete, a saponification is set up which continues, the soda is liberated, and fresh soap formed, and this process goes on; the alkali being liberated as it is wanted, till the whole of the paint is removed. The specimen we saw acted upon only remained about a quarter of an hour subjected to the action of this caustic preparation, and the compound being wiped off, every trace of paint was found cleanly removed, and the wood exposed appeared as if it had been planed. Nothing could be a more satisfactory test of the destructive action set up by this material. Directly the compound touches, saponification is set up. The action of this preparation seems to be twofold; there is first the destructive action of the applied alkali, always caustic, and next a continued sponge-like action going on—in other words, a constant and perfect causticity is maintained. The result of the preparation on metal was equally convincing. A gas-meter which had been thoroughly coated was exposed to the compound for about twenty minutes, after which the japan was removed and the bright metal exposed. The other forms of this preparation we saw were of a weaker character and nearer soap in their composition. They are intended to remove dirt, and their action is just the reverse of the compound already described. The preparations are liquid and are soluble in water, and their cleansing power upon cloth of an unmistakably greasy and dirty character was almost magical. For delicate carvings and fabrics of all kinds these solutions are admirably adapted, and we think their use by restorers, decorators, and others will be highly esteemed. The modification of the solution for cleaning cloth is well adapted for restoring the linings of railway-carriages and stuff seats of all descriptions. No scraping or erasing is necessary. There is nothing injurious, we are told, in the preparation which can attack or injure metals or cloths, they all produce a minimum action on brushes, which is a consideration, and, what is very important, colour is not taken out by the use of these solutions. The price is less than that of other preparations. The "paint remover" can be easily applied by being spread over the painted surface to be removed. It is sold in 5lb. tins at 2s. 6d. each, and the patentees are prepared to give special quotations for large quantities in bulk for railway, gas, and shipping companies, &c.

MR. VAL PRINSEP ON ART.

THE prizes gained by the successful students of the St. Martin's School of Art were distributed last Friday evening, in the School-room, Castle-street, Long-acre. Mr. Val C. Prinsep, A.R.A., who presided, distributed the prizes and then, addressing the students, said great credit was due to them for giving, after the close of their day's work, a few hours to the study of drawing. That study would never be thrown away. The knowledge of drawing would help them in the mechanical arts they were pursuing. The voyage made in the pursuit of art was longer and more difficult than that undertaken by any mariner. They must remember, too, that often the smaller the work of art the greater the labour bestowed upon the picture. To those who were studying art with a view of improving themselves, he should like to point out a way by which they could do so with success. Supposing, for instance, a friend of theirs was anxious to learn a strange language, what advice would they give him? Why, they would recommend him, after acquiring the language, to learn the literature that had been written in it. And so it was with art. They were studying a language. He saw from the determination they had shown that they had a mind to know the meaning of art. For that purpose he advised them to visit the different picture-galleries in London, and when there, to ask themselves what the artist meant to express when he painted the picture. And the same thing applied to sculpture. Beauty was, no doubt, everywhere, and it was one of the great functions of art; but as art was not born in man, but was a matter of education, so also was the idea of beauty. Dealing with the progress made in art, Mr. Prinsep urged upon the students the importance of learning the grammar of art. They might leave out what they liked in art, but what they did put in should be absolutely exact and truthful. He then traced the progress of art since the time of the Greeks, in which days the Church was its great patron; and showed its condition in the seventeenth and eighteenth centuries. It seemed likely, he said, that art would rise again with redoubled success. True art was a mixture of art and nature. Art by itself would not do, neither would nature by itself; the two combined were necessary. He warned them against being led away by enthusiasm and over-estimating the value of a work of art executed by themselves. They were apt to admire things that struck them as original, but which were only eccentric. "Eccentricity was not genius" was a precept he would impress upon them; nay, he would have it written in letters of gold, on the walls of every art-school in England, where the students seemed more influenced by peculiarity than the Frenchman or the German. Lately we had heard much of the "aesthetic." Aestheticism was in possession of the stage and in the mouths of all. Aesthetics might be seen in our streets, clad in sad greens and sickly yellows, with long or unkempt hair and shaky legs. The word came from the Greek, and originally meant "sentiment, or the pleasures derived from the senses." The greatest geniuses had been the simplest men, and it was these great men who might be called aesthetes, professors of the science of the beautiful, expounders of the beauties of nature. Let them, then, be true followers of aestheticism. When such a knowledge of art, such a profusion of the beautiful, got thus spread, Art would prosper and find very much more scope on which to exercise its civilising power. Mr. Luke Fildes, A.R.A., also spoke, and said the secret of success in the work in which they were engaged was to be full of earnestness. The student might not at the time think that he was able to reach the goal that he was seeking, but it was very wonderful how, little by little, success would come.

THE ELEMENTS OF ART.

UNDER this title Mr. Joseph A. Stark delivered on Friday evening the first of a series of lectures on Art, before the members of the Balloon Society at the Royal Aquarium, Westminster. In his introductory remarks the author mentioned that he was a follower of Professor Semper, of Vienna, who in his great work on "Style," had set the claims of art before us in quite a new light. He proposed

that evening to deal with art in its philosophical aspect as a process, and as an aim. He defined art as nature filtered through the complex machinery of human thoughts and hopes; as the reflection of permanent nature seen in the mirror of fleeting man. Art is, he said, the spring of our life, at once man's distinctive attribute and his highest effort—man himself at his highest valuation. But one other power sways the heart with equal force, that of Religion, or in a broader sense, Philosophy. Art and philosophy are the primary necessities and products of human nature—one in essence, but distinct in application. All work which aims at representing the ideal personality and hope of man is an art manifestation. Such are music, poetry, sculpture, painting, and the higher prose literature. Other branches of work are not essentially art manifestations, although they can be raised to that level by the manner of their performance; such are pottery, textile manufactures, carpentry, and stone construction. These lead up to and find their climax in architecture, which is an art only by imparted interest, although it can realise for us the highest degree of material expression. In other words, art may be divided into philosophical and material. The bulk of modern art is mere reproduction—a borrowed and copied, and not an original, art. The inferiority of modern art is one of necessity caused by the accumulation of the past, and the exhausted state of our natural resources. It does not follow that if our great inheritance from the past could be obliterated, we should do better than they did; but our work would be carried on with greater vigour, and would give more satisfaction than was now possible. As an instance, the gratification with which the American citizen, ignorant of Classic art, looked upon the copies in his streets of Greek temples and Gothic cathedrals, was referred to. But the past could not be effaced, and the only thing possible, therefore, was to endeavour to understand its character and charms, and to re-compose the several items into intelligent and consistent re-issues. This was the province of the new philosophical school of Semper, which sought to free art from the fetters of corrupt traditional teaching, and to establish her on the true foundation of our common human nature.

ST. DUNSTAN'S CHURCH.

ST. DUNSTAN'S CHURCH, Fleet-street, has undergone of late thorough repair and decorations, and the church was reopened by the Lord Mayor last Thursday week. The church in plan is an octagon, with eight recesses opening by pointed arches from the central area or ball, and is on this account of more than ordinary interest to the architect, as showing the adaptation of this plan for town churches. St. Dunstan's in the West was designed by the late Mr. John Shaw, an architect of some eminence, and was erected in 1838. It is in the Perpendicular Gothic style, and has a western tower and octagon lantern which from its resemblance to the one at Boston, in Lincolnshire, is rather interesting. The period of its erection was too early in the history of the Gothic revival to expect any very thorough acquaintance with Gothic detail, and the restorer had of course this circumstance to take into consideration. The principal alterations that have been made consist of the removal of the two running galleries on the southern apsidal recesses, and the introduction of two windows with Perpendicular tracery. One of these in the baptistery has been filled in by the memorial window, designed in memory of the late rector of the parish, the Rev. Edward Auriol, who had officiated in that capacity for 38 years. The design of the window in question was submitted in competition and was described by us. The subject is "Christ Blessing Little Children," and the design and execution has been entrusted to Messrs. Taylor and Sons, of Berners-street. The other window, we hear, is to be filled in at the expense of the Cordwainers' Company, in memory of John Fysher, and will represent in its chief lights the subject of the "Good Samaritan." These semi octagonal recesses have been also paved with mosaic pavements in effective squares by Messrs. Simpson, of St. Martin's-lane. The other alterations and additions made are raising the choir stalls in one of the apsidal recesses on the west side of chancel, repairs to the tower, and iron ladders to the lantern, and a lighting-conductor.

But the chief feature in the church are the decorations. These have been carried out by Messrs. Campbell and Smith in a satisfactory manner, chiefly in distemper. The walls and roofs were before of a stone colour; these have been cleaned and repa red, and a high dado of a pleasing neutral green, with a border of white flowers on a warm ground, now surrounds the walls and recesses, above which is a lighter shade of neutral green laid in courses or blocks of a conventional kind, and relieved by small powdering or stars in alternate courses. This treatment is carried up to the level of the springing of arches, above which the spaces are relieved by a diaper on a light cream ground. The ceilings of the eight recesses, four of which at the angles are semi-octagonal, are all relieved by colour, at the springings of pendentives also by blue bands of colour, relieved by four-leaved flowers, and by the ribs being picked out in warm salmon colour. The spandrels of the main arches, carrying the octagon clerestory and groined roof, have been decorated with bands of grey green and salmon tints at the springings, and with folial designs in light greyish-green round the quatrefoil piercings. A deep stringcourse surrounds the walls, above which is the clerestory, the wall spaces of which have been diapered, and the octagon-groined ceiling of plaster has been treated in a light and effective manner: the surfaces being lined in courses and the ribs picked out with warm members. The centre pendant from which the gas corona is suspended is also relieved. The chancel has a waggon roof with ribs which has been similarly treated but not emphasised; the old reredos, with the Decalogue and the canopies over, and the panelled wall lining, remaining. The old oak seating has also been left, and the woodwork generally is in excellent condition. The main piers at the angles of octagon, which rise to the main vault, are relieved by the outer shafts being coloured a sage-green, and the side shafts with a salmon tint, the hollows being left cream, relieved by fillets being picked out in the warm salmon colour. The general effect is quiet and unobtrusive, and the scheme of colour appears to have been happily chosen to give surface relief and to keep the architectural lines. The whole of the work has been well carried out by Mr. H. S. Foster, builder, of Whitefriars-street, under the supervision of the architects, Messrs. Fowler and Hill, of Serjeant's-inn.

RUFFORD ABBEY.

THE *World* gives some account of Rufford Abbey, in "the Dukeries"; which is described as alike beautiful in situation, and in the ruddy-grey colour of its decaying sandstone walls. The Abbey was originally the offshoot or colony of Cistercians from Rievaulx, and when dissolved after the seventeenth abbot, the house and land were given by Henry VIII to the Markhams; and on the expiration of their tenancy, to the fourth Earl of Shrewsbury and Waterford, in exchange for some estates in Ireland, and finally went *via* the Talbots, into the Saville family. All that is left of the original Abbey is the enormous crypt. A portion of this, with beautiful pointed arches, is made into a servants' hall, and the remainder serves as a wine and beer-cellar. There seems to be plenty of crypt to spare, and this, it may be added, is very much the effect of the old house. There is plenty of room, not always perhaps where it is wanted, but there is, at least, an old-fashioned amplitude about the house. Rufford is full of relics of historic personages, refectory or hall tables of ancient oak, pikes, guns, jackboots and blackjacks. It is also full of interminable passages, of corridors which seem to have only one end, and of mysterious flights of stairs, leading one into queer nooks and corners, chapel galleries, and haunted chambers. Some of the rooms have been restored during the present century, but the result is not quite so unhappy as might have been expected, and Rufford has not, like many other old houses, been destroyed by successive generations of inhabitants straining to bring it into consonance with their own idea of comfort. Mr. Augustus Saville Lumley, who recently succeeded to the property, on the death of his half-brother, "Mr. Henry Saville," has already seriously considered the necessity of arresting the decay of his beautiful house—a gem when compared with the vulgarity of Clumber,—and

has consulted Mr. Ellis as to a cautious and delicate strengthening of it. Repair is hardly the word, and "restoration" makes one shudder; but there is no fear that Ratford will be roughly handled.

Building Intelligence.

DUNFERMLINE.—The members of Dunfermline Free Abbey Church have resolved to build a new church, and Messrs Douglas, Campbell, and Sellars, Glasgow, have prepared the plans, which show a building in the form of an octagon, with pinnacles at the corners. The style of architecture is Norman. As viewed from a distance, the church will look pyramidal in shape, the total height being about 100ft. The chief elevation will be towards Canmore-street, and the chief entrance is flanked on either side by fluted pilasters with foliated capitals, and surmounted by heavy cornice. Internally the church will measure clear 15ft. across, and round five sides of the octagonal gallery will be erected. The church is expected to accommodate 800 people. A hall is also to be erected with accommodation for over 200. The total cost is expected to be £5,500.

GALASHIELS.—A new church for the parish of Galashiels was opened last week. The estimated cost, including the spire, but exclusive of organ and pulpit, was about £13,000. The style is Early Decorated Gothic. The masonry outside and inside is of finely hewn stone—the outside of red-sandstone, and the inside of coloured grey sandstone, intermixed with red-stone mouldings and other details. There is neither lath nor plaster, the stones being clean chiselled and close set. The spire with the tower is to be 190ft. high, but the tower is only built as yet. A spacious hall is built at the south end, for the use of smaller meetings. Inside, the church is divided into nave, aisle, and transepts. The length of the nave is 83ft.; width across nave and aisle, 58ft.; width across transepts, 82ft.; breadth of transepts, 10ft.; height from floor to wall-plate of nave, 36ft.; height to apex of roof, 62ft. The roofs are of open-timber work, supported on corbelled shafts of red freestone, with capitals and corbels carved against clerestory walls. The architect is Mr. Hay, of Edinburgh.

HULL.—A new Unitarian church at Hull was opened last week. The buildings are designed in Geometric Gothic, freely treated, and are erected externally in white stock bricks, with Ancaster stone tracery, copings, and dressings. There is a spire about 90ft. in height at the north side. In the interior the church is divided into nave and aisles, with clerestory lights above. Sittings are provided for about 300. The accommodation at the rear of the church consists of a large schoolroom on the first floor, with sitting-room for about 300 persons. The designs are by Mr. W. H. Kitching, architect, Coggar Chambers, Hull, while the builders are Messrs G. Jackson and Son, Hull. The total cost of the land and buildings will be about £14,000.

LLANDINABO.—The parish-church of Llandinabo, was reopened by the Bishop of Hereford on Tuesday week, after restoration. It is a very ancient structure, and in the course of the work, on removing the plaster ceiling, an interesting 13th-century truss rafter roof was found in a good state of preservation. The existing registers date back to 1596. The church has been restored from the designs, and under the superintendence of Mr. A. E. Lloyd Osell, A.R.I.B.A., diocesan architect for the archdeaconry of Lullow. A new north aisle and vestry have been erected: the gallery has been done away with. The old external walls have been entirely refaced with new stone, a porch has been added to the south door, and an oak bell-turret, seven feet square, has been erected on the west gable. The old roof-timbers have been exposed to view, and the interesting 16th-century oak chancel screen restored to its original form. The old Jacobean pulpit has been recast and fixed at a lower level, and, instead of the old-fashioned pews, open pitch-pine benches, all free, have been placed in the nave and chancel. The floors are laid with Mr. Godwin's tiles. The whole of the work has been carried out by Mr.

J. Court, builder, of Llanwarne, near Ross, at a cost of £660.

METROPOLITAN BOARD OF WORKS.—At the weekly meeting of this Board, held on Friday last, a report was brought up by the works committee, recommending the enlargement of each of the main sewage outfall reservoirs by 50 per cent., namely, that at Barking, by the addition of five acres, at an estimated cost of £100,000, and Crossness by three acres, at an estimated cost of £60,000. These amounts simply represented the cost of execution, the land being the property of the board, and by the extensions the board would get rid of the necessity for the discharge of sewage, except at ebb-tide. The report was adopted, and the chief engineer, Sir J. W. Bazalgette, was instructed to prepare contract drawings for the work. It was resolved to contribute £21,912, being one half the estimated cost for setting back seven houses on Lugate-hill, and contributions of £2,687, £1,267, £850, and £708, were respectively voted, as moieties of costs for other City improvements in Long-lane, West Hardiog-street, Pudding-lane, and Old Broad-street. Towards the improvements of the bridge over Blackwall Dock entrance, Poplar, £325 was voted. With reference to a memorial from Chelsea, objecting to the carrying of the proposed flood relief sewer down Sloane-street, it was resolved to adhere to the original proposal, the engineer being instructed to carry out the work with as little inconvenience as possible.

PLYMOUTH.—The public school in Cobourg-street has just been extended and enlarged. The head-master, Mr. Jago, prepared the plans and designs, and has acted as architect. A local journal asserts that "the style is nondescript." The school consists of a double bay front, relieved with terra-cotta dressings. Porphyrus stone has been used, with blue nobbing pointed in Portland cement. The ashlar work has been done in Portland stone, and the cornices consist of terra-cotta with Macfarlane's ornamental gutting. The railings have been supplied by Messrs. Smith, of Glasgow; the plumbing has been executed by Messrs. Colling and Hocking, of Plymouth. The cost of the extension is about £2,000, and the contract has been executed by Messrs. A. R. Lethbridge and May. The carving was done by a local man, Mr. David Ross.

RYDE.—During the past two years considerable alterations and improvements have been made in St. Mary's (Roman Catholic) church, Ryde. The church was built in 1844-46. It was designed by Mr. Joseph Hansom. In the year 1863 the church was decorated by Messrs. Hardman, and soon after Bishop Grant consecrated it. In 1879, the whole of the Caen stone, in which the dressings were carved, was found to have perished, portions of it falling occasionally into the street; and it became necessary to replace the Caen stone with Portland stone throughout; advantage was taken of the opportunity thus afforded to alter the character of the window over the high altar and to fill it with a memorial window to the founders. The Bishop of the diocese, and the missionary rector, placed the work in the hands of Mr. Philip M. Westlake. The window represents in a trefoil Our Lady of the Immaculate Heart (to whom the church is dedicated) enthroned, with the Divine Infant, and attended by angels. Mr. Westlake has also designed two other windows, to complete the series in the south aisle, one being the Immaculate Conception, and the other St. Wilfrid, the apostle of the Isle of Wight, both excellent works of art. A member of the congregation has also directed Mr. Westlake to design the Stations of the Cross for the church, and nearly half of these mural paintings carried out under his personal supervision are now in their places. The total cost of these repairs and artistic additions up to this point had been above £2,500, when Father Cahill, in the work of the restoration of the church, determined to perpetuate in the church the memory of the late Bishop by a memorial similar to that of its founders. For this purpose the talents of Mr. Philip Westlake were again called upon, and he has just finished a most successful piece of church decoration. The whole space above the chancel arch has been filled by a painting representing Our Lord in Majesty. Our Lord is seated on a cloud, His right hand raised in blessing, and in His left the orb of the world. Around Him and forming the *resica* of holiness

are the seraphim, below on either side are Our Blessed Lady and St. John Baptist. Underneath are angels censuring, while one leans over the battlements of the walls and holds the shield of Bishop Danell, second Bishop of Southwark. The painting is somewhat in the character of the middle Renaissance period; the principal figures are about eight feet high.

COMPETITIONS.

DUBLIN MUSEUM COMPETITION.—Sixty sets of designs have been sent in for the Dublin Science and Art Museum, and the judges have commenced their work. These are the Lord Mayor, Lord Powerscourt, Mr. Mayers, builder; Mr. J. J. McCurdy, architect; Mr. W. G. Hodson, and two assessors from Kensington. We regret to learn that some uneasiness exists among the competitors with regard to certain points discussed by correspondents on pp. 608 and 611. We trust the result will prove that the Committee of Selection have not overlooked the very necessary qualification for the proper discharge of their duties, pointed out by "Fair Play," on p. 608.

SKEGNESS BATHS COMPETITION.—At a meeting of the directors of The Skegness Swimming, Hot, Cold, and Turkish Baths Company, held on the 22nd November last; it was decided to adopt the design sent in under the motto "Convenience with Economy," the author of which, Mr. James Whitton, of the city of Lincoln, was commissioned to carry out the work. The second premium being awarded to Mr. H. A. Goodall, of Nottingham. Seven designs were sent in. The buildings will be commenced at once. The baths will be supplied with sea-water. The materials to be used are red bricks for all walls, stone being slightly used in the fronts. The swimming baths will have iron roofs covered with galvanised corrugated iron.

WIMBLEDON.—In a limited competition for Congregational Church and Schools, Wimbledon, the design submitted by Mr. W. D. Church, architect, of 12, South-place, Finsbury, was unanimously chosen by the committee.

SCHOOLS OF ART.

BURTON-ON-TRENT.—The annual distribution of prizes and certificates was made by the Mayoress on Friday evening. The report of the Science School showed that 89 per cent. of the students examined passed, earning for the school £55. The financial statement adverted to the fact that the receipts of the schools had been £107 4s., and the expenditure £131 10s. 1d., they were about £10 2s. in debt. The report as to the School of Art referred to the fact that Mr. Simmonds, the late head-master, had obtained the valuable appointment of head-master at the Glasgow School, and had been succeeded by Mr. Whitehead. The results of the year's teaching had been highly satisfactory, two third-grade and ten second-grade prizes had been gained for drawings sent to South Kensington, and ten other second-grade prizes at the examinations, being a total of 20 second-grade prizes, as against 6 in the previous year. The Government grant, £52 1s., was the largest ever obtained by the school.

CHIPS.

The prizes and certificates gained in the science and art schools at Stratford, E., were distributed on Friday evening by Sir Antonio Brady.

Mr. Thomas Hallon, a timber merchant and saw-mill owner at Middlesborough, died on Saturday, aged 75 years. He served his time as a joiner and cabinet-maker in the shop of his father at Shildon, along with the well-known author, William Howitt, and had lived in Middlesborough for 38 years.

A stained-glass window has been placed in St. John's Church, Portmadoc, to the memory of the late Mr. John Breese, F.S.A., a well-known Welsh antiquary and bibliophile.

For some time past, the use of the unusually heavy tower bell at St. Mary's, Keelington, has been discontinued, owing to the threatening condition of the beams, and on Sunday week, while the other bells were being rung for service, the next largest bell fell from its bearings. The firm of Bond and Sons, of the bell foundry at Barford, Oxon, are now rehanging the peal.

"To a practical man with a taste for mechanics, and the humps of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the Joe numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recordable information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Englishman*. Price Two-pence of all newsmen, or post free 2s. 3d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in series advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—F. W. R. and Co.—W. H. S. and Co.—C. P. K. and Co.—J. and Co.—W. H. L.—E. and Co.—S. S. B.—S. U. G. C.

INQUISITIVE. Some of the washes would not show at all; the others would come out a dense black and spoil the drawing.—B. (We do not, if we know it, insert letters which are sent to other journals.)

"BUILDING NEWS" DESIGNING CLUB.

LIST OF SUBJECTS.

1. A small country club, with a billiard-room, reading-room, and drawing room, the latter to be fitted for a stage suitable for private theatricals, one of the other rooms to be used as a green-room. Steward's sitting-room, kitchen, and two bedrooms, with offices, to be provided. Plans, elevation, and section to an eighth of an inch scale, with sketch. The frontage to be 60 ft.
2. Bookcase and arm-chair, suitable for the above; scale, 1 in. to the foot.

DRAWINGS RECEIVED.—Ivy, Dum Spiro Spero, Tom, Ignotus, Truth, Opus, E. V., One for Dot, Skill in Riches, Byculah, Maslwich, Mustapha, Excelsior, H. D., Frat, Rolls, Merit, Sleights, Hamlet, Gable End, Sam Slick, Random Shots, Semper Idem, Pupil J., Francis, H. in circle, Go Bo, Oliver Twist, Peter, Pharaoh, Ambition, Ernest, Yarra Yarra, Ever Onward, N., Spur and Win, Fidelis, Broad Oak, S. D., Deva, A Skull, Juno, G. od Luck t your Fishing, Just my Luck, Circle in Square, E. D. in circle, Trident, Byculah (2), Tom Finch, Fidelis (2), Spes, Othello, Nemo, Peter (2), Veritas Vincet, Try in Shield, Edmund, Ambitious, Pallium, Adventure, Bean Stalk, 1881, C. in circle, Student M., Beta, Ir-hman, Tristram, Zeld, Edward, Rest and be Thankful, Old England, Mary Jane, Nil Desperandum, In Hoc Signo, &c., Fred, Benachie, Semper Idem (2), Eos, To be or Not to be, Justice for Scotland, Cobbler's Wax, Hal in a square, Folle-Farine, Bunthorne, H. d, I Fain would Climb, &c.

RECEIVED.—Dum Spiro Spero (we cannot alter the size of paper), B. E., Ivy, G. F. U., Gubb, J. L., H. D., Chip, W. H. B. A., G. E. H. (Yes).

Correspondence.

WHY PROVINCIAL ARCHITECTS DO NOT JOIN THE R.I.B.A.

To the Editor of the BUILDING NEWS.

SIR,—Whatever shortcomings there may have been in past years, the present council and members of the R.I.B.A. seem so earnestly determined to improve its status and its morals, that the letter signed "A Provincial Architect,"

which appeared in your last week's issue, demands, I think, some attention from that body.

With regard to the subscriptions being the same for both London and provincial members, I do not see that it should act unfairly on the latter. If the Institute succeeds in its endeavours, the question will not so much be access to the library, &c., but the honour of belonging to a corporate body containing the best members of the profession.

I can scarcely agree with "A Provincial Architect" that "it is a mistake to suppose that the public look upon membership of the Institute as a guarantee of professional standing." He will find, I think, that even among the members themselves, who are, of course, able to accurately gauge the value of the initials—that some sort of confidence is placed in members, which would not be otherwise accorded to unknown men; and, I venture to say, that the public are not quite so unmindful of the value of members of a body (which certainly contains the flower of the profession), as to ignore the fact of membership altogether, and to attach no importance whatever to it. It rests quite with the members themselves to make the public regard the initials after an architect's name as a sure pledge of honesty and professional probity.

The proposition of "A Provincial Architect" to give country members "a greater voice in the council" is a fair one; but if he will remember that the present list of members of council contains the names of John Honeyman, E. G. Paley, Alfred Waterhouse, and Thomas Worthington, he will see that the country members are excellently cared for. His other proposition to "have provincial branches and hold congresses in provincial towns, that the provincial public may know more of the R.I.B.A.," is one which the council might I think well consider; but to "seek union with provincial architectural societies," is scarcely the work of the mother Society: it should be the earnest wish of infantile societies to seek union with the representative body, and so obtain lustre from the reflected light of that luminous centre.

That improvement in the status of the Institute will arise during the reign of the present President is not a matter of doubt with any who heard his vigorous address.—I am, &c.,
WM. WOODWARD.

SIR,—With considerable satisfaction I observe this question being reopened, concurring as I do in every line of your correspondent's letter of last week. There is no possibility of avoiding being somewhat personal in dealing with this question. The constitution of the Institute was never as elastic as it should have been to embrace the profession generally in the provinces. It was made infinitely worse by a mistaken policy of "reconstruction," so-called, of the Institute, set on foot and carried through with a high-handed disregard of all argument or remonstrance from without during the presidency of Mr. Charles Barry. May it be the distinguishing feature of Mr. Street's reign to remove the obstacles and stumbling-blocks then set up so unfortunately, and to sweep into the circle and influence of the Institute the great mass of the practising architects of the kingdom.

Extreme cases will best prove the logical working-out of the "reconstruction" policy in raising the subscription of Fellows to a uniform four guineas per annum. Writing from this *Ultima Thule* of provincial practice, I may instance the case of myself and several friends who have retired from the Institute after having exhausted all resources of argument and remonstrance. The distinguishing initials, "F.R.I.B.A.," are of some account and solid value in London; but of what account are they here, where an indifferent, and possibly scoffing public, accustomed to alphabetical decorations to names in abundance, neither known nor care for their significance. Then, of course, there are the *Transactions*. But will any unprejudiced member of the Institute appraise their value as literary stock-in-trade at more than 10s. per annum? After that, there is the inward moral satisfaction of supporting the dignity of the profession in London. What is that worth in money value? There our privileges cease. If we desire to enjoy the communion of our Fellows at the Institute, to exercise our rights of hallot, use its library and rooms, or attend meetings, we can do so at the

cost of £10 expenses for each occasion, and 24 hours of sea and land journey. A movement was set on foot here successfully to bring into the Institute every practising architect of good standing. The "reconstruction" policy came on shortly after, which, *more Ilbernicus*, we did not fail to remonstrate about. The result, that all the local fellows of the Institute, except one or two, resigned, aggrieved, as they felt they had some right to be. It is sheer nonsense to contend that this objectionable inequality of benefit does not apply in degree to all provincial architects more or less. What I venture to suggest as the lines on which a real reform and reconstruction should be are these: Not to seek unduly for the increase of the number of Fellows of the Institute. Let that distinction be a real distinction for architects of proved eminence. We cannot all be eminent and distinguished, but we should be all within the influence and recognition of the Institute for uniformity of respectable practice and many useful ends. What we want is a United Kingdom list of registered members of the Institute. Into this, endeavour should be made to sweep every provincial architect of decent repute, competency, and irreproachable professional conduct, admitted by the recommendation of trusted Fellows of the Institute, by ballot or examination; the annual subscription maintaining such registration to be one guinea, or even a more moderate nominal fee; the privileges to be awarded therefor as generous as the Central Executive could give for the money. This, I believe, would be a practical step towards obtaining legal recognition of such a status. The "dentist's art," to which I have before referred, is nearly exactly analogous and encouraging as a precedent for bringing about the legal recognition of a hitherto irresponsible and legally unrecognised profession as we are now. I believe that the moral influence over the profession and power in the State of the Institute would be enormously increased. Local societies, it should be remembered, too, must be maintained, and these have to be supported by provincial architects, as well as subscription to the central body. I feel sure, if Mr. Street will recognise the fact that there must be a special constitution to embrace widely the architects of the provinces, raising rather than lowering the status of a Fellow of the Institute, he has both the ability to lay it down in detail and the vigour to carry it.—I am, &c.,

THOMAS DREW,
Ex-Fellow and Member of Council R.I.B.A.
6, St. Stephen's-green, Dublin, Nov. 30.

SIR,—I may supplement your correspondent's letter of last week. I was elected a Fellow some time ago, and though I never set foot inside the Institute since I was a pupil in London, and never, that I am aware of, derived any benefit, directly or indirectly, from membership, I continued to pay my subscription till the authorities passed a resolution to double it. I think I paid, as a Fellow, for seven years or so, in addition to a donation of £5 to the library fund. When it came to be a question of "double or quits," I made up my mind to quit—the joke had gone quite far enough for—

EVEN AN F.S.A.

Dublin, Nov. 26.

ANOTHER BEAM FROM ST. MARK'S AT VENICE.

SIR,—We have such distinct evidence of the degree of architectural refinement to which the Greeks had attained, that we were not taken by surprise in the discovery of those curves of optical direction which have been so well illustrated by the labours of Mr. Penrose and Mr. John Pennethorne. The important work of the latter gentleman, which, at the hands of Mr. John Robinson, had received such careful delineation, will be in the recollection of your readers, as will also the singular discoveries of Mr. Street, Mr. Stevenson, Mr. Ewan Christian, and others, with reference to the "wavy lines," and other very remarkable optical refinements in the west front of St. Mark's at Venice, which structure, your readers will bear in mind, was not erected by the Greeks at the zenith of their art-culture.

I had, until the appearance of the article in your last issue, entertained serious misgivings as to whether or not all the subtleties of St. Mark's had been yet discovered, and it was, therefore,

with rapture that I read that studious essay signed "Védécé," which shows that to him who can read between the lines, and has time and energy at his disposal, there yet remains in St. Mark's a fund of undiscovered subtleties.

This time it is the Porta della Carta of St. Mark's—"the studied inclinations of the upper members" thereof—to which our attention is directed; and omitting, for the sake only of brevity in this letter, the mathematical workings which "Védécé" has supplied, we shall find that, if we could stand about 350 yards down the piazza, away from the porta, and looking at the lateral mouldings at the top of the finial, which forms a pedestal for the statue of Justice, those mouldings would be found to be inclined about 1 in 18 towards the beholder. When we have quite recovered from the effects of this stupendous discovery, we may contemplate the subtlety in the medallion over the arch-head, which contains the figure of St. Mark, where the climax of optical refinement is reached in the inclination forwards of that medallion of about 1 in 18, and, as "Védécé" very truly remarks, with regard at least to the Porta della Carta, the "arrangement" indicated takes the matter out of the reach of dispute.

Then to show how all is in harmony, we go on to notice the "lateral pinnacles or needles." Most unfortunately, however (and here we can rest a little to sympathise in the grief of Messrs. Street, Christian, and Stevenson), one of those needles "has suffered some restoration," and has probably been built vertical, but with intense gratification we note that the other "has its axis leaning forward 30 millimetres in a height of 1.26m," and before we leave the Porta della Carta, let us remember with deep regret that the "lower part of the structure, and the wall rising up behind it, are strictly vertical."

Of course, Sir, in all such matters of refinement in architecture, we must consider the "motive" which alone can justify their "raison d'être," and although "Védécé" has not pointed out the detrimental consequences which would have arisen had the mouldings, &c., referred to, *not* been "nodding" towards us, still we can quite see that much of the beauty would have been otherwise lost, and we are more in the debt of "Védécé" because it has been left to him to discover that "about 305 yards down the piazza" is the point from which the Brothers Bons directed the "nod."

I have scarcely a doubt that when the biography of "Védécé" is written, proper attention will be paid to that portion of his life when he grappled with, and ultimately succeeded, in bringing before the world the grand secret of the 305yd., and I am quite willing to subscribe towards the insertion of a brass or other means of spotting this 305yd. It is true that 305yd. is not, as a rule, a distance from which one can satisfactorily study the subtleties of such a building as St. Mark's; but still there it is—there is the point, and we must be thankful that we have at last found it.

But why did "Védécé" leave this Porta della Carta so suddenly? Did his eagle eye omit to discover the other subtleties of that composition? Let him, when next in Venice, take up a position—say a little less than 305yd. from the Porta, and in a direct line with the centre—neither to the right nor to the left of it—let him have erected a staging, or have a couple of men with a pair of steps, sufficiently high to bring the tops of the columns carrying the tracery within the arch under the medallion containing St. Mark, immediately on a level with the human eye; he will then find, I think, that the first column on the left of the centre is inclined to the centre. The exact amount of that inclination is not for me, but I should be extremely obliged to "Védécé" if he will obtain from the Venetian gentleman who has so kindly supplied him with measurements for his essay similar measurements for my discovery, so that your readers may be in possession of mathematical accuracy on the point. I wish it to be clearly understood that the inclination of the column referred to is not towards the beholder, but towards the first column on the right of the centre, and the "nod" in that direction is "clearly out of the reach of dispute," and shows to what astounding realms of refinement the Venetian builders of those days had reached.

Another very remarkable subtlety (this time not optical, but structural) "Védécé" failed to

notice in his essay. When columns are employed to carry a considerable weight of stone, such as in the tracery of the window over the Porta della Carta, it is customary to give them apparent support at the bases; the four columns, however, carrying this tracery all rest upon a string or sill carried through the full width of the window, thus giving a palpable idea of weakness to points where idea of strength is required, and destroying the more graceful proportion of the lights which would have been obtained had the columns been carried down to the level of the base of the shafts carrying the arch mouldings. The exact inclination which this string or sill will in various directions at some future time discover to another "Védécé," I am not now in a position to say; but the point from which the "nod" may be measured will probably be less than 305 yards down the piazza.

But after all, Sir, we need not go to Venice to feast on these subtle charms of refinement. Only the other day, in Victoria-street, Westminster, a very distinct inclination of a large flank wall in the direction of property belonging to another owner was discovered. The wretched adjoining owner—utterly lost to all regard for subtlety in workmanship—had the effrontery to consider that the inclination referred to might, in the event of his one day requiring to erect a building upon his own land, interfere with its verticality, and I believe that he was hard-hearted enough to claim a considerable sum of money because of this overhanging on his land. I have not before me the exact dimensions of the inclination; but I believe it was about 1ft. in 86ft., and its unique concord with the surroundings could be ascertained at a point distant about 10 yards from the façade. Should, however, "Védécé" wish to further and more accurately investigate the "nod" of the wall referred to, I have not a doubt that the owner of the building of which it forms a part, or the architect or builder, will, on his tipping the *wink*, be very happy to furnish him with exact measurements.

Another subtlety cannot have escaped the observant in London. If the observer will take up a position at the corner of any street, just on the granite curb, and carefully consider the line of lamp-posts on that side of the way, he will find that out of perhaps 20, one at least will be inclined somewhat to the centre of the roadway, or to the centre of the pavement, as the case may be. This is a subtlety which sometimes forms the ground of very earnest conversation between the gas company's official and the parish surveyor; and "one" may have at times noticed an endeavour on the part of the latter to ascertain and furnish the former with the exact measurement of the "nod." I have in my mind an instance where the inclination of a lamp-post was about 1 in 4—and that in a little picturesque thoroughfare off Drury-lane—showing that, even in squalor, all ideas of "inclination" and "nod" had not been abandoned.

A final example of subtlety of workmanship may occasionally be met with even in such apparently inartistic productions as suburban cottages and villas. The "inclination" or "nod" of chimney-stacks in directions sometimes towards the beholder, and sometimes the reverse, must have arrested the attention of the studious—and in carefully considering the proportions of the inclination, he may have noticed slight, but still apparent, inclination in some of the walls to assume lines and angles not precisely those which the commonplace architect, only caring for strictly accurate setting out and workmanship, would desire; and what a glorious and comforting idea it is to think that if these examples can only be kept up for a sufficiently long period, they may form the subject of earnest consideration and mathematical elucidation by the future seeker after refinement in architecture.—I am, &c.,

WM. WOODWARD.

THE PRESERVATION OF ANCIENT BUILDINGS.

Sir,—All men who love their country and are proud of its history, ought to be grateful to you for your consistent efforts to avert destruction from the glorious monuments in which so much of that history stands recorded.

But are you not a little hard on the Society for the Protection of Ancient Buildings, and on Mr. Canon Venables, as regards Tewkesbury Abbey? If they have been—I do not admit

they have been—over-zealous in defending what perhaps will not, after all, be attacked, is not that a fault on the right side?

Indeed, with the example of St. Alban's Abbey before us, it is impossible to be too vigilant. The time has come to ask whether any further sacrifice is to be made to the spirit of perverse self-sufficiency and bumptious ignorance which has been allowed to patch up St. Alban's in a style hardly worthy a third-rate conventicle.—I am, &c.,

EDM. HUTH, WALTERS.

Christ Church, Oxford, Nov. 28.

BUILDING-STONES OF SCOTLAND.

Sir,—I have read with great pleasure your report of Mr. Gowan's lecture on the above subject. He says, in his concluding remarks, that one lecture would not exhaust the subject. This is perfectly true; it is next to impossible to crowd into the short space of a lecture, even a meagre description of so many quarries and different classes of stone.

I suppose it is for this reason that Mr. Gowan dismisses Dumfriesshire, with its many valuable stones and extensive quarries, in a few lines.

My only object in troubling you with these few remarks is to point out to your readers the great similarity in chemical analysis, of the Dunmore, Polmaise, and Plean stone, and the Corsehill (Dumfriesshire) red stone, the comparisons being as follows, viz.:—

CORSEHILL.	
Silica	95.24
Alumina	5.5
Peroxide of iron	1.28
Carbonate of lime	1.40
Carbonate of magnesia	1.23
Moisture56
100.27	
PLEAN.	
Silica	95.64
Peroxide of iron	1.62
Carbonate of lime	1.20
Carbonate of magnesia52
Moisture60
99.58	

Corsehill stone is now extensively used in London and the provinces, and is much admired for its beautiful colour and texture. Craigleith is too well-known to need comment.

Of the Plean and Dalmeny stones, I may state that if more extensively used, they would be found to stand the London atmosphere, and contrast well in colour with the Dumfriesshire stones.—I am, &c.,

SAMUEL TRICKETT.

THE GLASGOW COMPETITION.

Sir,—As the drawings in the preliminary competition are now in, a few observations relative to the final competition may not be out of place.

The first thing that suggests itself to me is that the architect assessors would give more satisfaction, and act with more independence if they would, after selecting the first ten designs, hand over the mottoes to some one entirely independent of the competition, who should return the plans to their authors. This would, I feel sure, allay any heartburnings that might otherwise arise should a London or Glasgow architect be placed first.

Another matter is that the number of drawings in the final competition should be restricted to, as nearly as can be, the amount of the premium, so that the competition shall not resolve itself into one of long pockets, but one of brains. I feel sure that many competitors will join me in the assertion that already the competition has cost them fully one half the amount of one of the premiums.

In conclusion, as long a time should be given in the final competition as in the preliminary one for the preparation of the drawings.—I am, &c.,

Nov. 29. A COMPETITOR.

PRELIMINARY COMPETITIONS.

Sir,—The point of my proposal, which I think "Vigilans" has overlooked, was this:—Assuming £150 to be inadequate remuneration for the labour of getting up drawings, &c., in the final competition for the Dublin or the Glasgow buildings, I would, by a declaration of the order of merit in the preliminary selection, afford those who might so elect an opportunity of withdrawing at the earlier stage with a recompense proportionate to their trouble so far. This, to my mind, would be not only equitable but charitable.

I fail to see anything more invidious in selecting designs in their order of merit in a preliminary competition than in a final one; nor do I see exactly how the best six or ten, out of 160 or 170, could well be selected without a judgment being formed by the assessors on their relative merits. The judgment having been formed, I see no good reason why each competitor should not be made aware of the relative standing of his design. This could be done by declaring the order of merit by the mottoes only (those of equal merit being bracketted together), and the names of the authors, if they need be declared at all, could be given alphabetically. This would convey to each competitor only the information that concerned himself. The assessors of course should have power to vary the order of merit in the final competition if they thought right.

I, for one, if my design occupied sixth or tenth place, would prefer to know it, as I should, if that case, most certainly distrust my chance of the prize, and would think twice about going further, more especially if by withdrawing I should receive an equivalent for my trouble up to that point. What should be done with the balance of the £150 may be a matter of opinion.

Amongst six or ten of the best designs in a large competition there may be some of fairly even merit; but No. 1, as a rule, is more than a neck in advance. If so, how is he to be overtaken, when in the final heat all in the race are restricted to the same rate of speed, so to speak? They must all run strictly within the line of their respective sketch designs, "and no other"—in fact, merely draw the same design over again to a larger scale.

It is all very well to call preliminary drawings, such as are required in these competitions, "sketches"; they are far more than sketches. Where elevations and perspective are drawn in ink outline to 1-20th of a foot to an inch scale, and sections likewise, so much accuracy is required that really all the assessors need is a magnifying glass to convert these so-called "sketches" into carefully-drawn 1/16th scale drawings without further troubling the competitors. Such drawings should be sufficient in themselves to decide any competition on.

My proposal was not, as "Vigilans" puts it—viz., "that say seven competitors should," but that any competitor *might*, withdraw on the terms I suggested. No doubt every competitor enters the lists in the first instance with some idea of his design being successful. But if in the preliminary contest, and on good authority, it was made evident to "Vigilans" that his design was *no better*, even he, I think, would be over-sanguine and unwise to punish himself by further contention. If, however, he should entertain such a high opinion of his own production as to think that by merely enlarging it in scale he could change places with No. 1, my proposal, if adopted, would not preclude him from the venture.

A. B. C.

TESTING TRAPS.

SIR,—I find that I am expected to say something on the experiments which have recently been made with closet-traps at Messrs. Pullen and Son's works, Penton-place, Newington Butts, and I shall be glad if you will grant a space in your paper for that purpose. The public are very much indebted to you for the liberal way you have opened your columns this year to the subject of plumbing, and especially for ventilating this traps question—for good trapping is the key to sanitary plumbing.

I must admit that I have not seen any of the experiments made at Messrs. Pullen and Son's; but from what I gather from the published reports—which are somewhat conflicting—I should say the experiments are incomplete. There is a difference of 25 per cent. in the depth of the dip of the \square -trap, for one gives it as 1 in., another as 1 1/2 in.; and the difference in the depth of space between the basin-plug and the water-line of the 4 in. "patent east lead trap" is greater still, for it is given at almost every inch between 6 in. and 14 in. There is also a disagreement between your report and that of the *Builder*. In the third paragraph from the bottom of the third column in your last week's issue, p. 690, you state, in speaking of the endeavours to unsiphon Beard and Dent's 4 in. traps, "with the ventilating aperture on the top of traps open and the valve closed, the charge of water unsealed the trap to the extent of 1/2 in." Does this mean that the water was lowered in the

trap half an inch, leaving it with an inch water-seal? Or if the trap had 2 1/2 in. seal (as stated in your report, 37th line down from top of third column, page 690), the water-seal of this trap is really 1 1/2 in. (but perhaps, by accident, it has got distorted), then 1 1/2 in.? Or does it mean that the water was siphoned out 1/2 in. below the seal of the trap? In the report given in the *Builder*, it is stated (commencing at the 30th line from top of third column, page 679): "The round-pipe or S-Trap (Beard and Dent's) was provided with a 2 in. ventilating-pipe between the water in the trap and the junction of the arm with the down soil-pipe, but charges of water passing down the latter under the same condition as before did not disturb the water in the trap." I am quite positive that this would be the case in well-formed round-pipe traps; but more of this later on.

According to the published letters and reports, the experiments for finding out the displacement of water in a trap by the discharge of a valve-closet fixed upon it, have been made without a proper service of water to the closet-basin. Now, if anybody were called in to see such a closet, he would order water to be laid on to it immediately, or insist upon its removal. With a proper supply of water to the valve-closet, the result of the loss of water in the trap under it would have been very different to that reported, for though the previous contents in a Beard and Dent's 4 in. trap would have been driven out (an important advantage over the D-trap) by the water from the basin falling quickly upon it, the incoming supply to the basin would have re-charged the trap, either through the basin-plug or valve, or through the overflow-arm.

In the first edition of my book, "Dulce Domum" (published in 1877), I called special attention to the great liability of Beard and Dent's 4 in. "patent east lead trap" to siphonage, and nowhere in that book—or in the second edition of it—is it shown fixed under a valve-closet; but I did not fall back upon a \square -trap for fixing under valve-closets! I illustrated a much better form of trap, as I think, the "Mansergh" trap—though I should not be satisfied with that trap now, for it is not self-cleansing enough. After stating that any plumber could make this "Mansergh" trap, I go on to say: "This trap is specially adapted to prevent a too great siphoning action in the passage of the discharges through the waste-pipes or soil-pipes." "It is specially constructed for *valve* (the italics are in the original) water-closets and slop-sinks, where the discharge is sudden and direct into the trap. . . ." The illustrations in the first edition show the square-pipe "Mansergh" trap, fixed under *valve-closet*, and the illustrations in the second edition, the improved "V-dip" or "anti- \square -trap." But as I said at the lectures—and nothing said there have I to unsay here—round-pipe traps are perfectly safe against siphonage, i.e., the water cannot be siphoned out of them when properly ventilated, to rob them of an efficient waterlock or "seal" by discharges of water sent through the piping on which they may be fixed, or into which they may be branched. Nor can the water be driven, knocked, or "momentumed" out of such traps,

FIG. 1.

when properly made and ventilated, as shown in Fig. 2, by a discharge from any water-closet fixed upon them. I showed some specimens of such traps at the lectures, made by hand, i.e., traps bent and formed out of "patent" pipe for valve-closet and other uses; though the traps shown were of smaller size than those generally used, as I prefer traps to be as small as practicable for better cleansing purposes.

The reason why Beard and Dent's 4 in. \square or half \square -trap (the one experimented with, and illustrated in Fig. 1) is unsuited for fixing under *valve-closets*, is that its contents are easily knocked out. It is safe enough to use under the "Artisan" and "Wash-out" kind of water-closet. This 4 in. "patent east-lead trap" is faulty in form, for its rise to its outlet is much too easy. The small size "patent east-lead traps," 2 in. and 1 1/2 in., both \square 's and ∞ 's, are right enough. The water from a *valve-closet* basin, especially when it has an extra large outlet, falls flat upon the water in the dip-pipe A, and drives the standing water of the trap forcibly against its too sloping side B, which, glancing off to C, as shown by the arrows, instantly runs away, leaving the trap uncharged, unless sufficient water follows the discharge from the basin in a more broken form to re-charge it. But this would not occur in a round-pipe trap, formed as shown in Fig. 2—i.e., with the rise

FIG. 2.

to its outlet nearly vertical. The body part of such a trap being made U-shaped, the water driven up against the dome of the outgo would partly fall back again and help to re-charge the trap. It is the easy rise to the "outgo" of Smeaton's "Eclipse" trap which accounts for that trap losing its water; this could be remedied by bossing back the outgo and making the rise to it vertical.

Though it is of the utmost importance that traps should hold their "seal" in every treatment they are likely to receive, it is equally important that traps should be self-cleansing, or they will become so many "dangers to health." The \square -trap, the "Helmet," and even the improved \square -trap are non-cleansing traps; that is, such traps will require two or three flushes of water to thoroughly cleanse them after a body of soapy water or excremental matter has been passed into them—what they may do with stones and flannels is not the question. My small "V-dip" closet-trap, which I had at one of the lectures, can be cleansed by one flush of water from a valve-closet basin, and this trap cannot be unsiphoned, though unventilated by a discharge of a valve-closet, fixed upon the same stack of piping; nor can the water be driven, knocked, or "momentumed" out of it though unventilated, by the discharge of any water-closet (valve-closet, or others) fixed upon it, even though the space between the basin-valve and water-line of the trap be 15 in. But this "V-dip" trap is not proof against siphonage under every condition, unless ventilated; nor, in fact, is the improved \square -trap. I have had a \square -trap made up on the lines laid down by Mr. Davis at the discussion, and tested. The trap was fixed on about a 50 ft. stack of soil-pipes, at about 38 ft. from the bottom. About 12 ft. above this trap a 4 in. \square -trap was fixed on a short branch of 3 1/2 in. pipe leading into the same soil-pipe. By discharging about 16 gallons of water from a small bath (the one used at the lectures), through the upper trap, by means of a closet-plug, the water in the \square -trap was drawn away from the dip during the whole time of the discharge, and was lowered appreciably, and that, too, with the top end of the soil-pipe quite open. The same experiment was made with a 2 in. air-pipe on the top of the soil-pipe, and in one discharge of the bath the trap lost 1/2 in., leaving 1/2 in. "seal" in the trap, without any air-pipe on the top of the soil-pipe; the water was drawn out below the dip, leaving the trap without any "seal"; but with Pullen's east-lead \square -trap fixed in place of the improved \square -trap; but though the water kept in a very agitated state and lowered in the trap, it could not be unsealed—but, anyone seeing the disturbed state of the water in this trap during the

discharge from the bath, would never allow a \cup -trap to be fixed without ventilation. I could fill your paper with the experiments made, all of an interesting character. I had a \cup -trap fixed on a branch near the foot of the soil-pipe, and the soil-pipe trapped, and without "foot ventilation," a discharge from a valve-closet, fixed in lieu of the bath, drove the water out of the trap to the height of 3ft. and 4ft.

Besides the evil of fouling there is danger in using any trap having a dip-pipe inside its walls, as in the \cup -trap the "Helmet," the "improved" \cup -trap, and the "Eclipse" trap; for any defect or leakage in the dip-pipe would not show itself—i.e., though the dip-pipe might be defective, and allow soil-pipe air to pass through it, there would be no escape of water to show such defect, the pipe being inside the box part of the trap; but a defect in a round-pipe trap, or in a "V-dip" trap would show a water leakage at once. That dip-pipes inside traps do become defective, and, therefore, dangerous, the illustration, Fig. 3 will show.

FIG. 3.

This trap has only recently been cut out from where it had been fixed under a valve-closet, and I intend sending it to the Parkes Museum of Hygiene, University College, Gower-street. The dip-pipe is eaten away all round between the water-line and the top of the trap, as shown in the wood-cut, and the soil-pipe air would have had an easy passage through it to the house, as shown by the arrow. If this trap had been ventilated, the gases would not have eaten the dip-pipe away, and destroyed the value of its "seal," showing that ventilation is worth its cost, even apart from its value in preventing siphonage.—I am, &c.,

S. STEVENS RELLIER.

TESTING TRAPS.

SIR,—In your last issue I notice two letters on testing-traps, the first seeming intended to confute my arguments, but as it is quite beside the point I pass it over.

In the second I am pleased to see that Mr. Emptage acknowledges his error with regard to the \cup -trap, and which was published in your journal Oct. 22nd—viz., that beneath a valve-closet was the safest place to fix a round \cup -trap. I think this is due to my having shown him my drawings, which you publish in this week's article, when in his company on the 19th instant. It is very gratifying to find that I am making substantial converts daily.—I am, &c.,

P. J. DAVIES, H.M.A.S.P.

SIR,—As one of the committee at the experiments carried out at Messrs. Pullen's on the 19th inst., I beg leave to refer to the results. The principal trials were made in connection with the valve-closet upon the centre stage, the first trap tried being the Eclipse, with $\frac{1}{2}$ n. seal, 13in. drop, and unventilated; one gallon of water discharged very suddenly unsealed the trap. A 2in. vent-pipe was then added to top of outgo, when, after doing his utmost, Mr. Davies was compelled to acknowledge that he could not untrap it, the least seal left being $\frac{1}{2}$ in.

The next trap tried was Beard and Dent's \cup or half \cup , 12in. seal and 13 $\frac{1}{2}$ in. drop; it was tried both with and without ventilation, and was untrapped by Mr. Davies under both conditions. The helmet-trap was then placed in position, $\frac{1}{2}$ in. seal and 13in. drop, and unventilated. This trap was not affected by the flushes.

The next trial was with an unventilated \cup -trap, 23in. seal upon the top stage, fitted with a sharp basin, drop 6in.; this was also untrapped by means of the plunger by Mr. Davies. It was the opinion of some of the committee that Mr. Davies, by the suddenness of his flushes, did not give the trap under the valve-closet a fair trial. I perfectly agree with them; but, at the same time, a trap to be safe must be secure against all attacks to which it is possible in practice it may be subjected. There are, however, other conditions in connection with these experiments which must be taken into consideration before the results given can be fairly valued; for instance, take what, in my opinion, based upon actual experiment, is one, if not the

most, vital point—viz., the unusual amount of drop given between the valve and water-line of trap—viz., 13 $\frac{1}{2}$ in. This is neither necessary nor sanitary; the Helmet and Eclipse, when fixed in the ordinary way, have a drop of only 10 $\frac{1}{2}$ in., while the round-pipe trap, owing to the ease with which the dip-pipe can be cut down, can, excepting in very rare cases, be fixed with a much less drop. Why, then, with these experiments so great a drop is given I cannot understand, excepting from the knowledge of the fact that it is fatal to the round \cup and Eclipse, and does no damage to the Helmet, but rather assists it.

Now, the \cup -trap proper has not been introduced at all into these experiments. I understand Mr. Davies to say that he had not tried it; had he done so he would have found that it would when ventilated have defied all his efforts to unseat it, notwithstanding the drop was greater even than what he gave to the \cup .

As I am firmly convinced, from my own experience, that this matter has not been fairly brought before the public, I now give to Mr. Davies the following challenge, provided the Messrs. Pullen will grant the use of their scaffolding and apparatus for the purpose, I will undertake to prove before a committee:—

1. That the Helmet-trap is not to be relied upon, unless protected by a soil-pipe ventilation.
2. That a \cup , or half \cup -trap can, when properly ventilated, be made perfectly safe when fixed beneath a valve-closet.
3. That a ventilated \cup -trap can be fixed beneath a valve-closet with any length of drop, and will hold its seal against the most severe attacks to which it can be subjected.
4. That a ventilated \cup -trap, fixed with its outer leg upon the top of 45ft. of soil-pipe, is perfectly safe, either under a valve or a direct-action closet.—I am, &c.,

Margate, Nov. 26. DANIEL EMPTAGE, S.E.

SIR,—In reply to Mr. Emptage, letter dated Nov. 21, respecting the alteration in his statement as to height of fall of water, I think it strange he did not correct the error of his former letters, for he was shown a Beard and Dent's \cup -trap so fixed that it has 23in. seal, and where the plunger is only 6in. from water-line in trap. If he comes to our place simply for the purpose of being critical, I ask the gentleman in all honour to be accurate when behind our back, and when asked to correct his errors to do so properly.

With regard to Mr. Hart's statement, contained in his letter of November 21 last, the Beard and Dent's \cup -trap unsealed every time, to the extent of from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. As to water supply, the w.c. was and is supplied through a $\frac{1}{2}$ in. and not $\frac{3}{4}$ in. pipe, direct off the Lambeth Water Co.'s main, at over 60ft. pressure; and I have never, in the whole of my experience, ever used $\frac{1}{2}$ in. pipe for water. As to the hose, he could not have seen it, because there is such a remarkable difference between $\frac{1}{2}$ in. canvas rubber hose and a $\frac{1}{2}$ in. hose, I must put it down as a mental error. I may state that Mr. P. J. Davies pulled up the handle of the closet in the usual manner, and dropped it from his hand in the way anyone would in testing a closet. Mr. Hart, as one of Beard and Dent's men, should know that if a closet-handle will not fall of its own accord, the closet is imperfect, as the handle should fall back quickly. I would mention that Mr. Davies did not work the handle on Monday, when the final tests were made. Probably this may interest Mr. Hart. I will not pretend to tell anyone that the tests were intended to prove the efficiency of \cup -traps. Our scaffold and stack of pipes were put up simply to test traps. I must conclude by informing all intending visitors that the scaffold cannot stand much longer, as now that the stormy season has set in, I know not how soon we may be compelled to pull it down. Such being the case, I trust that all local surveyors will avail themselves of the opportunity to really examine the difference between efficient and non-efficient forms of traps.—I am, &c.,

J. PULLEN, jun.

73, Penton-place, Walworth,
London, Nov. 28.

SIR,—I have been much interested with the articles and correspondence on this subject which have appeared in your paper recently; and being busy with a slight addition to my residence, I had a favourable opportunity of making a simple test. I beg to give particulars, which may perhaps be of some interest.

I have had one of Tyler and Son's valve-closets, with siphon-trap (Fig. 3 in their catalogue) fixed; it is on the first floor, connected to a vertical soil-pipe, with short bend, about 10ft. down to drain, and soil-pipe continued, full bore as V.P., about 10ft. higher; the trap unventilated, with $\frac{1}{2}$ in. water-seal, and $\frac{1}{2}$ in. from valve to water-luo. I made the following tests—viz.:—

No.	Conditions.	Result.
1	2 gals. water put into basin (full to overflow), and plug suddenly drawn	Trap unsealed $\frac{1}{2}$ in.
1a	Do.	Do., $\frac{1}{2}$ in.
2	1 gal. water put into basin, and plug suddenly drawn	Trap left with $\frac{1}{2}$ in. seal.
2a	Do.	Water left level with bottom of dip of trap.
3	$\frac{1}{2}$ gal. do.	Trap left with $\frac{1}{2}$ in. seal.
3a	Do.	Do.
4	1 gal. water put into basin, plug drawn, and basin flushed with another gallon	Trap left with $\frac{1}{2}$ in. seal.
4a	Do.	Trap left with full seal.
5	$\frac{3}{4}$ gal. do., and flushed with another $\frac{3}{4}$ gal. ..	Do.
5a	Do.	Do.

The above tests were made before the water was laid on to the basin; but the following were made after it was connected—viz.:—

No.	Conditions.	Result.
6	About 1 gal. water in basin (quantity of constant after flush), plug drawn, and basin flushed for about 10 seconds	Trap left with full seal.
7	Do., but flushed only for 1 or 2 seconds	Do.
8	Do., but plug dropped instantly, without any after flush	Trap unsealed $\frac{1}{2}$ in.
9	Do., and lot of paper, and flushed till all cleared away, and for a second or two after.	Trap left with full seal.

The results of these tests appear to show that under the ordinary conditions of everyday use of such apparatus, the after flush makes good any unsealing that occurs from the first rush of water.

—I am, &c.,
Nov. 30.

JAS. ROBINSON.

SIR,—Having occasion to be in London for a few hours on the 21st inst., I accidentally happened to be present when the experiments described upon page 690 were made, and I can corroborate the general fairness of your report. I find, however, that upon again reading over Mr. Davies's report on page 540, I cannot agree with all his statements, deductions, and conclusions—e.g., he says on page 510 that when the top \cup -trap was left off "it was found impossible" with the top of the soil-pipe closed to empty the top siphon-trap, because it had 3in. of dip, while the \cup -trap, having only 1 $\frac{1}{2}$ in. of dip, rather allowed air to pass through itself. Now, in my presence, when the basin above the \cup -trap was emptied, and the soil-pipe tight and closed at top, the water was at once sucked out of the siphon-trap near it, considerably below the water-seal. I think, when Mr. Davies formerly experimented, the slip of this siphon-trap was not air-tight. I do not see that Mr. Davies is exactly right in saying, on page 540, that the \cup -trap can afford to help others "without interfering with its own efficacy," as it loses half its water-seal when so doing. Still, it may have enough left for general practical purposes in prevention of bad air passing the dip-pipe.

In regard to Mr. Davies's conclusions upon page 511, that the experiment he describes (and those I saw) "prove that the \cup -trap is the only reliable trap for valve-closet work, or any closet or sink where large quantities of water have to be thrown down at once, and that the \cup -trap is quite unreliable for these same purposes," I fear he is too hasty in this assertion, and is "calculating without his host," for I have to state that so far as the siphon-trap is concerned the experiments yet published are only partial, and do not exhaust the subject, and I am astonished to find a person with such a general knowledge of the various forms of traps in the market as Mr. Davies has published such a conclusion or statement while other forms of siphon-traps, such as Mr. S. S. Rellier's anti- \cup -trap, have not to be tested, more especially as this form of siphon-trap is recommended to be used against momentum and siphonage in Mr. Rellier's work, "The Plumber and Sanitary Houses." I am sorry to have to differ thus far from Mr. Davies, but to give the question of "Which is the

best and safest form of trap?" fair-play. Messrs. Davies and Pullen must complete their experiments, and not stop in the middle of them.

In regard to the mode of conducting the experiments, I consider such fair enough for the purpose. It is, in fact, more useful than trying them with the water running into the basin all the time the basin is being emptied, for although generally the case in practice, it does not always happen.

Then as to the results of the experiments made thus far, it must be admitted that the \square -traps retained a water-seal under circumstances and tests in which the particular forms of the siphon-trap and Smeaton's trap lost their water-seal, but the question of the effect of improved shapes has yet to be tried. Seeing improved forms of the \square -traps were experimented with, why were not improved forms—already public—of the siphon-trap also experimented with? Seeing they were not, justice to the question and to the public demands further experiments. As for Smeaton's trap, it may be classed with the \square -traps as having the same fault, viz., that the tongue or dipping foul-air-barrier is out of sight and may have a hole in it, making the trap useless, where not seen. For this reason, and because I consider the siphon or pipe-trap the cleanest, it would only be (with my present ideas) in some exceptional case, as where I could not get a ventilating-pipe put in, that I would think of using either a \square -trap or a Smeaton's; and if Mr. Hellyer's style of trap would act in such circumstances as well as the \square -trap, then I should not use a \square -trap at all.

Ventilating the outer side of the trap prevents concentration of the sewage gas and quick corrosion of the lead, and also lessens or perhaps practically stops diffusion of gas through the water; hence, non-ventilation of a \square -trap has a bad effect. The worst feature in any fitted-in trap, however, is loss of water-seal, and the trap must be so suited to its situation as to resist that, or it is a sham and a "trap" in other senses than the right one.—I am, &c.

Glasgow, Nov. 25th.

W. P. BUCHAN.

WESTMINSTER ABBEY.

SIR,—Your notice of the restoration of the north portal reads as if the work was complete. Such is not the case; the central portal only being partially so, the figure-work of which is only just commenced. The masonry of the whole has been executed most carefully by Messrs. Piercy and Co.—I am, &c.,

W. BRINDLEY.

67, Westminster Bridge-road,
London, S.E. Nov. 30.

EARTHENWARE POTS BUILT INTO CHURCHES.

SIR,—Mr. Gordon M. Hills, in his recent interesting paper under this heading, seems to have overlooked three or four similar vases to those he described, which were found last year in the parish-church of St. Mary, at Luppitt, a small village upon a bold range of hills some four miles from Honiton, in Devonshire. Mr. J. H. Spencer, of Taunton, was the architect employed in the restoration of the building at the time; and I remember that drawings of the jars in question, which were of about 4in. diam., were made by Mr. R. Medley Fulford, F.R.I.B.A., of Exeter. Probably yet other examples exist.—I am, &c.,

Exeter.

HARRY HEMS.

SUNDAY ART EXHIBITION IN EAST LONDON.

SIR,—The exhibition of works executed by students of the City School of Art, which was opened on two Sundays in December last, having proved very interesting to a large number of people at the East-end of London, we have great satisfaction in announcing that arrangements have been made for again opening the Exhibition on Sundays.

The Exhibition, which is the twenty-fifth Sunday Art Exhibition opened under the auspices of the Sunday Society, will be held in the Skinner-street Hall, Bishopsgate, and will be open from 3 to 6 o'clock p.m., on Sundays, December 4th and 11th. Admission will be free (*without ticket*), and we are pleased to be able to state that in addition to the work of the students some valuable pictures from the collection at South Kensington Museum will be exhibited.

In order that the widest publicity may be secured for this effort to provide innocent recreation on the leisure day of the week, we ask you to insert this letter in your columns, seeing that the facilities in London for visiting collections of art are far too limited, and that the want of open museums and art galleries on Sundays is especially felt by the inhabitants of crowded districts at this season of the year when our climate so often practically closes the parks and gardens to them.—We are, &c.,

WILLIAM ROGERS, M.A., Chairman } City School
R. H. HADDEN, B.A., Hon. Sec. } of Art.
THOMAS BURT, M.P., President } Sunday
MARK H. JUDGE, Hon. Sec. } Society.
9, Conduit-street, W., Nov. 30.

Intercommunication.

QUESTIONS.

[6798.]—**District Surveyors' Charges.**—A garden wall dividing four properties belonging to three persons was condemned by the Metropolitan Board of Works as a dangerous structure, under the 18 and 19 Vic., cap. 122, sec. 72, and the question I wish to submit for your opinion is whether the district surveyor's fee of 20s., provided for under Part II. of second schedule of above-cited Act, is chargeable upon the whole structure or upon each of the owners, who in this case are three (but might have been six), or, in other words, is the district surveyor entitled to the sum of £1 or £3 for surveying the two sides of a garden wall one brick in thickness?—E. H. C.

[6799.]—**Contracts.**—Will someone kindly reply to the following? In a contract for laying out a new cemetery, the boundary fence consists of a dwarf stone wall, with stone piers and palisades between. A portion of this fencing is omitted, and an iron fence, 5ft. high (costing a little less than that originally intended) is substituted. This iron fencing is ordered by the architect from a firm of ironfounders and fixed by them. The account is certified by the architect and sent on to the contractor for payment; the original wall is deducted from amount of contract, and the iron fencing added. The usual clause is inserted as to extras and omissions. The point at issue is, Can the contractor charge a profit in the bill of extras on the ironfounders' account?—E. C.

[6800.]—**Liability of Builders.**—I should feel obliged if any gentleman could give me any information upon the following case:—A building is put up by contract; the final certificate is granted by the architect, and the balance paid the builder. Some time after completion (say, six months) one of the outer walls is observed to be falling forward, and continues to give until ultimately it has to be taken down and rebuilt. It can be proved that this wall was not built plumb according to contract, and that the builder knew, or should have known, this. Is the builder liable for the cost of rebuilding the wall? Has a similar case ever been tried? If so, any information as to where I could obtain particulars would greatly oblige.—ONE IN DOUBT.

[6801.]—**Professional Practice.**—Will some reader of the BUILDING NEWS kindly inform me if it is usual to give a client a copy of the bill of quantities, or a priced copy of the bill of extras and variations if asked for? It is not usual, on what grounds can they be refused?—ISQUIER.

[6802.]—**Fowl Yard and Houses.**—Will any of your readers kindly inform me as to the best mode of building houses and constructing yard for fowls where a large number are kept, say, 2,000 fowls, the kind of material best adopted, and the plan of the different houses, with run to each; also as to provision and construction of nests and perches, &c., as I have to prepare plan for same, and should like to know the best means of accommodating such a large number? Is there not some peculiar method employed by the French people in the construction of such houses?—BLACK HAMBURG.

REPLIES.

[6793.]—**French Casements.**—Yellow deal would be preferable to pitch pine; the turpentine in the latter throws off the paint and leaves the wood exposed. On Nov. 22, 1878, Mr. Aston Webb gave a lecture on windows at the Architectural Association. Perhaps "Reader" will find this of use. I should strongly advise him not to use Smith's patent water bar; the hinged flap as often as not gets shut outside the sash. This happens if the flap is in the last raised before the sash is closed; the hinges becoming clogged with dust or anything is sufficient to prevent the flap lying flat upon the sill, so even for casements which do not go down to the floor, they are not to be relied on, but for French casements they are a snare and a delusion, and I thought they had become obsolete. About half way up Dover-street, on the right-hand side going up, there is an hotel (a red-brick building with stone dressings), where "Reader" can see these water bars in working order; he will find about every other window improperly shut.—CHARLES F. MOXON.

[6784.]—**Extras.**—Under the circumstances, the particulars of which, however, are almost too meagre to form an exact opinion, it seems probable that the client would not be bound to pay for the extra work, unless at some time or other he tacitly or otherwise invested the architect with sufficient discretionary powers; but the contractor, before suing the architect would do well to see whether he could prove that his claim is for accessories and not for work irrelevant to that which he has contracted to perform. In the latter case it is essential that he holds some kind of drawing or written order for the extra work. If the contractor has been incautious in making additions without an authorising document, the architect must have been remiss in allowing the work to proceed and not giving it; whilst, to complete the all-round responsibility, the client should either have repudiated his architect's views, or else have chosen at the outset one in whom he could have reposed a little more confidence.—W. J. CHASTRY.

[6793.]—**Luminous Powders, &c.**—"Mac" will find an article on Luminous Paint in the BUILDING NEWS of 6th February, 1880. In case he hasn't the number to refer to, he may write Messrs. Illies and Horne, 31, Aldermanbury, E.C., for information.—W. U. O.

[6795.]—**Memorial.**—Pulpits, fonts, lecterns, and reredoses are regularly placed in churches as memorials, with or without inscriptions to that effect. Any one of the four may be made for the sum mentioned by "Memorial," should his design not be too ambitious. If photographs of the departed gentleman exist, a bust may be well modelled and sculptured in statuary marble at a similar cost.—HARRY HEMS.

[6794.]—**Problem.**—Lease granted for 14 years. Terms: £1,050 paid down, 250 per annum the first ten

years, £300 per annum the last four years. The lessors' interest at 4 per cent. compound would be £6603.689, viz.,
£1050 for 14 years 1818 285
£250 per annum for 10 years 3001 325
Four years comp. int. thereon 569 959
£300 per annum for 4 years 1273 920

£6,603.689
Then £6,603.689 will give the annual rent for 14 years at £471.7. If B. takes the lease from A. at the end of 10 years, his proportion of rent would be 4 years at £471.7, equal to £1886.80; but as he has to pay the last 4 years' rent, viz., £300 per annum, he is entitled to a reduction of £1273.9s. 2d., leaving a balance of £612.88. This amount not being due until the end of the lease, the present value is £237.889, or £237.17s. 10d.—G. B., Lincoln.

[6794.]—**Problem.**—The following is, I believe, a correct solution of the problem:—

The price of the lease for 14 years is £1,050
The total rent to be paid in the 14 years is 3,700
Total £4,750
£4750 for 14 years is equivalent to £339 2-7 per annum.
Now the proportion of the total sum which A. should pay is 10 years, and
£339 2-7 = £3,392 6-7
The rent paid by A. for 10 years and
£251 = 2,500
Therefore A.'s proportion of purchase-money = £892 6-7
B.'s proportion of total sum = 4 years
and £339 2-7 = 1,337 1-7
The rent paid by him for 4 years and
£300 = 1,200

£157 1-7
The answer to "Cocker's" question is, therefore, £57 2s. 10d. as the sum B. must pay. For the sake of proof, seeing "Cocker" has had so many different answers, suppose that the lease is worth £500 a year to both A. and B. for their respective terms (of course, all such questions of depreciation of value, &c., are set aside in the question), it will be found that both A. and B. will reap an equal profit of £160 14s. 3d. per annum. The value may be more or less, but the profit per annum will be the same to both A. and B. thus proving that a proportionate price has been paid by each.—W. U. O.

[6794.]—**Problem.**—Price of lease £1,050, term 14 years. Rent first 10 years, £250 p.a. Rent last four years, £300 p.a. Lease to be sold after first ten years.
Total amount of rent paid by A. = £2,500
Do. Do. to be paid by B. = £1,200

Do	for the 14 years =	£3,700
If proportionate amount on	£3,700 =	£1,050
"	"	1,050
"	"	3,700
"	"	1,050 x 1200

£340 10s. 9d. 14 37.—J. R. R.

[6796.]—**The Sanitary Institute Examination of Surveyors.**—The office of the Institute is at 9, Conduit-street, W., and your best course would be to apply there for further information respecting the examinations.—S. S. J.

The new dockworks at Maryport were greatly injured on Wednesday week during a gale, the sea carrying away masses of the concrete wall, the inside sand embankment, and the tramways. The loss, which is estimated at from £15,000 to £20,000, will fall upon the contractor, Mr. Doherty.

Sundry serious-looking cracks having been observed in the fine old façade of the Old Guildhall at Exeter, Mr. Edward Ashworth, architect of that city, was commissioned by the town council to report and examine the same. His report was read at a recent meeting.

The parish-church of Llansadwrn, near Menai-bridge, was reopened on Tuesday after a complete restoration from the designs of Mr. Kennedy, the diocesan architect. The contract was executed by Mr. Robert Jones, Bangor.

Mr. Harry Hems, of Exeter, has been elected an Associate of the Society of the Sons of St. George, at Philadelphia, founded in A.D. 1771, and one of the oldest in America.

LEGAL INTELLIGENCE.

BREACH OF BY-LAWS.—Alfred Wm. Price, builder, of New Southgate, appeared on Monday, at Highgate Police-court, on an adjourned summons, charging him with having infringed the by-laws of the Hornsey local board by erecting four dwelling-houses on the Archway-road Estate, Hornsey, with 9in. external and party walls, instead of 13in. walls. The facts were admitted, but it was alleged that the houses were built in accordance with the plans passed by the local board. This, however, the surveyor proved, was not the case, and it was then shown that the buildings were not commenced by the defendant, and that he had completed them in accordance with the plans handed to him by the first builder, which only showed 9in. walls. The Bench said they had nothing to do with that. The by-laws had been infringed, and the defendant was responsible. The solicitor for the prosecution, in answer to the Bench, said he believed the local board would compel the defendant to carry out the by-laws by making him pull down the walls, but he could not say for certain, as the whole question was at present under the consideration of a committee. A fine of £2 10s. and costs was imposed.

THE BEER FREESTONE COMPANY.—DAMAGES CLAIMED FOR EXTRAORDINARY TRAFFIC.—At the Axminster Police-court on Tuesday week, the Beer Freestone Company, Limited, of Seaton and Beer, were summoned, at the instance of the Axminster Highway Board, for the amount of £25 5s. 6d., incurred in repairing the damage to certain roads in the parishes of Seaton and Beer, in consequence of the excessive traffic over them by order of the defendants. The Beer Freestone Company possessed a quarry in the parish of Beer, and had caused stone to be conveyed in large blocks along the highway to Seaton Station. This traffic within the past six or twelve months had increased considerably—double or treble—and the result of the extra traffic and the extra weight was that the road from the quarry to a particular point, called Town End Cross, had been considerably damaged, and extra expenditure had been deemed necessary. The extent of the road was about half a mile and 85 yards. In previous years the expenditure on that piece of road had been comparatively small, but now, in the course of about six months, £25 5s. 6d. had been spent in consequence of extraordinary traffic. From Lady-day, 1880, to Lady-day, 1881, £11 2s. 7d. was expended on the road, and in the five previous years the sums of £9 10s. 1d.; £3 2s. 6d.; £7 5s.; £5 12s.; and £3 5s. respectively were expended. Instead of two or three tons of stone, as originally, there were now six, seven, eight, and even nine tons at a time conveyed over the road. That weight had been taken over the road three and four times a day, so that there would be about 30 tons of stone passing over the road daily. The waggons drawing the stone were pulled by four, five, six, and seven horses, thus showing that there had been a tremendous increase of traffic. A variety of cases with reference to extraordinary traffic had been tried, and the outcome of them all was that the ordinary traffic of a road was to be the standard. The quarry had been almost disused at one time, and then suddenly a large business was developed, and about 100 or 150 tons of stone a week were taken over the road in question. He maintained that the stone traffic over the road being suddenly opened up was extraordinary, because the road was not adapted or made for the purpose. In conclusion, Mr. Tweed said the Bench would have to determine whether the sum claimed was reasonable in regard to the average expense of repairing the highways in the neighbourhood. The average cost of repairing the roads per mile was £6 4s. The Bench retired to consider their decision at six o'clock in the evening, having sat nearly seven hours. Upon returning into Court, the Chairman said the Bench considered that the traffic had been extraordinary and excessive within the meaning of the 23rd section of the Highway Act, and they ordered the defendants to pay the sum claimed, together with the costs. Mr. Ward intimated that a notice of appeal would be given in due course. Mr. Tweed said there was another case instituted by the Seaton Local Board against the company, and asked whether the Bench would hear it that night? One of the magistrates: Not to-night for me, thank you. (Laughter.) The case was adjourned for a fortnight.

BROKEN BRICKS: WHO IS RESPONSIBLE?—The Barham Brick, Lime, and Cement Company (Limited) v. Henry Medgett Eytton, architect, Ipswich. Action—tried at Ipswich County Court, Nov. 22nd, before Mr. F. R. xburgh, Q.C., and a jury—to recover £21 5s. 11d. for bricks sold and delivered. Plaintiffs sued for the price of certain bricks which were sent by rail from London to Ipswich, and which arrived in a damaged condition, and the question being likely to arise as to who was liable for the loss, the defendant had given the railway company notice to appear or be bound by the decision in the cause. His Honour said the question of the liability of the railway company could best be settled by an independent

action, and dismissed the railway company from the action, reserving the question of costs for a time, to see if any action were brought against them by either plaintiff or defendant. The plaintiffs are manufacturers of ornamental bricks in South London, and sued the defendant, an architect at Ipswich, for £21 5s. 11d., the price of certain patent bricks sold to him. The bricks were ordered by Mr. Eytton for use in a house which was being erected from his designs for Mr. H. H. Kingdon, on the Westerfield-road, Ipswich. In April, 1881, the bricks were ordered in a letter requesting them to be sent to Mr. Hayes, of Ipswich, the builder. The bricks, as ordered, were sent off by the Great Eastern Railway at Liverpool-street station, and arrived at Ipswich on the 14th July. The builder, Mr. Hayes, went down on receiving notice of their arrival, and found that the bricks were considerably damaged, the "arris" being chipped and broken. Defendant telegraphed that the bricks had arrived damaged in transit, and could only be accepted as paving-bricks. The secretary of the company replied that bricks were sold as delivered into trucks in London, and that after such delivery no claim could be entertained for damages, defendant's remedy being against the Railway Company. Neither party claiming the bricks from the Railway Company, they have been standing in the truck in the goods station yard at Ipswich ever since, and the plaintiffs now sued for the price. The questions in the case were—first, as to the terms of the contract, whether the delivery was to be at Liverpool-street Station; and secondly, if so, whether the bricks were properly packed in the trucks by the plaintiffs' men. With regard to the first question, Mr. Cheak deposed that it was the uniform practice of the company to limit their responsibility to the delivery at the stations; and that in previous transactions with defendant this was the contract. The plaintiffs did not pay carriage. The plaintiffs' workman, William Taylor, who packed the bricks in the railway truck, and William Breeden and Thomas Fairman, carmen, were examined as to the way in which the bricks were packed, which was with straw between the layers, but without any between the separate bricks of each layer; and said that from their experience that was the safest way to pack bricks. Mr. Bennett, of the firm of Rother and Co., said the way described by the men was the proper way to pack the bricks. It was the usual practice to sell for delivery at the wharf or railway stations. Similar evidence was given by Mr. Alfred R. Bristo, an employé of Messrs. Eastwood and Co., and Mr. T. E. Cheak, traveller to plaintiffs, proved that he saw the bricks at Ipswich, and that when he saw them a number of them in the top layer were broken, but those underneath were in fair condition. Mr. Poyser said for the defence that plaintiffs were seeking to make his client pay for what was really useless to him. The damage to the bricks was clearly not done by him. It was the fault either of the plaintiffs in not properly packing the bricks, or the Railway Company in negligently conveying them, and the right thing would be for the plaintiffs and the Railway Company to fight the case out between them. He contended that there was no acceptance by the defendant of the bricks, but that on the contrary immediately upon arrival he telegraphed refusing to accept them, and argued that if the case set up by the plaintiffs was admitted it would necessitate the sending of someone to London to superintend the packing of bricks. The packing was improper for bricks of this description, the sharp edges, on which the proper carrying out of the designs entirely depended, requiring special protection. The defendant, Mr. Eytton, said he did not limit the plaintiffs in any way as to the expense of carriage or delivery; all he wanted being that the bricks should be sent down securely. He did not consider that the bricks were properly packed. There was not sufficient straw used, and none was put between the individual bricks, so that the "arris" of the bricks was injured, and they were rendered useless. Mr. H. H. Kingdon was also examined, and said the railway could not be blamed because the bricks were not properly packed. Mr. Hayes, the builder, also testified to the damaged condition of the bricks on arrival, and his opinion that they had been improperly packed, and similar evidence was given by Mr. Wm. Gladstone, builder, Ipswich, and Mr. Edgar Catchpole, builder and brickmaker, Ipswich, and Mr. R. Seeley, the railway goods agent at Ipswich, was called to prove that the truck was placed on a back siding to obviate frequent shuntings, and had stood still nearly the whole time it had been at Ipswich. The jury found that the bricks were bought to be delivered at Liverpool-street, and that there was not sufficient evidence to prove that they were not fairly packed. His Honour said that would be a verdict for the plaintiffs, and the further question was put to them whether any authority was given by the defendant to the plaintiff to make any special contract with the railway company as to the carriage of the goods, or whether they were to be carried in the ordinary way. The jury replied that the goods were to be carried in the ordinary way.

Judgment was then entered for plaintiffs for the amount claimed.

THE EMPLOYERS' LIABILITY ACT.—An action, entitled "Adams v. Nightingale," was brought at Southwark County Court, on Monday, by a carpenter for £200 for damages sustained by the fall of a scaffold. Mr. Fitzgerald was for the plaintiff, and Mr. Kemp, Q.C., and Mr. Macdonnell for the defendant. An interesting question arose as to the serving of the six weeks' notice required by the Act. The notice was left at a box or portable office in the defendant's yard after business hours, and never came to his knowledge. The judge ruled this not to be a good notice, and nonsuited the plaintiff.

THE SHOREDITCH PAVING DISPUTE.—"Griffiths v. Steel"—"Griffiths v. Holloway."—The hearing of the appeals in these actions came on before Lords Justices Brett and Bagge, and the Chief Justice Sir John Coleridge, on the 10th November and on the 28th November Lord Justice Brett gave judgment for the plaintiff as follows:—The first question is, whether we are of opinion that this jury was justified in finding malice in fact. Now there was an election on the point of taking place, or rather voting, as to who should have the contracts, and what these defendants, practically both of them, said was that the plaintiff ought not to have the contracts because, they said, he is a man who has been contractor before, and he has put mere rubbish into the road, he has put black mud into the road instead of what he ought to have put. Now they were entitled to make such a declaration, whether in fact it was correct or not, if they believed it to be true; but as to one of them he had a year before, according to the evidence, made a similar charge against the plaintiff, and had complained to the Chairman of the Committee, who had to deal with this question of roads, and thereupon the chairman and the surveyor had inquired into this matter and they had then told this defendant that his charge was not correct, and that there was no ground for it, and they warned him that he had better not make such a charge; and for a year, or nearly a year, he had remained satisfied with that explanation, that is to say, he had done nothing substantially to question it. But at the moment when the parties were going to vote and determine who should have the contract, he suddenly resumes the accusation and calls out, "Why, this man ought not to have the contract, he mends the roads with black mud." We think that the fact of his having made the accusation a year before, and of it having been explained to him then, shows that he was not making this statement at the moment he did on the present occasion for the purpose really and truly of instructing those who were going to vote, but that in a moment—I hardly know what to call it—of enthusiasm in favour of some candidate of his own he made this statement, not candidly for the purpose of instructing those who were going to vote, but for the indirect and improper motive of obtaining by the statement the votes for his own candidate, and reckless whether the charge he was then making was true or false. If so, that is evidence upon which a jury might properly find that he was not using the privileged occasion in the way it ought to be used; but he was using it for an indirect and improper motive, and that, therefore, he was guilty of malice in fact. But as to the other defendant, it seems to me that he made the same statement without any grounds which could be presented to his mind to justify him in making it, and he accompanied with that particular statement what he alleged he had seen, which was undoubtedly untrue; and it seems to us it comes to the same with regard to him—that he made this statement for an indirect purpose, regardless whether what he stated was true or not, and that, therefore, the verdict against both these defendants was a proper verdict. But the verdict against each of them was for damages to the extent of £40, that is that this plaintiff was entitled to damages practically of £80. Now we have come to the conclusion, after considering this matter carefully and after consulting with the judges of the Divisional Court, that the election was not really influenced by what was said at all. The parties had all made up their minds before. It was not a deliberate malice; it was a malice that arose in the men's minds on the instant, and they gave way to a wrong and foolish desire to obtain the contract for their own candidate. We, therefore, do think that the damages were too high, and we think that what would be fair as to the damages would be to reduce them, but only to such a sum as should enable the plaintiff to indemnify himself, and show to anybody that the verdict was so substantial as to be a declaration that he was a person who was entitled to bring the action. On the whole, we have come to the conclusion that the damages in each case should be reduced to £15.

The Grantham board of guardians adopted last week plans by Mr. T. B. Watson for the enlargement of the hospital.

Our Office Table.

THE international exhibition at South Kensington of grates, furnaces, and other appliances for the scientific consumption of fuel was opened on Wednesday afternoon by the Lord Mayor. The Lord Mayor having briefly opened the proceedings, the report of the Committee was read by Mr. E. Hart, who gave a detailed account of the circumstances in which the exhibition was held, and of the manner in which the work of the two societies had been supported by public opinion and by the evidence of scientific men. The committee claim for the exhibition that it will tend directly to promote the better utilisation of coal and coal products, and that it will afford trustworthy information upon which a sufficient amendment of the existing law may be based. The Marquis of Lorne, Mr. Shaw-Lefevre, Sir H. Thompson, Lord Aberdare, Dr. Siemens, and others having spoken, the visitors proceeded to view the exhibition, which is housed in the galleries to the east of the Albert-hall, and of which our first notice appears elsewhere. The exhibit is roughly divided into six sections, of which the first contains open coal firegrates, stoves of all kinds, kitcheners, and kitchen-ranges; the second, gas-heating apparatus of all kinds; the third, hot-air, hot-water, and steam appliances; the fourth, gas-engines, boiler furnaces, and appliances for steam-engines and general industrial purposes; the fifth, anthracite, bituminous and semi-bituminous coals; and the sixth, all foreign exhibits, improvements in chimney-flues, and ventilating apparatus. It is proposed to award certain prizes and medals to the best exhibitors, and the arrangements under which these will be awarded will be made known as soon as practicable. Among the donors for this purpose is Dr. Siemens, who has offered a prize of 100 guineas. A ladies' prize of 100 guineas, divided into two sums, for the best domestic open grate and best kitcheners, will be given. The Society of Arts have offered a medal; the Manchester Association for Controlling the Escape of Noxious Vapours have added a prize of £50; and further prizes will also be offered.

MR. ROBERT RAWLINSON, C.B., the chief engineering inspector of the Local Government Board, according to the London correspondent of the *Manchester Guardian*, has lately been in very different health. Mr. Rawlinson is now much better, but it is not unlikely that he will at no distant date retire from the duties of his position at the Local Government Board. It is probable that in that event Mr. Rawlinson would be recommended to Her Majesty for knighthood. Mr. Rawlinson has had a long and useful career. His success at the time of the cotton famine is well known. He was Sanitary Commissioner with the British army in the Crimea, and assisted in alleviating the horrors of the disastrous winter of 1855-6. He has rendered important service in connection with the sanitary reform of the barrack system of India, and his recommendations upon the sewerage of towns have been adopted in many places in England and in other countries.

THE casting of the new bell for St. Paul's Cathedral has been completed at the Works of Messrs. J. M. Taylor and Sons, of Loughborough. Some 21 tons of metal was prepared. All being in readiness, three furnaces were opened, and liquid streams poured forth for four minutes and three-quarters before the huge casting was filled. The process being one of great delicacy and difficulty, the operation was kept strictly private. On Saturday evening the casting was steadily cooling down. When it is dug out it will weigh no less than 17½ tons. Some idea of its size may be obtained from the fact that the first Big Ben at Westminster weighed but 15 tons 8 cwt., and the second was two tons lighter; while Great Peter at York Minster is but 10¾; Great Tom of Lincoln, 5½; the previous big bell of St. Paul's, 5 1-10; that at Almutz 17 tons 18 cwt.; Vienna, 17 tons 14 cwt.; Erfurt, 13 tons 15 cwt.; Sens, 13; Paris, 12. The process of conveying the new bell to London will be one of some difficulty. The railway in this instance not being available, the casting will probably have to be conveyed by road.

At a meeting of the Sanitary Institute of Great Britain, held November 24, Prof. F. S.

B. F. DeChaumont, M.D., F.R.S., in the chair, the secretary read a list of the donations to library since last meeting, and Dr. Benjamin Browning, Mr. A. Roberts, of Sydney, and Dr. W. Robert Smith were elected Fellows of the Institute. Four members and associates were also elected, and four associates enrolled who had obtained the Institute's certificate as Inspector of Nuisances. Applications were read for ballot at next meeting. The Autumnal Congress and Exhibition is arranged to be held at Newcastle-on-Tyne in 1882.

It is announced that Mr. Ruskin has changed his plans with respect to the museum he has founded at Sheffield, and that it is his intention to devote the remainder of his life to making it about the most complete institution of this kind in the world. He has decided to send there his unique and priceless library from Brentwood, and a portion of the books and plates have already arrived. Plans for the extension of the buildings have been prepared, and a public subscription, which the Duke of Albany has promised to head, will shortly be opened to defray the cost of the enlargement.

THE Alhambra Theatre has undergone extensive repairs and alterations of a decorative and structural character. The building was erected nearly thirty years ago, by Prof. Hayter Lewis, for other purposes than those to which it is now devoted. The principal structural works which have now been undertaken, consist of the widening of the proscenium, the improvement of the accesses and staircases to the stalls, and an examination and strengthening of the main timbers and supports of the building. The width of the old proscenium had been limited by two of the iron columns supporting the main roof, but these have now been removed and new and more substantial columns carrying a deep iron girder under the base of the dome have been substituted. The works to the stage have also included the completion of a fire-proof concrete screen between the stage and the auditorium. The alterations to the approaches consist chiefly in the new and broader staircases giving access to the stalls; the alteration of the corridor to the boxes, and an increase in their number. Advantage was taken of the closing of the house, thoroughly to overhaul the whole of the construction, and the directors called in a civil engineer, Prof. Kennedy, of University College, to consult with their architects on the subject. The result has been that considerable works for the strengthening of the dome have been done, and all means taken to insure the safety of the fabric. The works were done by the contractor, Mr. Brass, of Old-street, St. Luke's, with the assistance of his foreman, Mr. Jones, for the constructional work; and his sub-contractor, Mr. W. Homann, for the decoration. Messrs. Perry and Reed were the architects.

ON Friday afternoon the fronts and sides of two partially finished shops in course of erection at the junction of Bedford Hill-road with the main road at Balham, fell down suddenly, slightly injuring two passers-by. The houses were being erected for Mr. Brown, of the saw mills, East Brixton, by Mr. Perham, of Brixton. The latter had made application to the Wandsworth District Board of Works in the usual course, for permission to build the two shops. The Board refused the request, as they wished the line of frontage to be set back 2ft. from that on which Mr. Perham proposed to build, and he therefore appealed to the Metropolitan Board of Works, whose surveyor had not yet reported on the matter. As Mr. Perham would not accede to the wishes of the Board, they refused, it is said, to grant him permission to place his scaffold poles in tubs in the road. He therefore carried his stages on beams, resting partly on the old garden-wall, remaining in front of the premises, in the other end passing under the first floor joists, on which an iron tie-beam had been laid to weight them down. On Friday the scaffolding began to work, and finally fell, bringing with it the end and side walls, and blocking up the road, but not doing so much personal injury as might have been expected from such an occurrence.

WITH the view of avoiding the bursting of water-pipes by freezing, a method of making them elliptical in section has been recently patented. As the water expands to form ice, it will alter the shape of the pipe, causing it to become circular in section, and therefore giving

more room for the ice. It is proposed to squeeze the pipes into their original shape, when by a succession of frosts they have been rounded.

CHIPS.

The town council of St. Helens, Lancashire, have applied to the Local Government Board for sanction to borrow £2,896 for work of street improvement. Mr. John Thornhill Harrison, C.E., held an inquiry on Tuesday at the town-hall into the matter. Full details were given by the town-clerk and surveyor with regard to the proposed improvements.

The Dockyard Church at Sheerness was gutted by fire on Saturday night, only the walls and tower remaining. The damage, which is estimated at £6,000, is attributed to the overheating of flue in warming apparatus.

The harbour extension works at Folkestone-pier were entirely washed away during the gale of Saturday night, including, it is believed, the foundation-stone laid a month since by the Prince of Wales.

The parish church of Blythburgh, near Southwold, one of the finest and most dilapidated examples of the semi-Flemish fifteenth century architecture of East Anglia, was closed on Sunday, under an order from the Bishop of Norwich, on the ground that the splendid hammer-beam roof is dangerous, and the walls damp.

A company has been formed for erecting an iron promenade pier on the north beach at Bridlington. The plans have been prepared by Mr. Joseph Firbank, C.E.

The students of the Gresley and Swadlincote science and art classes were presented with the prizes and certificates gained in examinations on Monday week. It was reported that 1096 drawings were sent to South Kensington in April, and gained two third grade and six second grade prizes. The late teacher, Mr. Cooke, has been appointed head master of the Sheffield school of art, and is succeeded by Mr. Bradbury, of Derby.

The local board of East Dereham made an inspection on Tuesday week of the newly-constructed works of sewerage, which have just been completed from plans by Mr. W. H. Nankivell, their surveyor.

The annual meeting and exhibition of works in connection with the Henley-on-Thames School of Art, was held on Wednesday week. The report stated that 201 students had joined since 1874, and there was an average attendance of 35 in the industrial class. The May examinations were not so successful as usual, as most of the students were recruits, but two second-grade prizes were gained. The Rev. W. Foxley Norris afterwards delivered a lecture on "Some higher influences of Sacred Art."

The Congregation of Oxford University finally considered and passed on Wednesday week a statute for the sanitary inspection of lodging-houses—a proposition which has awakened much sensitiveness in the local board and citizens generally. A controller of lodging will be appointed, and also a sanitary officer, who will not necessarily be a medical man. The delegates are empowered to call in special professional help, and to meet the expenses a fee of half a guinea per annum is to be paid by each student living in licensed lodgings—a fee which is estimated to realise about £100 yearly.

At the Norwich police-court on Friday, Henry S. Porter, a builder, was charged with stealing, in conjunction with another man, deeds of the value of £1,000, from a solicitor's office, where he had called on business. Defendant was remanded.

SMOKE ABATEMENT.

INTERNATIONAL EXHIBITION
AND TRIALS
of
SMOKE-PREVENTING APPLIANCES
at
SOUTH KENSINGTON.
NOW OPEN,

10 a.m. to 4 p.m. from 1st to 5th December, inclusive.
10 a.m. to 8 p.m. from 6th to 10th December, inclusive.
After the 10th December, Mondays, Wednesdays, and Fridays,
10 a.m. to 4 p.m. Tuesdays, Thursdays, and Saturdays, 10 a.m.
to 10 p.m.
Admission (including entrance to the conservatory), every day
except Monday, One Shilling. Mondays, Sixpence.

ROYAL INSTITUTE OF BRITISH
ARCHITECTS.—The Third Ordinary MEETING of the
Session will be held on MONDAY, the 5th inst., at 8 p.m., when
a Paper by Major Mant, Associate, on NATIVE BUILDINGS
AT THE GOLD COAST, will be read, followed by a Paper by
R. Phelps Spiers, Fellow, on THE WORKS OF THE LATE
MAJOR MANT, R.E., Fellow.
J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.
9, Conduit-street, Hanover square, London, W.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers. "Arrangement, Construction, and Machinery of Breweries," by W. Horns Kinsey. 7.30 p.m.
Royal Institute of British Architects. "Surveyor's Institution. "Land Legislation and Tenants' Improvements," by E. P. Squirey. 8 p.m.
Society of Arts. "Cantor Lecture No. 3. "Industrial Uses of the Calcium Compound," by T. Holm. 8 p.m.
TUESDAY.—Institution of Civil Engineers. "The Conservancy of Rivers; the Fen District of England," by W. H. Wheeler, M.I.C.E. 8 p.m.
Birmingham Architectural Association. "Chorini's address by H. H. McConnell. 7.30 p.m.
WEDNESDAY.—Sanitary Institute of Great Britain. First ordinary meeting. Announcement of award of prize for essay. Address by Dr. A. Carpenter. 7.45 p.m.
British Archaeological Association. "The Discovery of Ruins of Saxon Church in Gosforth Park," by Rev. Dr. Hoopell; "Excavation of Site of Carrow Abbey by Mr. J. J. Colman, M.P.," by E. Loftus Brock, F.S.A.; "Results of the late Malvern Congress," by T. Morgan, F.S.A. 8 p.m.
Society of Arts. "The American System of Heating Towns by Steam," by Capt. Douglas Galton, C.B. 8 p.m.
FRIDAY.—Architectural Association. "Harnacles," by Cole A. Adams. 7.30 p.m.

Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Only in Tins, labelled "Epps's Cocoa," Homoeopathic Chemist, London.—Makers of Epps's Chocolate Essence for afternoon use.

Lamplough's Pyritic Saline is refreshing, most agreeable, and the preventive and curative of FEVERS, RHEUMATISM, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the Maker, 113, Holborn Hill. *Use no substitute.* See Medical Testimony.

Holloway's Pills thoroughly purify the blood, completely cleanse the lungs, re-invigorate debilitated or vitiated nervous action, strengthen the muscles, and clear the brain. These excellent Pills are particularly recommended to all persons whose occupations are sedentary, or conducted in close rooms, and to the nervous, dyspeptic, and the low spirited.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to **CHARLES TRASK,** Norton-sub-Hamdon, Ilminster, Somerset. —[Advt.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates. General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country.—[Advt.]

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE.
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.
(See trade advt. on p. XXIII.)

TENDERS.

* * Correspondents would in all cases oblige by giving the address of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ADMIRALTY SERVICE. For the supply of 5,000 gun-metal corks, for the Lords of the Admiralty:—
Dennis, T. H. P. and Co., London and Chelmsford accepted £1,232 0 0.
(Weight of metal, about 27 tons.)

WALWORTH. For the construction of a service reservoir and intake works at Cullwilt, for the Bathurst Local Board. Mr. Thomas Roberts, Assoc. M.I.C.E., Fortmoad, engineer:—

Williams, J., Cullwilt	£1,62 0 0
Williams, J., Foston	1,198 0 0
Owen, S. P., Fortmoad	1,059 0 0
Williams, G., Harleth	850 0 0
Frayne and Co., Birmingham	850 0 0
Engineer's estimate	1,421 0 0

No tender has yet been accepted.

BATH. For the construction of a pipe sewer near Gurneo Gardens, under the City Corporation. Mr. A. Mitchell, borough engineer:—
Matthews and Jennings accepted.

BRIMINGBY, S.E. For the completion of the town hall, for the vestry. Messrs. Elkington and Son, architects:—
For g-sittings and chandeliers:—
Steele and Co. (accepted) ... 185 10 6

BECKENHAM.—For villa residence at Beckenham. Mr. F. West, Coombe-road, Croydon, architect:—
Copeland, Beckenham ... £1,594 0 0
Astell, Beckenham ... 1,988 0 0
Ward, Warrington ... 1,940 0 0
Smith and Sons, Norwood ... 1,928 0 0
Miles and Harper, Croydon ... 1,877 0 0
Marriage, Croydon ... 1,760 0 0
Taylor, Croydon ... 1,650 0 0

BERWICK-ON-TWEED.—For reconstruction of the carriage-way at Railway-street, between the entrance to the North British Railway Station; also for lowering footpath, &c., at the North-road, near Summerhill-terrace, for the Urban Sanitary Authority. Mr. James Lawrie, surveyor:—

Reconstruction of Railway street, labour only.
Preston, J. D., Reston, Ayrton ... £114 11 6
Brough, J., Berwick-upon-Tweed ... 43 12 6

Lowering of footpath, &c., at North road, labour only.
Preston, J. D., Reston, Ayrton ... £120 7 6
Brough, J., Berwick-upon-Tweed ... 47 6 0

BETHNAL GREEN.—For rebuilding No. 8, Bawn-street, Bethnal Green, for Mr. W. Witherden. Mr. W. D. Church, architect. Quantities supplied by Messrs. Nixon and Raven:—

Wire	£1,164 10 0
Taylor, J.	1,365 0 0
Tyerman	1,362 0 0
Godden	1,353 0 0
Steel	1,280 0 0
Shurmer	1,278 0 0
Sabey and Son	1,200 0 0

BROMLEY, KENT.—For erection of farm buildings, &c., Crofton Court, Bromley, for Mr. H. Norman:—
Taylor and Son (accepted).

BURRISLAND, SCOTLAND.—For additions to the engine-house at the harbour, being contract No. 2. Mr. Robert Henderson, harbour engineer:—
Aitkin, Merchiston (accepted) ... £142 0 0

CAMDEN TOWN, LONDON, N.W.—For fittings to the London and South Western Bank, Camden Town. Messrs. Edmeston, architects:—

Laacelles	£458 0 0
Jackson and Graham	456 0 0
Lucas	417 0 0
McLachlan and Sons	410 0 0
Dowsett	389 0 0

CANDIFF.—For enlargement of South Church street School, Candiff. Mr. H. C. Harris, St. Mary-street Candiff, architect:—

Burton, C., Bath	£238 0 0
Purcell and Fry, Bath	212 0 0
Jones Brothers, Park street	210 0 0
Bird, C., Canton	199 18 0
Davies, Cousins, Catwys (accepted)	198 0 0
Jones, J., Brook-street	190 0 0

CARNARVON.—For a proposed new villa, near Carnarvon, for the Rev. J. E. Jones. Mr. J. P. Mumford, architect:—
Edwards and Owen, Caerthraw (accepted) £185.

CROWBOROUGH.—For restoration and enlargement of All Saints' Church, Crowborough, Sussex. Messrs. Whitfield and Thomas, architects. Quantities by Messrs. Evans and Deacon:—

Card and Son	£3,492 0 0
Rowles	3,226 0 0
Vaughan	3,179 0 0
Parmer and Son	3,130 0 0
Cheseman	3,128 0 0
Hughes	2,990 0 0
Ringham	2,797 0 0
Morris	2,759 0 0
Paine, J.	2,650 0 0

CROWBOROUGH, SUSSEX.—For additions to the Hermitage, for Mrs. J. H. Barclay, Crowborough. Mr. Edwin T. Hall, A.R.I.B.A., 57, Moorgate-street, E.C., architect:—
Pannett and Sons, Tunbridge (accepted) £850.

DEBENSHIRE.—For the erection of a policeman's house and strong rooms at Llandudno-y-Mochant, for the county magistrates of Denbighshire:—
Huskey, C., Wrexham (accepted) £415 0 0

DEXTON, LANC.—For construction of a single gas-holder, 80 ft. by 21 ft., and a double gas-holder 80 ft. by 21 ft., for the Denton and Houghton Joint Gas Committee, Denton. Messrs. Vevers and Wharm, engineers:—

Newton, Chambers & Co., Leeds	£5,870 0 0
Blind and Sons, Bury, Lancashire	5,639 0 0
Willey and Co., Exeter	5,535 0 0
Horton, J. and T. Smithwick	5,475 0 0
Horsely Co., Tip on	5,400 0 0
Howard, D., West Bromwich	5,300 0 0
Westwood and Wright, Dudley	5,284 0 0
Tyldesley, J., Willenhall	5,000 0 0
Crayton and Co., Leeds	4,800 0 0
Pater and Co., Lincoln	4,575 0 0
Ashmore & White, Stockton-on-Tees	4,310 0 0

ENFIELD.—For the erection of a residence at the Ridgways, Enfield, for Mr. J. Eales. Mr. W. D. Church, 12, South-place, Finsbury, architect:—
Fairhead (accepted) ... £1,680 0 0

ENFIELD.—For the erection of a pair of semi-detached residences, at the Ridgways, Enfield, for the Rev. H. S. Toms and Mr. J. Garner. Mr. W. D. Church, 12, South-place, Finsbury, E.C., architect:—
Fairhead (accepted) ... £2,560

EVERSELY.—For alterations and additions, including new conservatory, &c., to Kite Croft, Eversley, for Mrs. C. A. Tubit. Messrs. Lovejoy and Watford and Crowthorne, architects:—
Harnsworth (accepted).

FINSBURY PARK.—For new roof and general alterations to the Cottage, for Mr. T. H. Finchampstead. Messrs. Lovejoy and Watford and Crowthorne, architects:—
Accepted tenders.

Bricklayer's and slater's work:—Harnsworth.
Carpenter's and joiner's work:—Bun.h.

FINSBURY PARK.—For alterations and additions at 3 and 4, Stroud Green-road, Finsbury Park, N., for Mr. Earle. Mr. W. Smith, architect:—
Shurmer ... £495 0 0
Dunford and Langham ... 484 0 0
Cole and Chart ... 425 0 0
S. Evans Bros. ... 415 0 0
Harper, J. ... 414 0 0
Steel Bros. ... 407 0 0
Mattock Bros. ... 33 0 0

GOSSPORT.—For the erection of boundary-walls and gates to villa, Bury Cross, for Mr. J. D. Hill. Mr. R. Peters, Wool Exchange, Colman-street E.C., architect:—
Butt, J., Gosport (accepted) ... £63 0 0

GREAT MALVERN.—For brick and timber work on the sewage farm, for the local board:—
Broad (accepted) ... £21 10 0

GREAT YARMOUTH.—For additions to shop, Market-place, Great Yarmouth, for Mr. G. P. Palmer. Mr. J. W. Cockrill, Glencoe House, Gorleston, architect:—
Isaacs, Great Yarmouth ... £1,153 0 0
Beech and Cork, Great Yarmouth ... 1,028 0 0
Norfor, Southtown ... 919 0 0
Cooper, Great Yarmouth ... 900 0 0
Davy, Great Yarmouth ... 890 0 0
Springall, Great Yarmouth ... 870 0 0
Howes, T., Great Yarmouth ... 866 0 0
Want, Great Yarmouth ... 849 0 0
Bray, J. T. W., Great Yarmouth* ... 780 0 0

GREENWICH, LONDON, S.E.—For warming St. Mary's Church, Greenwich, by hot-water apparatus:—
Edmonds, J. and Co., Lillie Bridge (accepted).

HALIFAX.—For the various works required in repairing and altering the Congregational Chapel in Harrison-road, Halifax. Drawings and quantities prepared by Mr. T. H. Farrar, Halifax, architect:—

Accepted tenders.
Joiners:—
Charnock, J. and Sons, Halifax ... £922 4 0
Plumbers:—
Naylor, J., Halifax ... 135 0 0
Painter:—
Binas, J., Halifax ... 1-8 10 0
Mason:—
Jenkinson, H., Halifax ... 72 0 0
Plasterers:—
Baneroff, J. and Son, Halifax ... 69 0 0

HECKMUNDWAKE.—For levelling, flagging, paving, sewerage, arching, and channelling, of Union-street, Heckmondwike. Mr. T. Gledhill, surveyor:—

Hirst, W. H., Ravensthorp	£160 0 0
Hirst, G., Dewsbury Moor	177 13 0
Oldroyd, W., Heckmondwike*	177 10 0
Surveyor's estimate	176 0 0

HORNSEY.—For finishing five houses at Middle-lane, Hornsey, N., for Mr. Elder. Mr. J. Farrer, architect:—

King	£947 0 0
Farnborough	802 0 0
Harper	790 0 0

IPSWICH.—For removal of buildings on site of Shire-hall yard proposed school, for the Ipswich School Board:—
Grimwood (accepted) ... £71 0 0

IPSWICH.—For erection of building as stay manufactory, Ipswich. Mr. E. Catchpole, architect. Quantities not supplied:—

Jones, Gloucester	£7,850 0 0
Cox, Ipswich	7,148 10 0
Beunett, J. and F., Ipswich	7,125 0 0
Girling, Ipswich	6,908 0 0
Catchpole, Ipswich	6,780 0 0
Gibson, Ipswich	6,750 0 0

ISLEWORTH, MIDDLESEX.—For (Contract No. 2) Gordon House Estate, Isleworth, about 3,850 ft. lineal of road making, 36 ft. wide, with kerbed paths and pipe drains; about 1.6 ft. lineal of widening road, with one path; a brick bridge, 30 ft. span, across tidal water course, for the United Land Company:—

Nowell and Robson	£5,338 0 0
Pizzey, J.	5,255 0 0
Killingback, C.	4,899 0 0
Cooke and Co.	4,754 0 0
Bull, J.	4,613 0 0
Wils and Stodart	4,570 0 0
Beadle Bros.	4,550 0 0
Wilkes and Co. (too late)	4,533 6 1
Huntley, D.	4,410 0 0
Neave and Son	3,945 0 0
Edton, G.	3,647 0 0
Acock, G.	3,557 0 0
Tomes and Wimpsey	3,557 0 0
Ford and Everett (accepted)	3,333 0 0
Atkin, S. (for road only)	2,730 0 0

ISLE OF THANET.—For the erection of three cottages and garden walls at Newington, St. Lawrence, for Mr. W. Spain. Mr. E. L. Egar, architect. Quantities supplied:—

Duckett, T.	£774 5 0
Hobbs, T. S.	731 10 1
Bugden, P.	535 10 0
Egar, T.	532 0 0
Cowell, B. J.	530 0 0
Newby Bros.	514 0 3
Bowman, H.	446 0 0
Cullen, E. (too late)	480 0 0
Port, W. H.	470 0 0
Horne, C. (accepted)	435 0 0
Redman, S. B.	430 0 0

LEAMINGTON.—For a new cottage at Llanrug, for Mr. J. Morris, Cwm-y-Glo. Mr. J. P. Mumford, Carnarvon, architect:—

Edwards and Owens	£135 0 0
Gilliths, J.	135 0 0
Williams, G. (accepted)	130 0 0
Price, P.	130 0 0
Williams, J.	115 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 9, 1881.

THE SUBJECT AND NEIGHBOUR
LANDS OF VENICE.*

DR. EDWARD A. FREEMAN has produced a book in which ably-written descriptive essays are rendered of still greater value by illustrations from the pencil of an artist and antiquary. The essays are the results of three journeys. The first was made in 1875, took in Dalmatia and Istria, with Trieste and Aquileia. This journey was made about the time the revolt of Herzegovina had commenced. Another journey to Dalmatia was made by Dr. Freeman in 1877, and in the present year, 1881, the author paid a third visit to Dalmatia and some parts of Istria and Albania, as also a large part of Italy. The illustrations have been made chiefly from Dr. Freeman's own sketches and partly from photographs, and consist of freely-drawn outlines slightly shaded.

Lombard Austria is first described. We have papers on Treviso, Gorizia, Udine, and Cividale, Aquileia and Trieste. We cannot spare the space necessary to do justice to the author's graphic descriptions of these South Slavonic lands. Writing on Trieste, "a rival of Venice which has in a low practical view of things outstripped her," Dr. Freeman speaks of the cathedral church of St. Justus, and "It is hard to conceive a building more uninviting without," he says. But the *duomo* of Trieste is not to be judged by the outside. "A broad and almost shapeless west front is flanked by a low heavy tower, not standing detached as a campanile, as it should stand in Italy, not worked into the church as it would be worked in England or Germany; but standing forward in a kind of Scotch fashion, like Dunkeld." The walls are embedded with fragments of pilasters and fluted Corinthian columns, entablatures, trophies, &c., the remains of the temple of Jupiter which has given way to the church of St. Justus. But the interior of this church is most remarkable. Dr. Freeman says, of his experience, "The first feeling is simply puzzlement. A nave of vast width seems to be flanked by two ranges of columns on either side; columns varying even more than is usual in their height, and in the width of the arches which they support. When we look within the two lateral ranges we are not surprised to find each ending in an apse with a noble mosaic; we are surprised to find the southern range interrupted by a cupola. The church is, in fact, two churches thrown into one. When they were distinct, they must have stood even nearer than the old and new minsters at Winchester." The north church was a basilica, with marble columns and capitals of Corinthian, though of different varieties; they all carry the Ravenna stilt in a rude form. This church is attributed to the time of Theodosius, though without direct evidence. The southern church is smaller, and has a Byzantine cross plan with a central cupola.

"From Trieste to Spalato," is the title of another very interesting chapter. The author describes his sail along the coast of Dalmatia, its thoroughly fresh and unhackneyed character, and he dips into the history of the country, which has been of a very fitful kind. The harbours of Trieste and Pola are visited *en route*. Zara, with its *duomo* and smaller

churches and narrow streets, is graphically depicted, and the author halts at Sebenico, a Dalmatian hill-side city on the coast. Here the streets are rich with architectural features—the piazza, the loggia, the cathedral with its mixed, but stately architecture, and its waggon roof of stone without buttress or external roof. Dr. Freeman agrees with Mr. Neale that the cathedral is a most remarkable and effective building. The proportions internally are noble; the height is great, and the "columns, though their arches are pointed, might have stood in any basilica at Rome or Ravenna." The details are a strange mixture of Late Gothic and Renaissance, rich with bits in both styles, side by side. Dr. Freeman justly insists upon the value of seeing a place twice if possible. The process of recollection fixes it on the mind. The great Justinian Basilica at Parenzo is touched upon, and Pola, another halting-place on the Istrian coast, forms an interesting chapter. The huge amphitheatre and the Porta Gemina, a sketch of which is given with its two wide arches and columnar front of the Corinthian order, bespeak the city as once a colony of Rome. One peculiar feature is here pointed out, namely, that the columns support an entablature without the architrave. The arch mouldings answered the purpose. Other peculiarities are mentioned in the amphitheatre, such as its situation on the slope of a hill, which slope supplied a natural basement for the seats on one side, though it did away with the lower arcade on this side. The Roman antiquities of Pola are its chief attraction save, perhaps, the *duomo*.

The paper on Zara, famous for its connection in the history of the Fourth Crusade, contains many allusions to the churches. The church of St. Anastasia, rebuilt in the 13th century, is a witness, says the author, "to the way in which the Roman styles long stood its ground, though here and there is a touch of the coming pseudo-Gothic, and what is far more interesting to note, here and there is a touch of the Romanesque forms of the lands beyond the Alps." The basilica has been much transformed. The choir is remarked for its rich Cinque-cento stalls, not unlike those of Wimborne, and essentially Northern. The crypt is very interesting as showing columns with only the bases finished and of Byzantine character, and the variety of columns in the main arcades, some being single, others clustered and twisted, and with Corinthian capitals, is spoken of by Dr. Freeman as peculiar. An exquisite Romanesque church as late as 1407 is mentioned, having three apses after the best models; and we are treated to a sketch of a tower of St. Mary's, a church of nuns, Renaissance in style. The tower is referred to as the only finished one in Zara; it is of Italian type, with midwall shafts.

St. Donatus is another remarkable building described; it is a round church now disused. Dr. Freeman believes it was built with materials contributed from the spoils of a pagan building, the so-called House of Juno. It has two arched stages of great height; the columns have Composite capitals and there is a triapsidal end. It forms one of the noblest round churches to be found, says the author, and the "so-called House of Juno is almost a rival of the so-called house of Jupiter at Spalato." Two interesting sketches are furnished one, of St. Vitus, Zara, an example of real Byzantine, with a circular tower at the crossing pierced with openings. The ground-plan is square, the four arms being square-ended without, and quasi-apsidal within. This building has been ruthlessly swept away to make a smart shop-front!

The paper on "Spalato" is well worth reading. Spalato is the centre of all historical and architectural associations on this coast; its Venetian walls and buildings contribute to make it so, no less than the city was the home of Diocletian of Rome. Like

her great mistress, Spalato marks an era. Dr. Freeman sketches its earlier history with the pen of the historian well versed in antiquarian lore. Describing the palace of Diocletian, the author says: "It was not in the city, it was not close under its walls, that Diocletian fixed his home.... Not on any hill-top, but on a level spot by the coast, with the sea in front, with a background of more distant mountains, and with one peaked hill rising between the two seas like a watch-tower,—did Diocletian build the house to which he withdrew when he deemed that his work of empire was over. And in building that house he won for himself, or for the nameless genius whom he set to work, a place in the history of art worthy to rank alongside of Iktinos of Athens, and Athenios of Byzantium, of William of Durham, and of Hugh of Lincoln." We could here, if space allowed, go on quoting the picture drawn by the author of this dwelling-place. The great bell-tower, which rises over the work, is feelingly sketched, with its shafted angles and stages, and the octagon termination. "Spalato Revisited" forms the title of another chapter, in which the author corrects a few points in etymology, and acknowledges that the name Spalato has nothing to do with *Palatium*. The *r* in the popular way of writing Spalatro is an intrusion, and is unknown to the country.

We have not space to follow the author into the accounts given of Salona, Traù, Curzola, Ragusa, and other places. St. John the Baptist, Traù, is an interesting building, of Romanesque design, according to the view. The cathedral is of the most finished kind of Italian Romanesque, but the tower is Venetian Gothic.

The architecture of Ragusa forms a separate chapter; the municipal and domestic buildings have never been described or illustrated in England, though the city claims a place in the history of architecture as the author shows. The tower of the Franciscan church sketched is a very fine specimen of Italian Gothic. The tower, as usual, rises to a considerable height, is marked by four stages, and is crowned by a small octagon cupola. Mr. Freeman says it shows how long the general type of the earliest Romanesque campaniles went on. The lower part has the appearance of 11th-century work: "Three ranges of windows with mid-wall shafts rise over one another, only they are grouped under containing-arches, in what in England we should call a Norman fashion." It is not thought earlier than the 13th century. The Venetian Gothic arcade of the palace is an interesting example of the style, and a sketch of it is introduced. We are certainly disposed to think, with the author, that the Ragusan front will better stand the test of minute study than St. Mark's. All the examples of this city point, says Dr. Freeman, to "the existence of a Ragusan style, to an unbroken Romanesque tradition, which could not wholly withstand the inroads of the pseudo-Gothic of Italy, but which could keep its place alongside of the intruder." Renaissance features are seen, but they never supplanted the earlier style—the round-headed traceried window and round-arched arcades always remained, and never gave way to Gothic.

"Venice in the Footsteps of the Normans" is the heading of the concluding chapter. Trani, Otranto, Corfu, and Antivari are sketched, and their Norman characteristics pointed out. The sketch of the arcade and triforium of Trani cathedral, with its triplets of round arches, is an instructive instance of the different way in which Norman influenced the architects; or, at least, the way the Saracen introduced Romanesque forms. The coupling of two columns under a single abacus in the arcade is certainly, as thought

* Sketches from the Subject and Neighbour Lands of Venice. By EDWARD A. FREEMAN, D.C.L., LL.D., &c. London: Macmillan and Co.

by the author, one of the features found in Saracenic work. The sketches given in this section are highly interesting examples of the Byzantine and Romanesque styles, and these chapters will be read with an increased interest from the remembrance of some of the political changes which several of the places mentioned have witnessed of late years. Dr. Freeman's volume, which is a companion volume to the author's "Historical and Architectural Sketches," is more than a guide-book: it is a collection of historical essays, heightened by illustrations of remains in lands and cities which will always have a permanent interest for English readers.

THE INTERNATIONAL EXHIBITION OF SMOKE - PREVENTING AP- PLIANCES.

[SECOND NOTICE.]

RESUMING our notes of the heating and smoke-preventing appliances at South Kensington, we now refer to a few gas-heating and other stoves of some merit. The gas-heating stove of Dr. Adams, exhibited by William Harvie and Co., of Glasgow, is constructed on a cellular principle. It consists of four concentric casings, two outside and two inside, and between these is an annular flue, made tortuous, by which the burnt products escape by an upper outlet. There are two air-inlets. The air which escapes warmed can be moistened, if required, by a rim of water at the top; but it is not burnt or over-heated by direct contact with the gas-chamber. A third combustion-inlet is so arranged that the air is warmed before combining with the gas, thus giving increased heat. The action of the stove can be controlled, and the heating-chambers are made of various sizes to burn the required amount of gas. We are informed this stove has been used in invalids' rooms and conservatories without injurious results.

Ewart and Son's "New Crown" boiler for the ordinary gas-flame, and the baths attached, are economical fittings; George's patent gas "Calorigen," shown by J. F. Farwig and Co., Queen-street, appears to be a great improvement on the ordinary gas-stove. The cold air from the outside of building passes through a pipe within the cylinder of the stove, and its upper part is coiled; the cylinder is attached to two pipes, which are connected to another cylinder of smaller size outside the building. The products of combustion are carried away by the upper of these two pipes, and the cold air coming down the outside cylinder supplies the air necessary for combustion. By this arrangement the coil becomes heated, and the air passing through it is warmed, and passes out at the upper end of stove into the apartment, while the gas products are carried away. The stoves can be used in bedrooms, and burn either coal-gas or coal, and it ventilates as well as warms. The "Slow-Combustion Calorigen" is another good modification, with a fire-chamber air-chamber at the back, and air-space all round the fuel-box. It burns coke or anthracite.

Dr. Francis T. Bond, Medical Officer of Health for Gloucestershire, is the inventor of the "Euthermic Ventilating Gas Stove." The stove is simple, and consists of a cylinder of convoluted sheet-iron, within which is an inverted cone of metal. The apex at bottom is connected with an air-tube for fresh air, while the gas-chamber surrounds the cone, and the heated products are made to descend a series of outside tubes of pillar-like form, and escape by a flue-pipe. We have examined the operation of this stove, and believe it to be one of the best in the market. It is made in a cheaper and smaller form, and, for sanitary reasons, we

have pleasure in bearing our testimony to the economy of its construction, and the large heating surface obtained. "The Euthermic Gas-Burner" is a capital appliance for cooking. It burns a mixture of gas and air, which can be reduced as required, and has the appearance of an argand. Dr. Bond's ventilating gas bracket is an appliance for rendering gas-burners innocuous. A hollow cone, open at both ends, fixed to a horizontal arm, or inlet-tube, communicating with the outer air is placed over the bracket. When the gas is lighted the heated air ascends through the cone, and induces a current of cold air through the tube, which mingles with the heated products of combustion and reduces their temperature, while, at the same time, the room is supplied with a current of fresh warmed air, making up for the loss of air consumed. We believe this very simple and adjustable appliance will remove effectually the evils attending gas-burners, and, for bedrooms, it appears to be indispensable to healthy respiration, as it insures a constant supply of fresh air. The London agents of these appliances is the Wilson Engineering Co., Holborn.

Dr. Siemens' gas and coke fire, manufactured by Waddell and Main, Glasgow, is a combination of gas and coke for grates for preventing smoke. The principle is in admitting a hot blast to the underside of the fuel. The cold air passes into a chamber under the fuel, and issues at the bottom of the front bar, impinging on a line of gas-jets. Deane and Co., of London-bridge, have a register grate for burning anthracite in the ordinary open fire. The smoke from bituminous coal is consumed by its being made to pass over the fire. There are side flues, which communicate with the bottom of stove, and the products are conveyed down these, directly below the fire. F. Hammond, of Chandos-street, shows a new smokeless fire in an open grate, on Dr. Siemens's principle. The peculiarity of the appliance consists in a copper back, and a wrought-iron dead-plate, the gas-jets being arranged along the bottom in front. It can be fixed on an ordinary grate. Michel Perret, whose "Radiating Fireplace" we glanced at last week, has also an "Immersed Grate," in which the bars are very close together, so that no fuel can fall through. The bars are immersed in a water-pan underneath, and the air passes between the water surface and the hot bars. There is a firebrick baffle or cover close to the fire at the top, which throws the unconsumed fuel down. Another noticeable plan of reducing the quantity of fuel, and of burning bituminous coals without much smoke, is shown by W. A. Martin and Co., of Blackfriars-road. The grate has movable sides, which can be shifted inwards, and so reduce the fire; the coals are put on only at the sides by projecting one of the movable hobs into the fire, and then withdrawing it, the space left being filled with fresh coal. The top of the fire is left undisturbed by this arrangement of stoking, and the fresh fuel does not emit much smoke. The "Ironbridge Controlled Combustion" grates shown by the Coalbrook Dale Co., in connection with their "Kyrle Fire," minimise smoke by an arrangement of firebrick flues and inlets, by which the products of combustion are ignited before escaping. The other excellent exhibits of this firm were noticed in our last issue.

Rosser and Russell, besides exhibiting the "Reversible Grate" we mentioned last week, are the manufacturers of several warming and ventilating apparatuses. We refer, among others, to the "Improved Low-Temperature Air Warmer," to prevent the over-heating of the air common to hot-air stoves. By this apparatus a large body of air is warmed to a moderate temperature. The apparatus is square on plan, slightly inclined at the top, with a pyramidal ribbed top. Similar ribs also surround the case, and are intended

to increase the heating surface. The stove is set in brickwork, cold-air being admitted below. The smoke is made to descend between the inner and outer cases, and gradually to give up all its heat before being allowed to escape, and the exposed surfaces are said to be over 400ft. R. W. Crossthwaite, Queen Victoria-street, have on view "Armstead's stove," a slow-combustion arrangement with double the heating power of ordinary stoves. The heat rising, instead of going directly into the chimney in a hot state and being wasted, passes round a flue at the top of stove, which has a radiating surface equal to that of the body of stove itself. Any kind of fuel may be burnt. The "Clibanus" cylinders for coppers is to effect a similar retention and saving of heat, the heat and smoke being made to travel twice round the copper before it is discharged.

Among other heating appliances we may note the "ventilating fireplace," made by Yates, Haywood and Co., Upper Thames-street, in a variety of shapes, as designed by Captain Galton, which is well known to our readers; the "Kensington" smoke-consuming grate, made by Steel and Garland, by which the gases and smoke are conducted through the fuel into a bottom chamber, where they mix with air from without, and are partially consumed, besides giving out heat to the room; Brown and Green's "Smoke-Consuming Kitchener," by which the fuel is pushed in at the bottom of grate, the "Luton," and other smoke-consuming appliances. J. McMillan's patent "under-grate coaling apparatus" for kitchen grates, to be seen in action; Strode and Co.'s sanitary stove, which "lights, heats, and ventilates," an apparatus of a tall cylindrical shape, &c.

In the east lobby, F. Lönholdt, architect, Frankfort-on-Main, shows some well-constructed anthracite stoves, adapted for warming and ventilating rooms and halls, and the same inventor has a large model of an apparatus showing a system of ventilation which will repay attention. J. Baker, Euston-square, is exhibitor of a registered stove for prevention of smoke, and J. Beardmore, architect, Stoke-upon-Trent, has a design for an open coal firegrate with pipes for warming bedrooms. Another grate (a Boyd and Son) has the heating surface increased by the iron body being made of zig-zag form, and the fire projecting. Cold air is admitted below. J. Deard's "Champion" boiler is constructed on the coil principle, and has a large heating surface.

J. E. Ellison, of Leeds, is the exhibitor of the "Radiator" ventilating valve, by which air can be admitted through any wall without draught. It is a square flat disc or front, made movable, with four cross-shaped compartments, into which the air enters, and is admitted in gently spreading currents in four directions. The Radiator can be easily fixed, and is capable of being adjusted by pulling out or closing the front disc. Ewart and Son have on view, in the eastern arcade, a ventilator for the cure of smoky chimneys, called the "Empress," by which a strong up-current is maintained. Some of these have an Archimedean screw. We must also mention C. R. Stevens's steam and hot-air heater as a simple appliance easily fitted for warming rooms, and the same firm's patent circulating hot-water apparatus is an inexpensive method of supplying hot-water to any part of the house. Herbert Lea, builder, Warwick-street, W., is another inventor of a "smokeless" grate, called the "Sunderland," the action of which is very simple.

In section D there will be found much to interest and instruct the engineer and scientific visitor. This section of the exhibition is devoted chiefly to gas-engines, boiler-furnaces, and to a variety of inventions for the

purpose of economising fuel, and abating smoke for steam-engines. There are a number of mechanical stokers, more or less ingenious, but chiefly modifications of well-known contrivances, such as Juke's. The difficulty has chiefly been to regulate the supply of air necessary for perfect combustion, and to dispose the fuel on the bars in such a manner that the volatile products may be brought in contact with hot air. G. Sinclair, of Leith, in his "self-acting stoker," claims to have succeeded in thoroughly consuming the gases before leaving the furnace, all the air passing through the grate-bars. The firegrate moves backwards and forwards, and there is a feeding hopper in front. The stoker is well adapted for the purpose, and simple in construction. W. A. Martin and Co., of Blackfriars-road, show their patent smoke-preventing doors and furnace grates; the former are balanced and remain in any position, and the merit of the invention is that they allow the air to enter at a low point, and mix with the volatile products, thus saving smoke, and helping combustion. We can also speak in praise of Chubb and Co's. (New Bridge-street, Blackfriars) very simple and economical smoke-consumer and fuel-saving apparatus, which consists of a bridge readily applied to any boiler, and a small front-damper to regulate the air. The object is to secure a proper admixture of atmospheric air and oxygen with the carbon of fuel in a state sufficiently heated to insure complete combustion. The oxygen is admitted under deep fire-bars, and becoming heated, combines with the carbon and becomes flame at the bridge. In its application to bituminous coal, the bridge is undoubtedly a means of a considerable saving in fuel. We must also mention briefly Jucke's patent smoke-consuming apparatus, and Smith's mechanical stoker, shown by G. Waller and Co., Southwark; Hunter and Co.'s smoke-consumer; Michel Perret's "multiple stage furnace," a clever contrivance for burning small dusty fuel, consisting of a number of arched fire-clay stages, round which the heated air passes, well adapted for heating buildings, hothouses; McMillan's fuel-feeding apparatus; J. Moore's appliances for Cornish boilers, consisting of a series of firebrick diaphragms; Livet's improvements; Newton's mechanical stoker; Hall's furnace-grate bars, which revolve; George Green's patent water hearth for boilers; and other means for preventing clinkering and regulating combustion in boiler furnaces. The improved fuel economiser for steam-boilers and the spiral scraper shown by Duncan Bros. is worth the notice of engineers; also the "fossil meal" isolating tubes, which are filled with silicious earth, and the fossil meal composition (A. Haacke and Co., Lime-street) are valuable appliances for covering boilers, pipes, cisterns, and tanks. A covering an inch thick of the composition renders a boiler in action simply warm to the hands, and the saving in preventing radiation and loss of heat is sufficient to recommend it to the notice of all engineers and architects. We must also mention the tubular boilers and admirable coil fire-grates of R. Renton Gibbs, and Henderson's fire-door, as exhibits of interest. There are other special features of interest in the exhibition, upon which, if space permitted, we might dwell; but we have described enough to show the number and variety of the contrivances which have been brought together to assist the committee and the public in the solution of the important question of smoke abatement. With regard to domestic firegrates and stoves, the object has been sought to be attained, as we have seen, by a variety of ingenious expedients, which may be roughly summarised into attempts to supply the fresh fuel either below, at the back, or at the sides of the grate, so as to insure more complete

combustion of the products; grates in which the fuel is ignited in the ordinary way, but which have means of drawing the smoke through the fire, or of distilling the gases near or at the mouth of the fire-chamber; grates in which baffles are used; and lastly, grates for burning anthracite or other smokeless fuel. Many of them are ingenious contrivances, and some effect the object to a degree which must be assuring to the public. Few of these grates or stoves can, or profess to, get rid of smoke entirely—this is almost impossible; but many of those we have seen effect a saving of fuel of at least 50 per cent. if not more, and so nearly attain the object of perfect combustion as to save at least a considerable amount of smoke. It should not be forgotten that simplicity of construction and management lies at the very root of success. No law can compel the ordinary householder to use a complicated apparatus which requires attention, and we hope the official examiners of the merits of this competition of skill, will not disregard the very important bearing of this point on the solution of the problem the committee have undertaken in the interests of the public.

SOME NOTES ON FLOORING-BOARDS.

IN the "good old times," and before the general introduction of steam-power planing machines, there did not exist any more exhausting labour than that which was then commonly known as "thrashing" or "flogging" flooring-boards. The work had, of course, to be done entirely by hand-labour, and it was usually undertaken by gangs of men who were neither remarkable for sobriety nor for any other of the qualities supposed to be possessed by good workmen. The words "thrashing" and "flogging" had relation to the severity of the labour, and the work was always avoided by good workmen, as being of a character somewhat lessening to their dignity. At the time of which we are writing, old contractors of the present day will be able to bear evidence to the importance which was attached in their younger days to the getting out of hand the work of preparing the flooring-boards required in a newly commenced contract. In the matter of preparing flooring-boards times have happily changed much since then, and whilst some quarter of a century ago square-jointed or square-edged flooring-boards were, for economical reasons, generally employed, to the exclusion of tongued-and-grooved boards, there need not now exist any difficulty of selection on the score of their relative cost.

There is a fashion in the style of the joints of flooring-boards which is peculiar to counties; Lancashire, for instance, employing generally square-edged, and Yorkshire tongued-and-grooved boards. It is quite certain, however, that the use of square-edged boards is fast dying out, and another decade will probably find the practice an obsolete one. There is practically no reason for its retention now that the cost of the two forms of manufacture have become so exactly, or nearly, equalised by the introduction of the steam-power planing machines.

It may be the case that in making the joint rather more wood is wasted upon tongues and grooves than upon the square edges, but the loss experienced in the former kind of manufacture is, after all, insignificant. It may possibly be, as a general thing, there is wasted, say, 1-16th of an inch, or in effect one per cent. of the cost of the prepared boards. The extra labour necessitated in the laying down of tongued-and-grooved boards over that required for the square-edged may be reckoned at about 10 or 15 per cent. of the labour charge, and for this additional outlay there is a secured a dust- and water-proof

floor, a condition which square-edged boards do not supply.

It is a more important consideration as a point of economy, when we come to consider the width of flooring-boards. For high-class work narrow boards will always be employed, solely on account of the security they afford of a close-fitting joint. But the bulk of the building work of the country is not high-class. On the contrary, economy, as a rule, is a most important consideration. Narrow flooring-boards are not economical to use. It is frequently the case that flooring-boards five inches wide can be purchased at a reduction of 15 per cent. off the price of boards seven inches wide; but the saving is entirely lost by reason of the increased number of joints in narrow boards, the extra cost of laying them, and the additional weight of nails required for the purpose. Taking all things into consideration, it is highly probable that a floor constructed of seven-inch boards costs, on the whole, about 10 per cent. less than one made of boards five inches wide. Inasmuch as flooring-boards seven inches wide will not, if properly seasoned, shrink after they are laid more than from 1-32nd to 1-16th of an inch, they do very well for ordinary house-building, and on the score of economy they are to be recommended.

Passing over parquetry-oak or other descriptions of fancy flooring, which are not within the limits set out for discussion in this paper, we have before us for consideration three kinds of wood ordinarily employed for flooring purposes—viz., redwood, whitewood, and pitch-pine. For public work and for all floors exposed to much wear and tear, and intended to be left unprotected by carpet or other covering, pitch-pine is, by reason of its hardness and toughness, a highly suitable wood. When, however, it is used it should at all times be laid down in narrow widths. Pitch-pine boards should never at any time exceed five inches wide; and they may be used three or four inches wide with advantage. Of course, a floor constructed of such narrow boards becomes expensive, but it is useless putting in pitch-pine in other than narrow widths on account of the wood being of a nature so difficult to season. We are not advocates for redwood boards of common quality; we are of opinion that where economy is to be studied it is better to employ Russian or Swedish whitewood rather than common redwood, which is not only at all times sappy in nature, but the knots of which are usually more or less decayed. Good redwood flooring takes position as a useful substitute for pitch-pine boards when the cost of the latter kind is considered to be too high. For instance, they are useful for the floors of shops and other business premises where a covering of carpet is not used. For ordinary house building, whitewood boards do excellently well. Our preference is for the Riga Crown whitewood. These boards come forward in long lengths, and there is both economy and advantage in the employment of flooring-boards in long lengths. In addition to this they are somewhat freer from knots than most of the Swedish boards, and when washed they present a very clean appearance. The boards also come forward in useful widths. For Norwegian manufactured flooring-boards we have no great liking. To begin with, the wood is not "well grown," and therefore it is not of a lasting nature. In addition to that drawback it not unfrequently occurs that Norwegian planed boards require to be "eased" at the tongues before they can be laid. The lengths, too, are often of short average, and when this is so it is a serious disadvantage. It may here be reiterated that economy in flooring-boards is to be greatly consulted by using only long lengths and broad widths.

The process of seasoning flooring-boards is an important one and requires attention.

The practice, fast becoming general, of piling the boards to season in triangular form is much to be condemned. Boards piled in this manner give little opportunity for the moisture to drip away, and when the lengths are long it frequently happens that they warp and then the difficulty of connecting the joints is a serious one. The only proper way of seasoning flooring-boards is by rearing them on an end, in which position in an exposed situation they will in ordinary weather season perfectly in two or three months, and even in less time. When boards—stacked on end—are intended to be kept in stock for a length of time, it is a good plan to rear them in pairs—i.e., two boards together, taking care that the face sides are placed together. In this manner the boards season well, and there is this additional advantage—that the face sides keep perfectly clean for any reasonable period. H. S.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE third ordinary meeting for the present session was held on Monday evening, Professor T. Hayter Lewis, V.P., in the chair.

NATIVE BUILDING ON THE GOLD COAST.

Major BALE read a paper upon this subject, in which he gave his experiences on the West Coast of Africa from 1866 to the present time. Both on the coast line and far into the interior, the natives used the materials close at hand for their constructions, and there was a general agreement in their appearance. Near Cape Coast Castle, where drinking water was not to be obtained except by saving the rainfall, the dwellings all had flat roofs, but at Elmina the houses were thatched with palm leaves or branches of long grass. In the interior of the country the "crooms"—ornative villages were generally placed near a stream. Where thatch was preferred, and yet it was necessary to save the rain-water, the natives provided a gutter round the outside walls of a house. These gutters were of fine clay, laid to a sufficient fall and well puddled; the material became hard in the sun and was rubbed by hand till it was polished and smooth in the channel surface, when, with slight repairs, it would last through the rain of a season. The natural mud or clay was used for walls, with poles cut from the forest for floor and ceiling joists, which were used without any form of wall plate. Over the joists brushwood was laid which was covered with mud rendered smooth by rubbing. This formed either the floor of an upper story or a roof, for often the bamboo rain-water shoots were put through this upper surface, and the wall at the corners and the lower room formed the house, until the occupant found it desirable to raise another story in the same way. At Cape Coast, the soil, which was a ferruginous clay, was dug out for building purposes, picked free from large stones by hand and kneaded with water into puddle called "awish," which was made up on the ground by female labour into balls of about 14lb. weight. The actual builders were men who received from the women the swish-balls, and placed them with a jerk on the wall, rudely squaring the mass with their fingers. No scaffolding was used other than a timber ladder. The sun soon dried the wall hard, and all cracks were puttied up with swish. The material was not uniform in tone, and was often much discoloured with surface dirt. The floor-joists and other timbers often projected from the walls. Boards were inserted into the walls to form the frames to window openings, and the interior partitions were of boards and mud, and were carried up through the roof, which was also divided into sections. These constructions, although very rude in character, were often strikingly well planned to suit the native requirements, were fairly proportioned, and in elevation had even an effect of dignity and repose. Some of the older houses had details such as cornices, door and window openings, worked in small black burned bricks, each about 6in. by 3in. by 2in. These were stuck together with swish but in the better-class houses, lime made from burnt shells was used, and gave a durable result. Lately the natives had copied the European use

of corrugated iron imported from England, but the structures soon gave signs of decay. It was, the author thought, a remarkable coincidence that in the older examples of these huts, found far from modern civilisation, the appearance both in plan and elevation was identical with the buildings of ancient Egypt, both being built of swish, and the author entered at length into the possibility of communication between Western Africa and Egypt, either by caravans across the interior or by Phœnician or Carthaginian trading vessels. Passing on to consider the possibility of civilising the natives, Major Bale said the case was not altogether hopeless; the inhabitants showed quick imitative faculties, but no original powers of invention, but he thought that under European guidance they might be trained to higher work and a better condition of life.

THE LATE MAJOR MANT, R.E.

A short memoir of this recently deceased gentleman was read by Mr. R. PHENE SPIERS, and around the walls were hung a very large number of drawings illustrative of his principal works. We published an obituary notice of Major Mant, in the BUILDING NEWS for Sept. 30th last (p. 440), and on Oct. 23rd gave a double-page perspective illustration, with ground-plan, of his chief work—the Lukshmi Vilas Palace, now in course of erection for the Guicowar of Baroda. Mr. Spiers remarked that the subject of his paper entered the service of the Royal Engineers in 1859, at about 19 years of age, and went to India ten years afterwards; he rose through all the stages till he became, in 1874, Major. He early showed a taste for architecture, but the first important building which he carried out was Italian-Gothic in character; this was the High School at Surat, erected in 1869-71, at a cost of £25,000. Afterwards he saw the unsuitability of Gothic for India, and turned his attention to the indigenous styles, becoming very proficient in Hindu-Saracenic varieties in which all his later buildings were erected. Well acquainted with several of the native dialects, he was able to make large use of the assistance of native draughtsmen, whom he was able, to some extent, to inspire with his own spirit. In the buildings he carried out, the plans and elevations were his own, but the decorative details were worked out by Hindu assistants. His work was seen to be characterised by so much ability that he obtained an extensive practice. He was so fortunate as to attract the attention of Sir Richard Temple, and followed that gentleman when he was transferred, in 1877, from the Governorship of Bengal to Bombay; and till the time of his death held the appointment of Architectural Executive Engineer for the Bombay Presidency, besides that of Consulting Architect to several native States. Among his chief works are the High School at Kolhapur, and a monument at Florence to the Rajah of Kolhapur; Northbrook Hall, Dacca; the School of Art and a bridge at Baroda; Mayo College, Ajmere; the Hospital and Library at Baroda; and the Hospital, Kolhapur. His three most important works were the Palace at Lukshmi Vilas, Baroda; that at Kolhapur, both now in progress; and that at Kooshehar, Bengal Presidency, of which one wing was commenced when the work was stopped for want of funds. The circumstances of Major Mant's death by his own hand were misstated at the inquest. It was not correct, as then alleged, that he put an end to his life in consequence of the failure of his plans in India. He had unfortunately, when in India, invested his money in several speculations, some of which, after his return to England, had proved unfavourable, and occasioned him great anxiety. Just at this time, the failure of a tower in India, for which he was in no way responsible, led him to re-examine his own plans then in course of execution, lest a similar accident should occur in his practice. He found it desirable to strengthen, at the estimated cost of £1,000, his foundations at the Guicowar of Baroda's palace, in a portion which was then about 5ft. or 6ft. above ground, and accordingly sent out fresh instructions to that effect. As the total cost of the palace would exceed £200,000 this could not be considered a grave defect, but this and a heavy pecuniary loss unhinged his mind. It was, added Mr. Spiers, but nine years since Major Mant's first building was erected, and since then he

had carried out, or had commenced, works the cost of which would exceed three-quarters of a million sterling. He was perfectly trustworthy in all his personal and professional relations, and his anxieties were for his friends, clients, and patrons. Had he but lived another year all his losses would probably have been recouped.

Major MORANT, R.E., thanked Mr. Spiers for his notice of a lamented brother officer, which, although generous, was not too highly coloured. Those of Major Mant's works which he had seen at Kolhapur were very successful, and marked by great taste. The indigenous styles were undoubtedly better suited to meet the requirements of India than the Gothic, in which Major Mant had first worked. He had found it necessary to remove from his designs some of the extremely lavish ornament indulged in by the Hindu, and the result had been satisfactory. The conditions of working were very different in India to those which prevailed at home. There the architect had not only to prepare the designs, but to make his own bricks, procure his own materials, and, in fact, to act as his own contractor instead of simply superintending the work. There was at present a great opening for English architects in India.

Sir RICHARD TEMPLE said he could bear testimony to Major Mant's qualifications as an accomplished architect as well as to his qualities as a man and as an officer. A more talented and conscientious man never, he believed, existed in India. His career formed an important episode in the history of that country, for till his time the English had for a century been erecting public buildings which were plain, ugly, and positively debasing in their effect on public taste. At last, the British Government were erecting buildings more worthy of them, and of late years several talented architects have been at work in each of the three presidential capitals. The loss of Major Mant would be, however, one which, if not irreparable, was at least difficult to replace. He was a born genius, brought up as a military man with none of the advantages which English architects enjoyed. His distinguishing merit was, he endeavoured to use some style indigenous to the soil, with the scientific refinements to be found in European styles, and that he abandoned the practice of Gothic, which could but appear as an unhappy exotic, for a combination of native modes of working which he called Hindu-Saracenic. Towards the end of his life—a too short life—he was beginning to frame designs which combined the resources of European science with the beauties of native art. He had, in the speaker's opinion, a few defects which frequently formed the subject of conversation between them. There was, perhaps, some want of simplicity: the work was overlaid with details, and, as he often mentioned, there was a want of some crowning feature which should distinguish the design, and be an easily-recognised point in the completed building. Returning to the subject of Indian architecture, he ventured to express the belief that members of that Institute could hardly do better than visit India, for there they would see buildings of extraordinary interest. He did not alone refer to the Hindu and Buddhist edifices, but to Mahomedan ones also, and especially to the marble structures at Agra, erected by the Great Mogul, before the exceeding beauties of which all Mediæval structures paled their ineffectual fires.

Col. Sir ANDREW CLARKE (for many years Minister of Public Works in India) said he must explain that the late Major Mant, like many other engineers and architects, frequently had the wings of his genius clipped by the official scissors of the right hon. gentleman who had just sat down. The "central distinguishing feature," which ought, according to Sir Richard Temple, to be conspicuous in every design, was seriously cut down in the elevations of many buildings on the ground of expense, and, notably, in the Mayo College, Ajmere, although that particular instance was not due to Sir Richard. He added a tribute to the memory of the late Major Mant, remarking that amongst the able men still left was Captain De Fabeck and a young and promising man, Captain Cole, the son of Sir Henry Cole, of South Kensington. He agreed with the last speaker that the time was very far distant when we should be able to rely on native architects in India. Europeans were needed as administrators and directors, and, indeed, around the beautiful buildings at Agra might be seen the

tombs of the Italian architects, to whom, he believed, the conception of those beautiful structures in white marble was really due.

Sir JOSEPH PHAYRE spoke in high terms of Major Mant's works in Baroda, and added that experience showed Gothic building to be most insupportable and unsuitable for India.

The CHAIRMAN remarked that it was a question whether we were not justified in introducing the Gothic style into India, and whether, therefore, Major Mant followed the best course in adopting the indigenous modes of building. If we refused to take our style with us, it would be the only instance in history, with the notable exception of Egypt, where a conquering nation had not imposed on the vanquished one its own architecture, as well as its arts, laws, customs, and language. Furthermore, it was now possible, in going into India, to give the exact date of a building and its history from its architectural features; but this would be impossible if we copied the Indian styles of building.

THE NEW COMPULSORY ARCHITECTURAL EXAMINATION, AND WHAT IT INVOLVES.*

(Concluded from page 719.)

NOW that we have gained some idea of the object which the examination may be understood as proposing to itself, and of the general course it is to take, the question still has to be answered, How will it turn out? A great deal depends upon the examining body. This consists of a board of not less than five, or more than 12, Fellows of the Institute. The names of the members of the first board are as follows: The President, Mr. Street, R.A.; the three Vice-Presidents, Mr. Hayter Lewis (Emeritus Professor), Mr. Horace Jones, and Mr. Ewan Christian; the Honorary Secretary, Mr. Macvicar Anderson; and Messrs. James Brooks, Arthur Cates, E. A. Grüning, E. H. Martineau, E. R. Robson, Alfred Waterhouse, A.R.A., and T. H. Watson. This board will, no doubt, feel bound to carry out the statement in the published programme: "It is intended that at first the test shall not be severe." The examiners under the Building Act form a board of very similar constitution, and no doubt the useful work done by that board has influenced the decision to extend the present examination to a similar body. There will be some little difficulty in keeping the standard uniform, and there may be some trouble at first in getting so large a board into working order; but I am inclined to believe that a tolerably numerous examining body like this offers a safeguard to students against violent fluctuations. If from year to year new men are elected to replace the retiring members, still the majority of the board will remain from one examination to another; traditions will, to a certain extent, establish themselves; and, in all probability, a tolerably uniform standard and mode of procedure will be preserved. The first examinations will be looked forward to with great interest; and to pass on one of the early occasions will, no doubt, reflect credit, and even distinction, on those who do so. Very many gentlemen who might, one would have thought, have been sure of success have preferred to enter on the old principle, but some of them will, I believe, come to regret that they had not more confidence in their own powers. It would perhaps be a wise thing, if for two or three years the examination was, so to speak, made retrospective, that is to say, thrown open to gentlemen already Associates, so that some of those now in the body might have the opportunity of adding what will no doubt be a real distinction to their names.

Of all the things which may be involved in the new examination, nothing is so self-evident as that it must be prepared for, and that this Association possesses the means of aiding in that preparation to a very large extent. Three sorts of preparation may be very easily recognised, as all useful, in fact necessary. First that practical acquisition of professional knowledge, and the power to make plans and prospectuses which is gained in an office and on the works, in practice on one's own account, or as an assistant or pupil. No one must hope to pass such an examining body as that Board at Conduit-street unless he has had sufficient practical training to

enable him to do all the routine work of an architect's business, and some at least of the exceptional work. No one could, I imagine, go up from college, or classes, or any sort of instruction 'that is purely theoretical, and hope to succeed, any more than a medical student could pass his examination without having walked the hospital; and it will hardly be easy for those who have never done any work on their own responsibility to master this, the practitioner's, side of the qualifications sufficiently for success. Secondly, there is theoretical knowledge of materials and construction, of history, and of what one may call the theoretical drawing, so far as the details of one style goes. This must, equally with practical routine, be mastered, and for the acquisition of this pupillage and practice, neither of them, supply much opportunity. Classes and lectures, and private study must be used with the view of learning theory. Thirdly, and by no means of least importance, there is practice in answering papers of questions, and in replying to a *circa-voce* examination—in short, the skill to use the knowledge acquired. I propose to say something on each of these three heads. First as to what we have termed the routine of Practice. The greater number of those who are likely to desire to become Associates are probably more likely to be familiar with this than to be quite safe in either of the other two branches of preparation. Sharing for some years in actual work, or the carrying out a single building of one's own, will give good opportunities for becoming familiar with an architect's work; and the only hint, perhaps, that need be given, is to suggest to gentlemen who are pupils and assistants the importance of keeping their attention awake to all that goes on within their reach. The practical subjects which are most accessible to one man will be least so to another; but, on the whole, dealing with ruinous and dangerous structures, and planning for special purposes, appear to be the two most likely to lie a little wide of the range of many architects' pupils. As to the ruinous structures, they, as I have already hinted, occur from time to time, and if a young man is on the look out for information, he may be able to learn a good deal even from a single case of this sort. As to designing, that is mainly learnt by practice. Any one can exercise himself in planning if he pleases, especially now that so many prizes are open for such work. But on this part of preparation, let me point out that the recent formation of a class for the study of planning and specification writing, and the two classes of construction and practice, ought to aid members of the Association very materially in their acquisition and systematising of what may be termed practical knowledge. Perhaps it would be right to add the hint that some acquaintance with iron construction, will, probably, be expected now that we have fairly entered the last quarter of the 19th century. The candidate at such an examination ought, at least, to be prepared to sketch iron beams correctly, and calculate their sections, in addition to being familiar with timber, brick, and stone construction. The second part of my suggestions as to preparation for the examination refers to Theoretical Knowledge. Here, I think, there is room for a great deal of improvement in our methods of instruction, and I venture, even at the risk of giving offence, to say that much of our modern architecture has suffered in consequence of defects in this instruction. Probably the greatest service which the examinations can possibly render will be the causing many pupils and others to learn something of the history of our art, and to acquaint themselves minutely with a little bit, at any rate, of that art. My own profound impression is that a good, familiar knowledge of some of these things is of the greatest possible value of the architect, and that the question, whether he shall rise or not in his profession, depends upon his mastering a few things which he does not see are likely to be immediately useful, such for example as drawing the human figure, in addition to the things of which he has need at the moment. But many of the younger among us do not seem deeply penetrated with this idea, and for them it will, as I have hinted in an earlier part of the paper, turn out to be a great advantage, that now something has arisen which will compel a little attention to theory, and art history, and architectural study of the higher kind. This, however, is a digression; the immediate subject before us is to find out how history, and the

science of construction must be studied, and your committee has, very wisely, as I, at least, who am myself an instructor, must admit, determined that some direct instruction shall be afforded here in these subjects. You are, of course, all of you, aware that two courses of lectures, one of which is to be a kind of companion to the subjects in the elementary class of design, and the other similarly to accompany the subjects in the elementary class of construction are arranged, and, indeed, have already begun with every promise of success. I do not think these subjects could have been entrusted to better hands than those of Mr. Tarver and Mr. Blashill respectively, and the only thing to be regretted, is that it was not possible to make each course longer. Still as the lectures are delivered at considerable intervals of time, as they are associated with the subjects for study in the two classes, and as it will be possible for you, if you are industrious, to carry your study of each subject further than Mr. Blashill or Mr. Tarver can, within the space of an hour's lecture, take you, these courses may enable you to acquire a very considerable amount of knowledge respecting the subjects treated of. Mr. Tarver's series includes, after his introductory lecture, all those styles (or at least the most prominent of them) which combine to connect the work of the present day with that of the most artistic nation on the face of the earth. The Greeks fixed for all time a very large part of the architecture of civilised communities. Not that we, or those who went before us, are wise if we attempt to build in Greek, but that each style has been founded on the one which preceded it, and all alike inherit, from Greek originals most of their features. The Roman we all know was a coarse rendering of Greek art with the addition of the arch. The Romanesque, Byzantine, Lombard, and Rhenish are all children of Rome. The Gothic styles are their immediate descendants, and the Renaissance, the last in the series of Mr. Tarver's subjects, is a return to Roman forms animated by a modern spirit. This is the tale of Architectural History, as it affects ourselves, told in a sentence, and I sincerely hope you will all hear it told far more completely in Mr. Tarver's class. Not less comprehensive is the scheme of Mr. Blashill's constructive lectures. The first two relate to the foundations and walls of a fabric, the subjects being excavator, bricklayer, and mason. The next two relate to the completion of its carcass, namely the work of the carpenter and the tiler, and they take in that of the plasterer. The remaining four take in the most important parts of the finishing of a building, joiner and ironmonger, smith, plumber, painter, and glazier. Under the plumber you may be sure that you will, from Mr. Blashill, not only get some advice as to the construction of flues and gutters and so forth, but an account of those methods to which I have already had occasion to make allusion, that modern skill has brought to bear on the sanitary condition of dwelling-houses. The plumber has heavy responsibilities upon him: not only has he in times past set fire to many a cathedral spire and roof, but in our own days his shortcomings have been followed by disease and fatality. How to deal properly with plumber's work, means really the management of water supply, of drainage, and of sanitary fittings; in short, the protection of the inmates of a dwelling from sewer-gas. Perhaps it may not be out of place if I add the suggestion to members able to attend these courses of lectures that they will be wise to take the opportunity this session and not to postpone their attendance till another. The courses may possibly not be repeated, or if repeated, they may be in a different mould. The opportunity is presented now, and is a very valuable one, and no one will regret the very moderate fee, and the very moderate sacrifice of time which attendance on both these series of lectures would involve—and even though one in the Construction course, and two in the Art course are already given, that circumstance will not permit attendance upon which the remainder from being most desirable. The third point to which I drew attention was Practice in Examinations. It is possibly a weak point in the Architectural Association system that there is not a system of examinations connected with it. The experience of University College shows conclusively that the examination at the end of the session acts as a stimulus, and also helps the student to gain a command over his own

* A paper read before the Architectural Association by Professor T. ROGER SMITH, on Nov. 25, 1881. (See p. 717.)

resources and his own equipment. And though I feel that I am more fortunate than my two friends just named, not only in having to treat substantially the same series of subjects in three times as many lectures, but also in having an examination and competition prizes to point to, I cannot but see that the Association, if it chose, might do more than it is easy for University teachers to attempt in the way of examination-practice, if I may use the word. No one can do full justice to what he knows in an examination whether by pen or at all, unless he be somewhat in the habit of answering questions—and answering them, so to speak, under pressure. The members of your new History Class, and those of the Construction Class will probably both of them have an opportunity of attending an examination, or perhaps more than one, and they will be wise, if they all avail themselves of that opportunity when it comes, and prepare for it well beforehand. In addition to this, however, some arrangement to afford practice in answering an examination paper on architectural subjects, within a certain limit of time, and without recourse to books of reference, it could be made, would be very serviceable for their education, as tending to give them confidence, and to show to them, where their weak points are, in time to apply a remedy. Such an arrangement would be quite practicable here, and would surely be worth attempting. One measure which has been from time to time strongly advocated in this Association, is certainly closely allied to the new examination, but is not involved in it. I allude to a diploma for architects. The two things resemble one another so much that we are apt to forget how widely they differ. It is not unlikely—at any rate not impossible—that the new examination may be found to afford the chief advantages of a diploma without some of its obvious disadvantages. Take, for example, the difficulty of deciding what is, and what is not, to be prohibited if a diploma is granted. The only art which could well be taken hold of as conferring for advantages or payments to a builder, and this, it is obvious, has to be done by engineers, naval architects, and many other classes of practitioners, so that a prohibition could be readily evaded. But if the result of the examination is to establish publicly that the Associates of the Institute are a body of architects in whom the public can place confidence, it may very possibly turn out that Associateship will be sought by every architect of skill sufficient to pass the examination, and will be accepted by the public as equivalent to a diploma. It may, on the other hand, very possibly pave the way for the grant of such a document. At any rate, what we have to consider to-night is not the diploma question, but the examination question. If once we recognise that, quite apart from any other measures or ulterior consequences, the examination ought to result in raising the status of architects, in procuring a better estimation of them by the public, and in rendering them more really deserving of public confidence, we surely must recognise something which we are glad to see established, and which we feel ourselves bound to support, by promoting the candidature of the best men in the Association, and by assisting them in the preparation. It must not be forgotten, in conclusion, that, like every untried measure or new departure, this examination is an experiment, and may fail. One serious, or at least possible, risk of failure seems to lie in the fact that so many young men have avoided the examination by becoming Associates under the old rule. The result may very possibly be that fewer candidates will, at first, be forthcoming than there ought to be; but I have every confidence that even if this is so, the Institute will persevere, and that the confidence of young architects will make them come forward in sufficient numbers. There can, in that case, be no doubt of success. Were the examinations to fail, the failure would then run back 24 years, perhaps 25 years. On the other hand, if they succeed, we shall see established in our midst what ought, under good management, to prove a powerful agency for good. The consequences ought to be far-reaching and greater still. The architect's title, for his work ought to be at once more assured and better recognised. The general estimation in which our profession is held by the public ought to be proportionally raised. Let us all, each one as he can, endeavour to contribute to this result.

IMPROVED METHOD OF WARMING FRESH AIR.

Messrs. Robert Boyle and Son, ventilating engineers, of 64, H. D. B. road, are the inventors of a simple and ingenious arrangement for warming the supply of fresh air admitted into rooms and public buildings. It consists of a miniature coil of pipe placed in the top part of a vertical tube, as shown in diagram No. 1. A is the top of tube.

made of iron or zinc to render it fireproof; B, the coil; C, an air-burner; D, shield perforated at bottom to prevent the current of air passing up the tube affecting the flame; E, the pipe to

carry off the products of combustion; F, three-eighths gas-pipe led from the most convenient source to supply air-burner; G, shows gas-pipe brought down from a bracket. Diagram No. 2: H, regulating valve in tube; J, air-hole cut through wall; K, cast-iron grate; L, mouth of pipe for carrying off the products of combustion; dimensions of air-tube 20in. by 9in. and 42in. It has been a long-felt want, some simple and effective means of warming the air admitted

into rooms, and the appliance above described will, no doubt, be hailed as a practical solution of what has hitherto been considered a very difficult problem in ventilation. This plan has also the advantage of being economical, and with it in conjunction with the air-pump ventilator, Messrs. Boyle guarantee the satisfactory ventilation of any building without the slightest disagreeable draught being experienced.

PRACTICAL NOTES ON PLUMBING.—XXI.*

By P. J. DAVIES, H.M.A.S.P., &c.

CLOSET TRAP EXPERIMENTS.

(Continued from page 657.)

I AM now in a position to explain the true working of traps, having for the last 20 years, made them one of my especial hydraulic studies, and on Monday fortnight, by experiments made before several disinterested gentlemen, I was convinced that my ideas as to the merits of the various traps have been at least in the main correct, and as I am not in any way interested in the manufacture of traps, I take it that credence may be given to my opinions. It may be remembered by the readers of this Journal that at one of the lectures given by Mr. Hellyer at the Society of Arts rooms, I proceeded to explain the faults of the U-trap, and met with various interruptions, amongst which were remarks from Mr. Hellyer, such as, "What are you?" "Who are you?" together with a storm of hisses, but happily only from the well-known Newcastle-street geese. Besides this, Mr. Hellyer has written to the paper, saying I am not worth smoke. Now, in vindication of my assertions, I am compelled to explain the result of these experiments, which will once more prove that in a sanitary point the half U-trap is decidedly a failure and that the C-trap possesses all the advantages I claimed for it. I shall not have occasion to refer to mathematics, nor even go so far as to require the explanation of the letter "g" in mechanics, but proceed to show clearly the simple principles that govern well and badly constructed traps respectively. Every plumber must know that during the time water is passing through a trap, there is necessarily motion. This motion is known as momentum, and the quantity of this momentum must be considered.

In the first law of motion we are taught to distinguish the meaning of the word "inertia," which is the simple resistance of matter to a change of state, whether of motion or of rest. Let us, for the purpose of this argument, turn to page 345, and examine Fig. 84.

In the bottom of the trap there shown will be seen the water, K, D, C, apparently stationary or in a state of inactivity. In the same diagram will also be noticed the water dribbling from the valve F. This dribble is not enough to engender sufficient momentum to instantly throw out the whole of the water within the trap; therefore the inertia of this water cannot be said to be acted upon, as it should be, by the incoming water from the valve F, and whenever this constraint occurs, there is a resistance brought into play which is known in mechanics as reaction, and which in this case is totally fatal to all self-cleansing traps. In this illustration and explanation you have a clear proof that the handle of the closet should be fully pulled up, in order to enable all the water to pass full bore and rapidly into the trap, so that the incident motion directed from the water in the basin shall have full power to expel the whole of the foul water contained within the trap. This applies to all traps—closet or otherwise.

The following figure represents B and Dent's 4in. Cast-lead Trap, which I have proved to be a failure for slop or valve-closets. This is all I want to do, as thousands are fixed yearly, and cause no end of trouble; of course, there are places where such traps can be used with safety, on the top of which is a valve-closet. If you pull up the handle and valve 3 of the closet, the water, like all other substances, will obey the definite law of gravitation—it will fall, with accelerated force, onward towards B S; but as the bottom of the trap is rounded, the water is easily turned out of its straight

* All rights reserved.

line of path from B to CDE, and at each successive instant will tend to fly off in due proportion to the speed. If the front, from E to F,

were cut away, it would fly off at the tangent, EPFO; but as the front of the trap impounds this water, it is again directed from the point of contact, HG, towards the tangent line, LK, when it again glides round the e-y, curved line, GJU, and flies off at the tangent, LM, as though it were a stone from a boy's sling.

Now the effect of this is, that with a closet-basin half-full of water, having a valve fixed only 6in. from the water-line in the trap, on the valve being properly opened, so as to cleanse the trap, the water will gain sufficient velocity to sweep onward; and as there is not sufficient reaction, neither by friction nor by the curved lines of the trap, the momentum of the water is unchecked, and consequently the trap left without sufficient water to prevent the air passage, as shown at X, Fig. 128 B. Now suppose this to be a pail of slops, it will have the same effect.

FIG. 128 B.

FIG. 128 B.

FIG. 128 C.

This result is palpable if you only consider the weight of the water and the curves of the trap, which may be compared to a bagatelle ball passing round the head of the table.

Now let us examine 128 G.

This is a trap to which I would have trusted

my life, until I discovered the momentum of water in traps. We are told, and it is a fact, that water will always pass onward in a straight line unless it meets with some substance to check it or divert its course. Now, suppose this trap to be fixed as shown at M, Fig. 2, page 540, having the basin C on top; three-parts fill the basin and lift the full-sized valve as shown at F 7. Fig. 3, as you would were it a valve closet; thus fill the pipe part A, Fig. 128 C. The water on falling will strike against the bottom, BC, and would fly off at the tangent line, OP, but as in the trap before referred to, it is by the very easy curve, EF, directed in the line FLT K, up against the rounded top, H, when it is redirected to the out-go. This, I think, is quite clear, and will be readily understood on reference to the dotted lines shown in my diagram between K and N, Fig. 75, page 354.

Now refer to the trap on the left-hand side of the last figure described, Fig. 128 B.

FIG. 128 D.

FIG. 128 E.

This is the complete 4in. trap; but owing to its shape is extremely unsuitable for general work, to say nothing about its being difficult to make, for instance, from outside to outside, or S to V, is 16in.; then again it is at least 10in. deep—that is from the top at G to the bottom at E, though it, of course, many years ago, has been made as Mr. Emptage suggests, with the curved out-go, Y X P, or to any other pattern. In proof of which I may here remark that these traps are excellently made to almost every conceivable shape by the patented process of Frederick Nelson Du Bois, and sold by Mr. G. Jennings, London. It should be remembered that all my drawings and writings against the trap have been in reality directed against the half trap, called a trap, generally made by Beard and Dent. The real trap has its faults, but will not momentum out like the half trap does.

MR. HELLIER'S V-TRAP.

This trap is shown at Fig. 128 E and D above.

FIG. 128 E.

It has a round pipe inlet $4\frac{1}{2}$ diameter, and stands the usual height of the trap. It has a $1\frac{1}{2}$ water-lock, and of a V shape, holding a good body of water; it is made to the proper curves with a flat top, which at a glance will, by a mechanic, show it is proof against momentum; but, like all other traps, will require to be well ventilated for more reasons than one. I cannot, however, agree with the ventilating pipe being fixed directly on the top as shown at D in the advertisement diagram. (Vide paragraph on air pipes.) The out-go of this trap requires improving, as it is to a novice rather difficult to work to.

TRAPS.

The trap, Fig. 128 E, it is easy to see, is thoroughly proof against momentum; nor if

they are made properly to prevent siphonage, will they siphon out. But so far as siphonage is concerned, if people will not ventilate properly after so many powerful arguments have been used showing its importance, the sooner they are poisoned the better it will be for those

living who will attend to ventilation. I doubt not that now you will be quite able to comprehend the action of the water in passing through the trap. It first strikes the heel at B; otherwise it would pass in the straight line to RS, but is by the band of the trap directed to E, where it would, if not for the front of the band, pass off in the tangent line, EP, but it is guided onward until it comes to the point of contact with the tangent line L; it then strikes off in a right line, and dashes up against the top, when it is reflected or thrown back against, so to speak, its own life-giving pressure, in what I may call a state of eddy confusion, when it is greatly retarded, and passes out at the out-go, M, without any sign of loss of water within the trap from momentum,—that is, when fixed under slop or valve-closets.

SLOP-THROWING THROUGH W.C.'S, &c.

Scores of times I have been called out to examine servants' slop and other closets, and have been puzzled to find out the cause of the stinks, in consequence of the trap becoming resealed before I have had time to get to the house, and on examining the traps for air-pipes, thinking it may be siphonage, I found them all right. The reason, however, is now quite plain. Let a pail of water be thrown down the w.c., pan-closet, Fig. 128, C, and the handle shut down before the trap is recharged, and you will find the stink must rise. How often is this done when there is no water even laid on, or during the time there is no water in the cistern? and again, how often in the winter-time are we obliged to flush out the closet during the time the pipes are frozen—better known as hand-flashing? All these points have to be considered before fixing the half trap.

AIR-PIPES

You can easily understand that if you fix an air-pipe in the way of the momentum-line of the water, that the water will throw up the solid matter, such as paper, &c., and very soon cause the air-pipe to become blocked up, and consequently useless. Examine I in the above Fig. 128 C, also G, Fig. 128 B. I, in this last drawing, is the proper position for the air-pipe, as close to the round joint of the out-go as possible, so as to be out of the way of the momentum, &c., but, of course, it is not required unless the length of out-go pipe is longer than shown in the Fig. 128 B.

(To be continued.)

[This article was crowded out last week, but was in type before the letters which appeared in our last from Mr. Buchan and Mr. Emptage were received.—Ed. B.N.]

TEWKESBURY ABBEY.

IN reply to a letter in *The Times*, repeating the mistake in the anonymous writer's report first sent to that paper by the Society for the Preservation of Ancient Buildings, Mr. J.

Oldrid Scott writes:—After a very accurate description of the fine west front of the Abbey, Mr. Middleton goes on to speak of the window which has jambs and arch dating from the 14th century, with a filling-in of Late tracery about which the discussion has arisen. He states that this tracery was not made, but only repaired, in 1680, and that it belongs to a genuine Perpendicular window. This I am convinced is a mistake. It is highly improbable that if a window had been inserted by the Perpendicular builders they would have retained the Decorated jambs; and, besides this, the details of the tracery are not such as are found in Perpendicular windows, but clumsy forms, such as might well have been used by the churchwarden builders of the 17th century. The tracery does not fit the ancient jambs, and in some places old little corbels have been used to get over the difference. The history of the window is known. It was blown in during a great storm in 1661. There was great difficulty in raising money for rebuilding it, only £82 having been voted at the time for this purpose. In 1661 a further sum of £120 was provided; but it was not finished till 1680, when a rate of 9d. in the pound was voted "for completing the west window and supporting the long roof." As regards the value of the tracery in question, I imagine no one not a member of the society thinks it otherwise than unsightly: it is a literal piece of "Churchwarden's Gothic," and no doubt a good example of the style. At the same time, it has a history of its own, such as it is, and is in good repair. Moreover, it has formed an important feature in the Abbey for a long while. Its treatment has never become a "practical" question with the committee; but it has, of course, been talked of from time to time, and my advice has been that, considering the lines the committee have always laid down for themselves and the extreme narrowness of their funds, the insertion of new Decorated tracery is not a work which it would be desirable for them to undertake, though it would be highly advantageous to have the window filled with good stained glass, as in this way its defects, which are seen much more inside the building than out, might be, in a great measure, removed. It is not necessary to consider what should be done if some individual were to offer to defray the cost of new tracery. At Tewkesbury the committee are relieved from the anxious responsibility of looking gift-horses in the mouth which they suffer from at St. Alban's, by the fact that no horses are ever offered; though, happily, smaller gifts are by no means unknown.

TERRA-COTTA AND FAIENCE AS MATERIALS FOR ARCHITECTURAL AND DECORATIVE APPLICATION.*

(WITH PHOTO-LITHOGRAPHIC ILLUSTRATIONS.)

(Continued from page 722.)

MUCH depends on the quality of the material and the colour desired, and very great practical and very great technical skill is required to secure even an approach to perfection. By some makers, muffled kilns are adopted, in which the flame does not come in contact with the clay; some adopt down-draught kilns, and others up-draught, some use square kilns, and some round; there is, in fact, no rule, but the rule of experience, based upon the nature of the materials and the appliances at command; but what is essential to good terra-cotta, whatever the precise mode of securing it, is that it should be thoroughly well burnt. I need not say, however, that in some cases the rule of thumb and precedent is more blindly followed than is altogether desirable, and a thoroughly intelligent perception of cause and effect upon anything like scientific data is too often the exception rather than the rule, and hence it often happens that great irregularities occur in the degree of heat applied and in colour produced. Much greater attention has of late, and is now being given to this most important subject, and, indeed, it is obvious that it is a critical point in determining the question of the more general application of terra-cotta. Badly-made and excessively-burnt terra-cotta is simply an architectural abomination, but assuming the condi-

tions to be satisfactorily solved, as they may be, I will next allude to the question of durability.

Is terra-cotta as durable as stone? I might reply in one sentence: There are all qualities of stone and all qualities of terra-cotta, and the inferior qualities of either are undeniably bad; but I believe I might go so far as to affirm that a thoroughly well-made, well-burnt block of terra-cotta is equal in constructive durability to the best stone, and probably superior. The fact that burnt clay of a good quality is almost indestructible, is proved by the remains of bricks and tablets discovered by the researches of Layard and Rawlinson amongst the ruins of Ancient Babylon, in an almost perfect state of preservation, whilst we have modern illustrations of its durability over lengthened periods in the quaint old brick structures yet met with in England and on the Continent, affording, under trying conditions of climate, valuable evidence of the durable nature of well-burnt clay.

The great test of durability is the power of resistance to severe and sudden atmospheric changes of temperature, and to the more insidious attacks of the acid gases which, in all large cities are more or less present in the atmosphere, and often work sad havoc with buildings on which the greatest care has been exercised in the choice of materials. Instances of this are too well known and numerous to need reference. The question is, Will terra-cotta be more durable than stone?

The general use of architectural terra-cotta in this country is too recent, and the dates too imperfect to afford any very striking comparative facts on this subject; but collated evidence, I think, strongly supports the presumption that well-made and well-burnt terra-cotta is much less puerile to the action of acids than stone. As far as chemical tests are of any value, they are certainly strong in support of such a proposition.

The soft silicious bricks and terra-cotta made of silicious clay, whilst they often secure a charming architectural effect, are too porous and open in their grain to withstand any severe disintegrating action. Some qualities of silicious bricks undergo a certain degree of induration by atmospheric exposure under modified conditions, but they do this by their reception of atmospheric particles, and are therefore the more readily subject to the discolouring influences of smoke in the atmosphere of large towns, very quickly becoming choked with carbon, which is a serious drawback to their general use for enriched work. The most insidious and powerful disintegrant is alternate frost and thaw, and if these operate under conditions favourable to their action disintegration is rapid. Terra-cotta half-burnt, like a soft stone, is sure to yield to such influences sooner or later; but it may safely be affirmed that no material is more likely to resist them than a thoroughly plastic clay, good quality, the constituent parts of which have been brought not into mechanical, but into chemical combination by the requisite amount of heat.

A question of the utmost importance in connection with the use of terra-cotta is its comparative cost. This is determined partly by locality, and partly by the quality of workmanship. In districts in which good stone is abundant and readily accessible, and to which terra-cotta would have to be imported from any distance, it would probably be an open question as to the comparative cost for constructive use; but this general view is subject to large modification, and is subject to the character and extent of the structure, the proportion of repetition in the details of the design, and the quantity of mouldings and enrichments. If, on the other hand, both the stone and terra-cotta have to be imported, the probabilities are very decidedly in favour of terra-cotta being the cheapest; but the general proportion of cheapness will again be determined by the conditions I have just named. The element of cheapness in terra-cotta depends primarily in the extent to which each block can be repeated. Whether few blocks or many are required, the cost of making models and moulds has first to be incurred and calculated, and if it can be distributed over a large number of blocks, the cost per cubic foot is considerably reduced. If, on the other hand, only a few blocks are required of any certain form, the cost of models and moulds must be rated against them adversely. Sometimes, however, this is not so formidable a matter as would at first appear,

and much depends upon the nature of the details, and the practical way in which the work is designed and subsequently set out. It is often possible to introduce considerable variety in some directions without any appreciable increase of cost in model-making; whilst, on the other hand, a design may embrace almost the minimum of variation, and yet involve large additional cost. On such points it is very desirable that all architects should possess, as some do, a practical acquaintance with the mode of manipulation, in order to secure the best results; or, as in alternative, that they should elicit some practical suggestions on the subject in elaborating the details of the design, or in making the working drawings. From what I have said, you will at once see that it is difficult to name any general price for which terra-cotta work can be executed per cubic foot without reference to the structure for which it is required. It varies from about 4s. per cubic foot to double that sum, according to circumstances and the nature of the details. It may even run up to a very much higher figure than this, and still be considerably cheaper than stone for the same work. The same general principles govern the comparative cost of terra-cotta in a modified form. When applied more specifically as an enrichment, it is less necessary to take the question of distance into consideration, and in many forms of enrichment it is possible to secure great variety of design, by a judicious use of existing models. There are many instances in which this can be done in complete harmony with the artistic and architectural character of the structure, and if the designs are good ones and well modelled, a little skilled adaptation will often enable an existing model to be turned to account at very much less cost than would be involved in the special preparation of a new one. If however, for important structures original modelling is required, I believe it will be found that in most cases it is decidedly cheaper than stone or brick carving of a similar character. Of course there are all degrees of modelling as there are all degrees in carving, from very good to very bad; but taking really first-class work in spirit and execution as the basis of calculation, it is safe to say that terra-cotta will cost least, even in cases in which there is little or no repetition, whilst if there is repetition the difference in cost soon becomes considerable.

The use of terra-cotta for enrichment, in the form of bands, strings, small patterns, diapers, and similar forms has stimulated the production by machinery of a number of hard cast-iron looking designs, more or less geometrical or conventional, which have found some favour by reason of their low price; but many of these things cannot be considered as good artistic work, and I, therefore, do not venture to include them in any calculation of comparative cost—they rather rank with brick-work. I have instituted no comparison between the cost of brick-work and terra-cotta, because it is obvious that brick is decidedly the cheaper form of burnt clay, and may often with great propriety and economy be judiciously used constructively in conjunction with terra-cotta, either according to the original conception of its use by the Italian revivalists, or in more modern forms.

The decorative application of terra-cotta faience is so closely allied with terra-cotta, that it will not seem out of place if I now ask your consideration for a few minutes to its special features as a decorative material. The term implies a French origin, and as you are no doubt aware, was originally applied to a glazed pottery of somewhat stronger and heavier character than ordinary pottery made at the Faience. The term is still used in France in its original signification, but has gradually been applied in a more general sense to many forms of decorative glazed ware, and has been adopted as a not unsuitable and fairly descriptive term to a material that might also be called glazed terra-cotta, had not that term been previously adopted for a material without much character, and without beauty of either form or colour to recommend it. Under the general descriptive term of *Burmantofts Architectural Faience* is included all forms of terra-cotta, constructive or decorative, for exterior work, and also many special forms of the faience now introduced and very favourably received by the profession for interior application. The material itself may be described as a ware of finer and closer grain than terra-cotta, manipulated by practically

* Paper read before the Leeds Architectural Association on Nov 24th, by Mr. JAMES HOLDSWORTH.

the same process, and brought into the desired form by an elaboration of the methods applied to high-class terra-cotta. To give it increased hardness and character it is, however, fired at a much higher heat, and being composed of very pure and clean raw material, it is capable of receiving any colour, either by the body of the material being mixed with various oxides requisite to produce the desired results, or by being covered with coloured metallic glazes with a similar object. By both these methods, adopted alternately, according to the object to be attained, a very hard, durable, and beautiful material is produced, eminently adapted for working out, in a permanent and artistic form, both the simplest and most elaborate varieties of architectural decoration.

The specimens of the material now submitted to your judgment will, I think, bear me out in these remarks, and will render it unnecessary for me to add further description. I might, however, add that in bringing these specimens before you, I do not claim for them any further novelty than they possess. They illustrate, in fact, the modern application of a process, as old or older than history, to modern designs and uses, and in a more complete and elaborate form, and this is all that can fairly be claimed for Burman's terra-cotta. It is, in fact, the modern form of the enamelled bricks of Babylon and Nineveh, of which we still possess elaborate remains, of the Italian enamelled work, in which men like Luca del Robbia excelled many centuries ago. It differs from tiles, inasmuch as it combines constructional uses as well as decorative, or can be applied simply in a decorative form, and it differs from most modern forms of tiles also in that it is manipulated on the plastic principle entirely, and is therefore much more capable of being readily applied to any desired form and to any design, by the intervention of elaborate mechanical appliances. The beauty and mellowness of the design is not lost by transference to metal, and every minute touch of the artist can be made to tell either upon a small tile, or in a large block.

The mode of its application I can safely leave in your hands and in the hands of the profession at large, to whose ready appreciation of an effort to contribute to the range and quality of architectural material, it gives me the sincerest pleasure to make respectful recognition. I may be permitted to add but one remark. The use of colour in exterior architectural design is, no doubt, a question of some difficulty. Many attempts have been made to secure satisfactory results in that line, and there have been many failures. For thoroughly harmonious effects it, unquestionably, requires the eye and skill of a thoroughly competent artist, and some practical experience of the material to be used. In England, at least, we are, probably, not prepared by our atmospheric or natural surroundings for the wealth of colour so charming and harmonious to the eye under brighter skies; but no one not an hypochondriac can, with any propriety aver that we are not open to very considerable improvement in this respect, or be unready to welcome the judicious and tasteful use of such materials as improved methods of manufacture and increased scientific skill place at the disposal of the architect and builder.

On the general question of the application of terra-cotta, may I now be permitted to make a few practical remarks? I noticed that your esteemed president, in his opening address, alluded to the objections to the use of terra-cotta, caused by its liability to shrinkage and to the twisting, &c., of lines that should be rigid caused in this way, and there can be no doubt that in these remarks he has spoken from extensive practical experience, and yet I venture to say that if he would add yet further to his experience, taking due precaution in the matter, he would require no other arguments to convince him that the qualities he ascribes to terra-cotta do not necessarily pertain to the material, and are characteristic only of a bad form of it. No doubt there are, unfortunately, notable instances of bad terra-cotta, as there are of bad materials of almost any description; but there are also some instances exactly the reverse. This much can be said for terra-cotta: that every year increases the knowledge, skill, and appliances brought to bear in its production, and as trained and skilled workmanship is brought to bear with improved processes, the quality of the work must improve in the respect in which

I am bound to say it has been, and is still, sometimes very deficient. As a material, it has too often been resorted to by architects for its supposed cheapness, and too often it has not been the best made by the best makers, but the cheapest made by the lowest-priced maker that has been adopted. By this standard terra-cotta work has been judged and found guilty, whereas there is no material in which there is greater margin for skill and superiority of treatment, or for inefficiency and failure. I hesitate to say what I have known of the miserable shifts by which terra-cotta is sometimes turned out to meet the demand of the lowest possible price as the alternative of the greatest possible excellence, and there is little wonder that such terra-cotta is unsatisfactory.

Another objection to the use of terra-cotta, and one in which I feel there has been and is still some force, is that it is slow of production. There is no doubt that it does take more time than some forms of material for its satisfactory production, and there is no doubt also that its extensive use in a structure has sometimes caused a somewhat slower erection than has been desirable either in the interests of the builder or the owner. There is no doubt also that in such an event the terra-cotta manufacturer gets the full benefit of any irritation caused by the delay, nor will I say he is always wholly innocent, but the remedy for such a condition of things is often very obvious. It is often traceable to the supply being intrusted to a producer with an insufficient plant, and at a price that will never enable him to pay for any addition to it. He is no doubt to blame for taking more work than he can execute; but perhaps he is slack at the time and sanguine, and does his best, but if he is not in a position to start fair with his work at the first, woe be to him if he has a heavy job on hand.

The only satisfactory method in terra-cotta work is to anticipate, as far as possible, the progress of the structure, and this can only be done in the first instance by the architect making the terra-cotta the subject of special estimate as far as practicable ahead of the general work. This is now indeed almost the general rule—and it has many advantages. It brings the architect into direct contact with the producers, and they are in a better position to understand and follow his special requirements. The margin for variation in the general estimate is reduced, and the builder at once knows the amount he has to include for items, which are often a source of perplexity, and with respect to which there is sometimes such wide differences of price as possibly to prejudice one way or the other the general estimate.

The delay in getting out working drawings is also not unfrequently a source of hindrance, and if an architect has failed to realise the necessity of being well ahead with them, it is much less easy for a terra-cotta producer to arrange and set out his work in which, more than in any other material, it is of importance to see the way through from beginning to end, as far as possible from the first step.

It has also happened that difficulties have arisen in carrying out working designs. Comparatively few architects or draughtsmen have had very extensive experience in working out terra-cotta drawings; and although, of course, principles of construction apply in all cases, yet terra-cotta cannot be treated altogether as stone. The form and size of blocks, the bond, the key of the joints, mouldings, &c., require some special consideration if the work is to be carried out to the best advantage. It is not an unknown thing for a producer to struggle with a badly conceived working drawing, and so cause serious delay and inconvenience, instead of at once pointing out the practical difficulties, and suggest an efficient remedy, which might be adopted without prejudice to the constructional lines of the design; yet I venture to believe there are few architects who would not at once recognise and adopt any really intelligent suggestion thus offered when clear from any ulterior object. Nor will I say that the terra-cotta producer has always succeeded in getting the best talent necessary for his work: it is a work to which comparatively few men have been actually trained. For its successful management many good qualities are essential, and to carry out any important work in terra-cotta, there must be constructive skill sufficient correctly to read, and correct, if need be, in relation to other parts, any working drawing. In not a few cases it is the doubtful privilege of the terra-cotta

manufacturer to make the working drawings. For this are required the thorough practical training of a mason and the constructive skill of a draughtsman. There must be a practical knowledge of the material, and the best mode of treatment, sound judgment as to what can and cannot be successfully done; perception sufficiently acute to take in the idea of the architect, or any novel point of treatment; artistic taste enough to insure thoroughly good modelling of all enriched or decorative parts; and sufficient science and practical skill to secure the most perfect system of burning adapted to particular material used. It is not surprising that a producer should sometimes break down on some of these points, in the absence of men specially and technically trained. I am, however, glad to believe that this is a point in which considerable progress is now being made, and, should the use of terra-cotta become still more general, it will be far more easy for producers to meet enlarged demands than it has been in the past, when, unfortunately for themselves, and sometimes for their clients, their attempts to meet extraordinary demands have, in not a few instances, resulted in spasmodic effort and corresponding disappointment.

SOME MORE NOTES IN THE WEST.

CONTINUING our notes on p. 654 relative to the new cathedral at Truro, it may be remarked that the pleasant tone and colour that will be obtained by the admixture of brown Carnarvon granite with the grey granite can now be seen in the finished walls of the crypt. The recent selection of stone involved more labour than at first seems credible. It appears that no less than 72 varieties of stones were inspected and reported upon for the purpose of getting the best that could be obtained for use in the construction of the cathedral. Of course, the cost of working the different stones was kept in view, and wherever practicable, Cornish material was selected. Fourteen Bath oolites were inspected; six Portland oolites, including the Chilmark stone; twenty-three Cornish elvans, &c.; six varieties of limestones from Cornwall and North and South Devon; three varieties of St. Stephen's granite; three kinds of granite in the neighbourhood of Mabe; some beautiful pink elvan, from the neighbourhood of Doublebois, and a specimen of the Trap rock, from Polyphant quarries, near Launceston; also a green stone from Tarten Down Quarry, near St. Germans, the property of the Earl of Mount Edgemore, who kindly offered it for the use of the cathedral. This stone will be used largely by Mr. Pearson in every available place for decorative purposes, such as small shafts, caps, bands, &c., on account of the beauty of its colour—a sage green.

Passing reference has been made to the series of stained glass windows which have just been unveiled in Fowey Church. These memorial windows to the late Dr. Treffry will make the edifice remarkable as one of the most notable and striking in Cornwall. St. Neot Church has long been famed for its wealth of ancient stained glass; but next to St. Neot, no church in the county will be so lavishly decorated in this way. The Church of St. Finbarrus at Fowey is of very peculiar and interesting construction,—one of the very few, too, in the Western peninsula that has a clerestory; and the windows of this clerestory are filled with the figures of saints, chiefly local, in richly-harmonised colours on white backgrounds, giving the fabric a singularly effective and tasteful aspect. The saints represented are: St. Andrew, the patron of fishermen; St. Winn (female), St. Salvador, St. Blaize, patron of the woolcombers; St. Ia (female), after whom St. Ives is said to be named; St. Sampson, of the adjoining parish; St. David, St. Borin (female), St. Cadoc, St. Germanus or St. Germain, St. Dwyn (female), St. Petrocus, of Bodmin; St. Patrick, St. Etha (female), St. George, St. Piranus, patron of the Cornish tanners; St. Nouna (female), Altarnun; St. Gerain, St. Feock, St. Ursula, of the legend of the 11,000 virgins; and St. Tella—all chosen for some special fact or connection. The windows are three-light, and in each a female saint occupies the central place. The same rule is followed in the chancel window, where the figure of St. Catharine is supported by those of St. Finbarrus, the patron saint of the church,

and of St. Nicholas, the patron saint of sailors, most fittingly placed in honour, therefore, in an ancient port like that of Fowey. The Masonic window contains the figures of Hiram the builder, Solomon, and Hiram the king.

It is proposed to erect a laboratory and school of art at Redruth at a probable outlay of £1,200.

A discovery has been made at St. Cleather, near Launceston. Down in the picturesque valley of the Inney, beneath the shadow of great rocks which burst out from the hill-side like semi-fettered and fossilised giants, the remains exist of an old chapel. The external walls may be covered with moss and fern as they are—clearly defined and measure some 27ft. by 17ft. It is regularly planned, duly oriented, and has a western and north entrance. The "Holy Well" is north-east of the ruins. The most remarkable thing is that in this ancient ruin the original stone altar is still *in situ*, and the five consecration crosses are distinctly discernible.

We happened to see a curious tract the other day bearing a poor Cornish history in the 17th century. In it a certain Charles Fitz Gellery, the then rector of St. Dominick, came in for notice. He was a remarkable preacher, and he did not hesitate to use his pulpit for speaking his mind in regard to those who sat in high places. Some of his passages are extremely well expressed. He was very bitter against the landlords for their action in keeping corn, when the people were in need of it, until the price advanced. What would a congregation in these days think of a sermon in this bit of invective? "Heare and tremble all ye Nimrods, and you rough-handed Esaus, grinders of the poor, oppressors of the people; think not to fillip off those curses which your cruelties have squeezed from them! with 'Tush! what care I what the people say?'" and much more to the same effect. He was epigrammatic, too. *John*.—"Not the lion and the unicorn, but the plough and ship, under God, are the supporters of the English crown." There is indubitably a lot of meaning in that. Further on is an account of a debauch amongst Roundheads at Lostwithiel. Thereat, the toast of the evening was, "The Health of the Devil." Whether his satanic majesty was at all the better for having his health drunk in this way does not appear; but this fact was duly noted—possibly as a hint to others—that the man who proposed his health died in the same room shortly after, "raving, and blaspheming, and cursing."

What will ultimately be done with the old Eddystone Lighthouse? This is an important question. Plymouth would like to have it, and has perhaps a stronger claim than anywhere else. The Trinity Beacon upon the Plymouth Hoe will need to be replaced at no distant date, and if in its stead there is re-set up upon that commanding position Smeaton's noble tower, it would be both a useful and ornamental adjunct. The lighthouse will certainly not be taken down until next spring. The Trinity House have already received several applications for it. One has come from the Vicar of Rushorpe, near Leeds, which was Smeaton's birthplace. The Rushorpe folk would like to re-erect it in their midst as a lasting memorial to their great engineering townsmen. Looking at the matter practically, we really feel very doubtful whether the lighthouse can ever be removed in piecemeal. Every stone is cunningly and curiously dovetailed together and bedded in a particularly strong cement. The recent accident at the new lighthouse, which we passingly referred to in our last, was a remarkable one. When the usual weekly vessel for taking the men on shore came, Mr. Edmund, the engineer in charge, standing at the opening, nearly 50ft. above the basement, took hold of the lowering tackle, and called to the man on duty to let him down. Scudgily, the labourer caught hold of the wrong end of the rope and when Mr. Edmund, receiving the word that all was secure, swung himself out, down he went "with a run," pitching upon the rock full 45ft. below! Through a merciful Providence, he escaped with a mere shaking.

At Plymouth, the tower and spire of the new church of St. Jude's in Tophill lane, is up above the belfry windows. It is being erected from the designs of Messrs. Hine and Olgers, of that town. The tramways have been so successful at Plymouth that it is proposed to extend them very considerably. The new public hall

which has just been opened at Devonport is from the designs of Mr. S. Knight, architect, of Cornhill, London. Its cost is £8,100. The style of architecture is Classic. It holds about 3,000 persons. But why, in a town whose very streets are paved with marble, the front of the building is, as the local newspapers record, "elaborately decorated with handsome mouldings worked in cement," does not appear at all clear. During the early stage of the works the western wall fell down. Upon the opening day, the exits from balcony, gallery, and the body of the hall leading into the same staircase, did not win approval, and it has been determined to remedy the defect by an extra staircase. What do all the rich men who have sprung from Plymouth do with their wealth? With the exception of the carillon in St. Andrew's tower and the drinking fountain on the Hoe, and the clock-tower, it would be difficult to point out any modern gift to the town of more than trifling value. Is it that there is no local patriotism or no local wealth, or that there is a superabundance of selfishness among its possessors?

Mr. Alfred Norman, architect, of Plymouth and Devonport, has received instructions to complete the partially-erected church of St. Mark's at Ford, a suburb of those towns. The work will be immediately proceeded with.

At Exeter, it has been resolved to light up the cathedral nave for evening service from Advent Sunday to Easter Day. This resolution offered a fine opportunity for the introduction of the electric light. Two Brush lights would have lit the fine expanse superbly, and thrown out the perspective of continuous roof-groining magnificently. The old-fashioned gas arrangement, however, is to do duty. A continuous pipe now encircles the upper part of each of the nave arcade capitals, and from this are jets at regular intervals. The effect is, I must admit, good, but by daylight the contour of the beautiful-moulded capitals is ruined thereby; for instead of a definitely-defined line at the top, there is now an extra member—a roll, formed by the gaspipe, following the outline of each clustered cap. This is one of those matters which, trifling as it may seem to the outside public, make the professional world deplore that Exeter Cathedral has no appointed architect, under whose supervision such work might be done. The gas-fitting itself has been excellently carried out by Mr. Fred. M. Rice, of St. Sidwells, Exeter, who has been employed from time to time upon cathedral work for nearly 20 years. The first evening service took place on Sunday week, when hundreds were unable to get in, amongst those shut out being the writer, who had taken the precaution to go half an hour before the time. The accommodation which will be thus afforded by the nave will be much appreciated in the city. Exeter has between 40,000 and 50,000 inhabitants, and for these there is only church room for some 10,000.

Mr. F. Medley Fulford's (F.R.I.B.A.) new church of St. Matthew at Newtown, Exeter, is making good progress. It is in the Geometrical style of Early Decorated Gothic, and (exclusive of boundary walls and tower) will cost £6,000. Externally it is of local red brick, with stone dressings. Another of Mr. Fulford's churches—that of St. James's, about half a mile from St. Matthew's—had a new section opened upon the 23rd ult. The new chancel was built three years ago at a cost of £1,550; now, at a further cost of £2,550, the western portion of a fresh nave has been erected; between this and the chancel the remains of the unightly old building remains, a great eyesight than ever. Mr. Fulford's design is a pleasant one, and the piquant west end turret is a particularly picturesque feature. Mr. Fulford is also erecting a mission chapel at Wonford, just outside Exeter, and has just finished a reconstruction of the nave and aisles of St. James's Church, an ugly building of the latter days of King William the Fourth. Over the new west gable is a lead-covered wooden spire, rising to a height of 108ft.; 160 new seats are provided on the ground floor, and 105 in a west gallery at a cost of £2,550. The present section of the entire scheme for rebuilding has been executed by Mr. J. R. Gibbard. The church of St. Petrock, one part of which stands in the cathedral-yard, has been almost rebuilt, and was reopened by Bishop Temple the other day. A new Decorated chancel has been

built, the old one being altered into a baptistery; an organ-chamber has also been added. Messrs. Hayward and Son were the architects, and Mr. W. R. Cummings, also of the "ever faithful" city, has carried out the contract at a cost of £1,250. The new arcade at the head of the High-street is all but finished. It is a prominent feature in Exeter, and has been built from the designs of Mr. James Crocker, F.R.I.B.A., architect, of that city. Several other large buildings in Exeter are also in progress. At some other time we may refer to them. H.

THE FORTH BRIDGE.

THE Parliamentary plans and sections of this work were duly deposited, as required, on the 30th November; and the amended design for the great bridge, by Mr. John Fowler and Mr. B. Baker, the engineers now entrusted with the carrying out of the undertaking, will in due course be brought before the usual Parliamentary Committees for critical examination. The structure is to be a girder bridge of greater strength and rigidity than the Britannia tubular girder bridge crossing the Menai Straits. The two great openings on each side of the island of Inchgarvie are proposed to be traversed by steel girders, 1,700 feet in length. The Britannia Bridge has spans of 460 feet, and for many years it remained the largest girder bridge in the world. Quite recently a structure, having five spans of 525 feet girders, has been built at Poughkeepsie, in America; while several large girder bridges of between 400 feet and 500 feet span have been erected in Germany and Holland; but nothing so great as even one-third of the span of the Forth Bridge girders has yet been attempted. To render so large a span practicable, the proportions usually adopted for girder bridges have had to be entirely departed from. Thus it is usual to make the depth of girders about one-tenth of the span throughout; but the depth of the great girders of the Forth Bridge will be no less than 340 feet, or one-fifth of the span, at the piers, and only about 50 feet at the centre of the 1,700 feet openings. In ordinary lattice girders, the struts are usually made of a couple of angle iron or tee-irons, perhaps 4 inches or 6 inches wide, riveted together; but in the Forth Bridge the corresponding struts will be huge steel tubes, as much as 12 feet in diameter. The underside of the girders will not be level, as in most bridges of the kind, but of an arched form, the girders springing from heavy piers of masonry at a height of 20 feet above high water, and arching upwards until the required headway of 150 feet, for a width of 500 feet at the centre of each opening, is attained. The arched lower member of the structure consists of two steel tubes, tapering from 12ft. to 5ft. in diameter, and spaced 120ft. apart, centre to centre, at the piers, and 30ft. apart near the centre of the openings; the whole being firmly braced together by steel struts and ties, to resist the enormous wind pressure. A cross section of the bridge at the centre would differ little from that of any other big girder bridge; that is to say, the distance between the two girders would be about 25ft., both at top and bottom, which is the width necessary to accommodate two lines of railway. A cross section of the bridge at the piers would, however, show a vast difference. There the two main girders would be no less than 120ft. apart at the bottom, and 50ft. apart at the top, the great tubular struts and ties inclining towards each other, the better to resist the wind pressure. The upper member of the bridge being about 350ft. above high water at the piers, and only 200ft. at the centre, the structure to some extent resembles in appearance, though not in principle, a combination of a suspension bridge with an arch. In stiffness under the working of heavy railway traffic and the action of violent blasts of wind, the structure thus briefly described is expected to excel all existing bridges. The heaviest trains which could be brought on the bridge would only bend the 1,700ft. girder the extent of some 6in., or less than Brunel's 455ft. span Saltash girder bridge was deflected under its test load. Similarly under the action of a wind pressure which would hurl most railway trains in the kingdom off the rails, the lateral deflection would be only some 6in. In an ordinary suspension bridge of equal span it would be as

many feet. The strength and stiffness of the proposed bridge are calculated as partly due to the design and partly to the material. The latter will be exclusively steel, of the greatest attainable strength and ductility consistent with the other qualifications which experience in steel ship-building has proved to be necessary. About 50,000 tons of steel in all will be used in the construction of the bridge, and the estimated cost of the whole work and of the short connecting lines is about £1,600,000. The preliminary surveys and borings have been completed, and the work of the engineers, for the next six months, will consist chiefly in the elaboration of the working drawings, and preparation generally for letting the contract for the work. When the necessary Parliamentary powers have been obtained, no time will be lost in making a start with the work.

SIR ANDREW FAIRBAIRN ON ARCHITECTURE.

ADDRESSING the students and friends of the Selby School of Art last week, at the annual distribution of prizes, Sir Andrew Fairbairn said that recently a Leeds millionaire, being struck with the architecture of some Venetian buildings he had seen while travelling, had a warehouse built from a similar design in Leeds. He asked his hearers to consider, in connection with this, what had been the condition of architecture in this country. In bygone times we had had some wonderful architectural structures—the York Minster, and the Selby Abbey, for instance; but, after a while, the profession of architecture seemed to fall very low indeed, and buildings were erected without any attempt at adornment. Thirty or forty years ago there was a kind of reaction. He remembered this particularly in connection with the Leeds warehouses, in the construction of which the first architectural change was instituted by Mr. Darnton Lupton, at his warehouse in Wellington-street. Many of Mr. Lupton's townsmen were taken aback at the audacity of his alterations; but the result was that almost every building in Leeds, with the exception of the old Cloth Hall, which, he supposed, remained as a monument of what was bad, was reconstructed. Since then there scarcely existed a church in the country that had not been restored, and the change had also extended itself to the Dissenting places of worship. There had, of course, been certain crazes, such as the Gothic craze, and the existing Queen Annie mania, which would, no doubt, in its turn be succeeded by some other style. But whatever might have been the eccentricities of those various styles, the result was a great improvement on the old system of architecture. Within the last twenty years also England had received a powerful incentive to the development of art by the numerous exhibitions that had been held in the country, and, as a consequence, art schools of various descriptions had been formed. The progress of art had been very much assisted by the establishment of the South Kensington Museum, for which we were indebted to the late Prince Consort. That Museum had collected and opened to the whole of England a variety of art treasures almost without parallel. Therefore, the art student of the present day had many advantages which his forefathers did not possess, and it was to be hoped that he would make the most of his facilities. But he wished to offer a few words of advice on this point. It was well known that an Englishman who had a taste for any particular subject always aimed at the top of his particular tree. It must be remembered that it was impossible for everybody to get to the top of every tree, and the moral he wished to point was that people should not aim too high unless they were perfectly certain to succeed.

BREWERIES.

AT a meeting of the Society of Engineers held on Monday evening, December 5th, a paper was read by Mr. W. Barns Kinsey, "On Arrangement, Construction, and Machinery of Breweries." The author first stated the general principles which should govern the arrangement of the buildings and machinery; he then treated the subject of wells and water. A

simple way of preventing contamination was to bore from the surface of the ground, lining the boring with cast-iron pipes, and suspending the pump within the boring, wells of considerable depths having been constructed in this manner. He next described the machinery used in brewing, which he divided into six sections, namely, pumping, grinding, mashing, boiling, cooling, and fermenting and cleansing, stating that the simplest arrangement was by gravitation, the cold water or "liquor" being pumped to the top of the building into a vessel called a cold liquor back, thence it flowed to the hot liquor back to be heated, thence to the mash-tun to be mashed with the malt, from which the wort was run off through a perforated false bottom to the copper to be boiled with the hops, which were afterwards strained from it in the hop-back, and run on to the coolers and refrigerator to be cooled to the required temperature for fermentation. This, the most important process, was carried out in fermenting tuns, and the beer was either skimmed or cleansed. The use of attenuators, cleansing and union casks, together with yeast presses, elevators and lifts, casks, washing apparatus, &c., were duly described and illustrated by models and diagrams. Lastly, the engines and boilers should be of ample power and of the simplest construction, the Lancashire double-flued boiler being most suitable for brewery work.

CHIPS.

The system of tramways first constructed through the city of Oxford was officially inspected by Major-General Hutchinson, on behalf of the Board of Trade, on Monday week, and was opened on the following Thursday. The work has been carried out from the plans of Mr. Brunton, chief engineer, Mr. T. C. Fidler being resident engineer, and Mr. Howard, clerk of works. Mr. E. D. Matthews was the contractor.

The workmen employed on the rebuilding of Mount Stuart House, Rothsay, Isle of Bute, with their wives and sweethearts, were entertained at dinner in the public hall, Rothsay, on Thursday evening, at the cost of the Marquis of Bute, in celebration of the fixing of the roof-tree of that mansion.

A stained-glass window has been placed in St. Saviour's church, Herne-hill-road, to the memory of a deceased chorister. The figures in the two lights are David and Solomon, and the work has been executed by Mr. George Wavell, of Flaxman-road, Brixton.

The parish-church of Kemberton, Salop, is being rebuilt. The old building was erected at the beginning of the present century, and in the wretched taste of that age. The new church is in the Early Geometric style, and the walls are of local red sandstone, with open pitch-pine roofs, covered with Broseley tiles. Mr. Whittingham, of Newport, Salop, is the contractor, and the works are being carried out under the direction of Mr. Joseph Farmer, architect, of Brocklin court, Shifnal, Salop.

A stained-glass window has been placed in St. John's church, Portmadoc, to the memory of the late Mr. John Breese, F.S.A., a well-known Welsh antiquary and bibliophile.

At a meeting of the Lycett memorial committee held at the City of London Liberal Club, on Friday week, it was resolved to commission Mr. Acton Adams to execute a marble bust of the late Sir Francis Lycett, in accordance with a terra-cotta model exhibited.

The local board of West Ham have instructed their clerk, by special resolution, to promote a bill in the next Session of Parliament, giving power to the board to recover payment of fees by persons constructing and altering buildings within their district, and also for extending the powers of the board in regard to making bylaws as to the pollution of water in dwelling-houses and factories, and as to ventilating dwellings and protecting them from fire.

A new London Board-school, in Netherwood-street, Kilburn, was opened on Monday week.

The contract for the erection of the new Tay Bridge having been obtained by Messrs. W. Arrol and Co., of Dalmarnock Ironworks, Glasgow, the work of erecting the bridge will be commenced immediately. The engineer is Mr. Barlow. Operations are to be carried on on both sides of the river simultaneously.

A new deaf and dumb institute, in connection with the Smyllum orphanage, Lanark, will shortly be commenced. It has been designed by Messrs. Pugin and Pugin, of Westminster.

COMPETITIONS.

FULHAM WORKHOUSE INFIRMARY.—The Fulham board of guardians proceeded, on Thursday, the 3rd inst., to consider the selection of plans for the new infirmary. Mr. Storey proposed that the authors of five plans, other than those recommended by Mr. E. H. Currie, the referee, be called before the board to explain their designs. To this an amendment was moved by Mr. Froy, that no other envelopes containing the names of authors of designs be opened, nor the names of authors be made known until the board had decided which plan they would select. Both the original motion and the amendment were lost; but after a long discussion it was resolved that "Experience" in Circle, the plan recommended by the referee, be adopted. The authors of "Experience," as we announced a fortnight since, are Messrs. Giles and Gough.

GLASGOW MUNICIPAL BUILDINGS.—The assessors have issued a list of the mottoes of the designs they have received, which will be found elsewhere in our advertisement pages. It has been impossible for our printer to reproduce some of the emblematic mottoes, so we have had to translate them into words, and hope they will be recognised. We may just remind competitors that, in our opinion, spots in circles, and anchors, and triangles, and the like, are not good devices to use in competitions. They are difficult to identify, and almost sure to be duplicated.

ST. PANCRAS WORKHOUSE.—At the meeting of the board of guardians for St. Pancras, held on the 1st inst., it was decided, on the recommendation of the Workhouse Accommodation Committee, that five architects be chosen by ballot, to send in competitive plans for the reconstruction of the workhouse; also that, subject to the approval of the Local Government Board, the sum of £300 be divided between the four unsuccessful competitors, it being considered by the guardians that the successful architect would be sufficiently remunerated for his trouble by the appointment.

SCHOOLS OF ART.

SALISBURY SCHOOL OF SCIENCE AND ART.—The works of the students of this school were exhibited in the large room in the council-chamber on Thursday week and following days, and formed a large and highly creditable collection of drawings and paintings in the several departments of art. As is well known, this school has attained to a very high position amongst the Art Schools of the kingdom, some of the chief medals and prizes in the national competitions having been awarded to its students. On the present occasion the exhibition showed that the students are still progressing in merit, and that the school is holding its own. The national and local prizes gained by the students during the year were presented to them at a public meeting, held in the council-chamber on Friday evening, when the usual proceedings were gone through in the presence of a large gathering of the friends and supporters of the school.

A reredos has been placed in the parish-church of Frisby-on-the-Wreake, near Grantham. It is of alabaster, supported on a base of Caen stone, and is divided into three compartments of columns of Irish marble. In the central panel is a figure of our Lord in the act of teaching, and in the side panels are the A and Ω. On encaustic tiles introduced into the reredos, are symbols of the Passion of our Lord, including the hammer, the nails, the sponge, and the crown of thorns. Messrs. Jones and Willis, of London and Birmingham, carried out the work.

The annual distribution of prizes and certificates in connection with the science and art classes at the Institute, Stockwell, S.E., took place on Tuesday week. The report of the organising master, Mr. B. J. Rose, showed that during the year 296 students attended the classes, which showed a steady increase. In the science and art examinations the students obtained 55 certificates, nine Queen's prizes, and three third-grade prizes, and 20 special local prizes were also awarded. To the national competition 1,174 works were sent by students, and gained, amongst other awards, three Queen's prizes.

Mr. John Woolgar, builder and contractor, of Horsham, was killed on Saturday morning by a fall from a scaffold, some 30ft. high, on buildings he was erecting.

TYPICAL EXAMPLES OF EARLY GOTHIC DETAIL.—VILLA IN BOWLEY PARK, STAFFORD.—ST. NICHOLAS CHURCH, RUDMERSHAM.—SANDFORD-STREET BOY'S SCHOOL, SWINDON.—HEATHCOTE BUILDINGS, NOTTINGHAM.

OUR LITHOGRAPHIC ILLUSTRATIONS.

TYPICAL EXAMPLES OF EARLY GOTHIC DETAIL.

THE two sketches from Ripon Cathedral in Yorkshire, are specimens of some of the fine Transitional work in which that building abounds. The bay in the nave is interesting, as showing how small our forefathers' respect was for preceding styles, and the unconcerned way in which they altered any work to suit their own convenience. The cathedral is one of the best I know for variety of style; I am not sure whether there is any actual Norman, but with that exception I think every other style is represented. The other sketches are all the result of a little tour in the North-east of France taken a year ago. I fancy most will be familiar to your readers through Mr. Nesfield's fine book, but are such good work that there is not much fear of too often dwelling upon them. The spire at Senlis is, of course, almost if not quite unequalled, and certainly the impression it makes upon one, no matter from what point of view it is seen, is most striking. I only wish my sketch were a better representation of it. The bay from the nave of Chalons-sur-Marne shows a contrast between English and French work, it being, I think, about the same date as the Ripon example. The carving in this church is especially fine, and shows a strong Byzantine influence; it is delicate to the very last degree; the capital I give from S. Remi, Reims, is very fine and delicate, but by no means equals it. The last sketch is an internal view of the cloisters at Noyau, and is to me full of pleasant memories of sunshine and quiet.—A. L. TATE.

VILLA, BOWLEY PARK, STAFFORD.

THIS house, which has recently been erected at a cost of about £1,250, is situated on an eminence in Rowley Park, those windows which face the west commanding a fine view over Stafford Castle and the surrounding country. The walls are of red brick, with red brick mouldings and string courses; the roof is tiled. The walls on ground and upper floors are cavity walls, bonded over cavity every fourth course with thin perforated headers. The internal doors to principal rooms are executed with pitch-pine tiles and rails, and mahogany panels; all other joinery is executed in pitch-pine. The upper portions of windows are glazed with lead light glazing in various units. There are two good attics, and a bath room on second floor. The building was erected by the proprietor, Mr. William Moss, contractor, Stafford; and Mr. Robert Griffiths, County Surveyor, Stafford, was the architect.

RUDMERSHAM CHURCH.

As one of our illustrations, we give an interior view of the restored church of St. Nicholas at Rudmersham, near Sittingbourne, Kent. The

Church consists of chancel, south chapel, nave with side aisles, and a beautiful west tower. The complete restoration of the chancel and of the interior of the nave was carried out some four years since; and during the demolition of the high-backed pews which completely choked up the whole of the nave, the architect (Mr. S. Slingsby Stallwood, now of the firm of Morris and Stallwood, architects, Reading), discovered portions of the old rood screen beneath the floor and amongst the pewing, the sill and parts of the lower panelling being actually *in situ* serving to support the pulpit and reading desk. These interesting fragments were carefully preserved, and the screen has now been restored on the old lines, and the ancient woodwork renewed and taken as a guide to the new. The cross erected upon the screen measures 10 feet in height, and the four points contain sculptured representations of the four evangelists, with the *Agnus Dei* at the intersection. The church contains some very interesting 15th century oak screens and sedilia, all of which have been carefully repaired. The south chapel is private property and remains untouched, but the interior has been made "decent," and, by the addition of a second altar, restored to its original purpose.

SANDFORD STREET BOARD SCHOOLS, SWINDON.

THESE schools have been erected for the Swindon School Board in the New Town, to accommodate 794 boys. They are one of a series of schools erected by the Board to meet the educational needs of the Old and New Towns. The school is divided into three sections, junior, middle, and senior, with separate entrances and cloak-rooms, also separate play-grounds, play-sheds, and offices for each division. The head master's room is placed so as to give immediate access to all three, and commands the main entrance. The middle school is placed on the first floor above the junior school. The schools are built of local bricks, the facing being of a yellow grey brick, like London stocks, from the neighbouring parish of Dauntsey. The arches, quoins, and dressings are of thin, red bricks, specially made by Mr. Turner, of Swindon, working five courses to four of the backing. The name of the schools is arranged in a deep red, terra-cotta panel over the entrance. The dormers are also enriched with terra-cotta panels, the date of erection, 1880, alternating with the monogram S.S.B. The roofs are covered with Wilkinson's tiles. The schools are heated entirely by open fire-places, fitted with Elsey's patent warm-air grates, and ample ventilation is provided by Tobin tubes in every window sill. These are fitted with sliding covers; the upper part of the windows are hinged to open inwards, and are fitted with Elsey's patent levers. The lower parts of the windows are arranged as double hung casements. The buildings have been erected by Messrs. D. C. Jones & Co., of Gloucester, from the designs of Mr. Brightwen Binyon, A.R.I.B.A., of Ipswich, at a cost of £5,143, including all fittings.

HEATHCOTE BUILDINGS, NOTTINGHAM.

THIS block of buildings has recently been erected at the angle of a new street, recently opened in a populous portion of the borough of Nottingham, and which has been named Heathcote-street, after an inventive gentleman who made sundry improvements in the manufacture of lace and other articles. The block consists, on the ground floor, of eight sale shops and other business premises, and above are warehouse let off for the lace trade, which is the chief industry of this thriving town. The main supports of the building are greenmoor stone and cast iron, the superstructure is the best Nottingham red brick, with Hollington stone facings. Terra-cotta has been used in panels, gables, and other places. The trefoil headed panels above the plate glass of ground floor are filled in with highly-toned stained glass in lead geometrical patterns. The whole has been erected from designs by, and under the superintendence of, Messrs. S. Dutton Walker and Howett, of Nottingham, architects, by Mr. Henry Vickers, of Nottingham, contractor.

The first portion of a new church is in course of erection at Northam, near Southampton. The contract includes the erection of nave, chancel, chancel-aisle, and vestry, and has been taken by Messrs. H. and J. Bull, of Southampton, for £4,000.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The fortnightly meeting of this association was held last week. A paper was read by Mr. James Gordon, entitled "Architectural Notes in Normandy," giving some account of a sketching tour recently made by the author and two other members of the association in that part of France. Taking the order in which the towns on the line of route were visited, Mr. Gordon proceeded to describe the attractions which each presented to the architectural student, and the peculiarities of general design and detail of the various buildings. Rouen and Caen with their environs, Constance and Mont St. Michel, came in for a larger share of notice, as being especially rich in objects of interest. Many other places visited were also described. Normandy, it was stated, was, with perhaps the exception of the district round about Paris (the old "domaine royale"), the best field in which to study the beginnings and development of Gothic architecture, the wealth of examples affording abundant opportunities for comparison between the various periods. But, Mr. Gordon said, while the field in Normandy thus offered to the student quite an "embarras de richesses" most convenient for systematic study, it was not to be understood that the study of such monuments or such remnants of them as remained to us at home should be neglected. On the contrary, these were deserving of, and should first receive, the most careful study, for, although unfortunately for the most part only fragmentary, they were in no way inferior to the French examples. Few, if any, of the latter could be compared, as regards chaste refinement of detail, with what is left to us of the abbey of Dryburgh or Dunsyre, not to mention others.

CHIPS.

Commodious new showrooms are about to be erected on Pride Hill, Shrewsbury, by Messrs. J. Jones and Son, cabinet manufacturers, of Oswestry, which will be built by their own workmen, from the designs of Mr. W. Charles Evans, architect, 3a, Poets' Corner, Old Palace-yard, Westminster.

A scheme for the drainage of Woodford, South Essex, has been prepared for the urban authority of that district by Mr. Lewis Angell, C.E., surveyor to the West Ham local board. The estimated cost is £30,000.

The Grays Thurrock Gas Company have recently extended their works by building a 52ft. brick and concrete tank, engine and boiler-house, oxide and purifier sheds, coal stores, offices, photometer-house, boundary-walls, &c. The engineer was Mr. A. Williams, of 64, Bankside, and the contractor, Mr. W. J. Botterill, 110, Cannon-street, E.C.

Extensive alterations have been going on to premises, No. 8, High-street, Hanley, for the Staffordshire Union Bank, Limited, a new banking company. The whole of the works, and also the decorations to manager's and other rooms, some additions, at rear of premises, &c., have been carried out under the superintendence and from the plans and detail drawings of Mr. Elijah Jones, of 18, Pall Mall, Hanley. Mr. John Roberts, jun., is the contractor.

A new chancel, which has been added to Christ Church, Luton, from the designs of Mr. G. Vials, A.R.I.B.A., was consecrated on Wednesday week by the Bishop of Ely.

A new mansion, to be known as St. Andrew's, has just been completed on the hill side overlooking the Spey, at Craigellachie, near Elgin. It is in the Scottish Baronial style, and has been erected from the designs of Messrs. A. and M. Reid, architects, of Elgin. The chief contractors were, masonry, Messrs. Dow and Roy, of Rothes; carpentering, Messrs. A. and R. Dunbar; slating, Mr. Cameron, Elgin; decorations, Mr. Morrison, Dufftown.

The Merthyr rural sanitary authority resolved last week to raise the salary of Mr. J. Jones, their surveyor, from £160 to £180 a year.

The Brighton town council have adopted recommendations by the borough surveyor that the damage done to the groyne by recent storms should be at once repaired, and that the groyne opposite Percival-terrace should be rebuilt for 125ft. at a cost of £600, and that opposite Chesham-place for 93ft. at a cost of £350. The work will be carried out by Messrs. Patching and Sons, builders, Brighton, under their contract with the corporation.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 3fr. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—E. and S.—M. H.—R. M. and Son.—B. of B. W. J. S.—E. and Co.—J. H.—W. P.—G. M. and Son.—W. and Son.—W. P.—E. C. and Co.—C. and S.—G. and P.—M. and Co.

J. M. J. (Not so uncommon, unfortunately, as to call for special notice, but certainly none the less to be guarded against.)—MASON. (We do not know.)—J. F. D. GOODBYCH. (Possibly of the Secretary, if still in print. We have not published it.)

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—One of Them, Sir Naw Beuan, Self Help, T. Carré, To Be or Not to Be, K. E. S. W., Hugh, Norman, Junior, Sise qua non, Cymro Bach, Tempus Fugit, Wensley Dale, Fudge, L. in circle, V. in circle, West Countryman, Toledo, T. F. in circle, Con, Grosvenor, Try, Cross in circle, K. Exegi, Economy, Hall in circle, Melton, Yorkshire, Amicus, Confido, Tempus Fugit (2), T. D. in circle, Try Again, Ben, I Try Again, Nil Desperandum, Darby and Joan, Finem respice, Sol et Scutum, Gensborne, Ars Longa, T-square, V. in circle, Trial Dado, Lerec, Will, Economy, Triangle in circle, Chip, Damion, Iota, A. Grey, H. H. Chip, Jek, Jake, Ars Longa Vita Brevis, Subjudice, Toledo Dado, V. in circle, Simple-minded.

TO BE OR NOT TO BE. (All drawings sent in are to have the name and address of the authors.)—JUST MY LUCK, OLIVER TWIST, DADO, DEBRY, AND OTHERS. (The 60ft. frontage is the frontage of the building; side lights are better avoided. The stage may be either movable or not. The drawing-room is not for drawing classes. A bar need not be provided.)—S. H. E. PETER, EFFICIENCY, J. T. (Competitors have not to pay for return postage.)—SIGMA, ARS LONGA VITA BREVIS, F. F. in circle, HUGH, WILL, CECIL, C. F. OGDEN, SIR NAW BEUAN, L. in circle, YARRA YARRA. (The reading-room may be used as a green-room.)—PUPIL J. (A hall to hold 200 will do.)

Correspondence.

PROVINCIAL ARCHITECTS AND THE INSTITUTE.

To the Editor of the BUILDING NEWS.

SIR,—A printer's error in my letter of last week makes an allusion which I made to the Dentists Act (not dentists' art as printed), unintelligible to most readers. What this recent enactment had to say to the status of architects may not at first sight be more intelligible, and want explanation. What I conceive is the ultimate point to which we all wish to tend, is that the profession of an architect may be one with a recognised legal status, and that it shall not be open to ignorant and unqualified persons to constitute themselves architects by mere assumption of the title.

The recent enactment known as the Dentists Act has an important analogous bearing on this point. Hitherto anyone—a handy man, a waiter graduate in cork-drawing, as a matter of fact a

great many jewellers and silversmiths—were at liberty to announce themselves as dentists, and work their will on the molars and nerves of her Majesty's lieges. By a short Act of Parliament, with an elastic and reasonable procedure, this has been put an end to. Under it existing practitioners who were not legally qualified surgeons were not absolutely required to undergo examination and registration, but it was left optional to them to do so. For the future it was enacted that all dentists must be duly qualified registered practitioners. No hardship was thus inflicted on any existing interest. As a result, however, there was a rush of miscellaneous qualified practitioners of every age from all parts of the kingdom to offer themselves for examination, and secure the status attaching to registration. The examinations under these peculiar circumstances were of a common-sense and lenient character—a conversational inquiry in many cases of old gentlemen as the examiners, sufficient to establish in their mind that the candidate had a fair knowledge of his business. The successful result is that, without any revolution, dentistry was elevated from a questionable position to that of a respectable recognised profession.

It may not be practicable, perhaps, in our time to achieve for architects the legal status we all desire; but I submit there is at least an analogy for our position in the instance I have quoted. We might, I venture to suggest, go a long way towards our end in view by voluntary action. Not by pursuing our course as heretofore, laboriously entailing a small percentage in numbers of the architects of the kingdom to "Join the Institute" as Fellows or Associates, under conditions in many cases distasteful and nugatory; but by a system of registering, under the authority of the Royal Institute of British Architects, the name of every fairly competent and qualified practising architect in the three kingdoms held in his locality of practice in honest and honourable repute. What the conditions for such registration should be in detail it is unnecessary to enlarge on, but they should be as encouraging as possible. I would suggest, however, some inducements which should not be held out—viz., that the subscription should be £4 4s. per annum; front seats for the council at the R.I.B.A., if an aspirant should reach that awful elevation; and right of succession by rotation to the Presidency, be he an eminent one or not. Alluring as these may seem to some minds, they are not effective baits for the long lines that are wanted to draw widespread provincial practitioners into the reach and influence of the Institute.—I am, &c.,

Dublin. THOMAS DREW, R.H.A.

LONDON ARCHITECTS WITH PROVINCIAL WORK.

SIR,—London architects who have work in the provinces are very hard upon us poor local builders in either not giving quantities, or giving them prepared by a London (and to us a perfectly unknown) quantity surveyor, while it is notorious that quantities by a local surveyor are always understood better, and we have more confidence in them, which saves cost to the clients. I will give an example to illustrate what I mean:—

The Government recently advertised for tenders for building a post-office in Yorkshire, but no quantities were supplied, and I employed a local quantity surveyor to measure up the work. I did not get the job, and yet I had to pay him, although he admits that he has got the quantities out for four contractors (including ourselves), and that one of his clients was the successful contractor, and has added 2 per cent. on the amount of his contract to pay the surveyor, who must have made 5 or 6 per cent. on the cost of the job. It would have been nearly as bad if a London surveyor had been engaged, as we should have to get a local surveyor to explain the architectural terms they employ in our local phraseology.

I particularly object to London quantities when the work is erected by subscription. I was recently solicited to subscribe towards building a chancel to our church, but I found that a London architect was employed, and that the quantities would be prepared by a London surveyor, and that if I tendered I should have to pay at least £1 1s. to a local surveyor to interpret the items in the quantities. I, therefore, refused to subscribe, and shall not tender

for that or any work unless quantities that we can understand are supplied, or unless an allowance is made for tenders. I inclose my card.—I am, &c.,

A SUCCESSFUL BUILDER.
Dec. 5th.

DUBLIN SCIENCE AND ART MUSEUM COMPETITION.

SIR,—Some of the competitors in this important competition have already had their designs returned to them. No explanation has been given, no cause assigned; and there have yet but 15 days—but 13 working days—elapsed since the delivery of the designs to afford opportunity for the proper testing of about 70 sets of drawings as to their compliance with the conditions set.

By the "Instructions," the assessor's estimate of probable cost being in excess of £100,000, or any infraction of the conditions would alone warrant the summary exclusion of a design from the competition.

Can it be possible that within the period which has elapsed, all the designs have been properly tested as to their provisions respecting the required space, and as to their probability of execution within the prescribed amount?

The "Instructions," while seeming fair on general grounds, were somewhat vague on those which many would consider most particular. They left entirely to the judgment of competitors the requirements of each department, simply giving an amount of floor area to be provided for each, without reference to the question what department, or what portion or extent of each department, required top-light, what side-light; nor did they give any particulars as to the requisite arrangements of any of the departments.

They did not interdict the use of colour to show on the plans a competitor's proposal for the allotment of space; and architects, at least, will agree that such a method is the simplest for the indication of sub-division of space on a plan.

It is true that in one paragraph of the "Instructions" they say that "the drawing shall be in pen-and-ink, without colour of any sort." But to the understanding of those accustomed to the literal interpretation of English prosody, that paragraph refers distinctly only to the paragraph immediately preceding it, which reads thus:—"Such perspective view shall be drawn to such a scale," and so on, about the size of the perspective and its mount.

Colour was forbidden on the elevations, but no mention whatever was made of any prohibition as to colour on the plans.

It is also to be observed, on the score of fairness, that when conditions are set, all the competitors should be adjudged equally upon them. The dimensions of the site were not accurately given; and while the site is described as level, a fall exists in at least one direction, which would admit of—probably call for—particular treatment. Some competitors may have availed themselves of this "local" knowledge. Has the assessor inquired into this view of the matter? Would it not be manifestly unfair to adjudge the designs on any other than the lines given?

Under all the circumstances, surely there is cause to complain that no explanation has been offered upon the return, within so short a period, of designs to competitors who have given thought, time, labour, and money in their efforts to interpret "Instructions" which were, at the least, vague.—I am, &c.,

Dec. 1st. FAIR COMPETITION.

PRELIMINARY COMPETITIONS.

SIR,—As the idea of conducting open competitions in two heats is a novel one in practice, though I have joined with others in advocating it privately for years past. I am glad to notice the comments and suggestions of "A. B. C." and "Vigilans" on the subject; because, as we may take it for granted that competitions will continue as long as building, it is important that the conditions under which they are conducted should be developed on principles of equity and morality as rapidly as possible. I recognise in the division of competitions into two stages a great stride in the right direction, and regard it as removing many of the objections which architects of high standing have urged against entering the lists with all comers, while

quite willing to break a lance with a select few of their peers whom they may esteem to be worthy of their steel.

But as indicated by "A. B. C." in his second letter, a scale of 1-20th of an inch to 1 ft. is too large for sketch designs, in which I apprehend the general scheme and grouping of each competitor are the two principal objects sought for. This could be done perfectly well to half the scale, and would save an enormous amount of labour, for a 20-in. scale, while too small for precise accuracy in detail, is sufficiently large to enforce careful determination of proportion, not only in the large masses, but also in individual features.

Why should your correspondents discuss the distribution of the £150 per head to be given to each competitor in the final heat, as though it were a premium awarded for excellence in the first one, when the conditions for the Glasgow Municipal Buildings competition distinctly state that "each of the competitors so selected shall be paid the sum of £150 towards his expenses, provided he comply with all the conditions to be hereafter prescribed for such final competition." Obviously, the sum is intended partially to defray the cost of preparing the matured, not the sketch, design. Again, "A. B. C." seems to regard the drawings in this second competition as merely an enlargement of those submitted in the preliminary contest; but the above extract, and more directly the terms of Clause 5—viz., "Separate conditions will be issued for the final competition. They will be in strict accordance with the above, so far as applicable, but will contain such additions or alterations as may be deemed necessary, &c."—clearly point to something more sensible than a mere mechanical enlargement. I anticipate that the assessors will avail themselves of the good points, not only in the selected designs, but in any of the others, and embody them in the final instructions, if not as requirements, at least as recommendations, which each competitor will be expected to work into his matured design, while holding to the general disposition or scheme of his first sketch, the merits of which secured him a place in the second competition. In accomplishing this, quite as much ingenuity and skill may be demanded as was required for the sketch design, and might result in a complete rearrangement of the order of merit attained in the first contest. It would, I think, be unwise to announce any order of merit in the first competition; and it would be well if the assessors could possibly avoid, even mentally, arranging the selected six or ten as 1st, 2nd, 3rd, &c. But it is perfectly evident that should they arrive at a definite order of merit in the first competition, the assessors should have power to vary it in the final competition, "if they thought right," as "A. B. C." with charming simplicity, notices; else would the final award be prejudged, and the second competition a veritable wearing of the flesh.—I am, &c., G. W. B.

WALSALL SCHOOL BOARD.—COMPETITION FOR NEW SCHOOLS, WOLVERHAMPTON-ROAD.

SIR,—The previous competitions being unsatisfactory, it has been deemed necessary to send to the Board the following memorial, drawn up at a meeting of the architects practising in the town, to which the subjoined reply has been received. JONATHAN ELLIS, jun.

Walsall, Dec. 5th.

TO THE WALSALL SCHOOL BOARD.

GENTLEMEN,—In view of the approaching Competition for Proposed Schools, Wolverhampton-road, Walsall, we, the undersigned architects practising in Walsall, beg to submit the following suggestions for conditions of competition for your consideration.

The said conditions are, we think, strictly impartial, and are precisely the same as those recommended by the Royal Institute of British Architects at the General Conference, 1881, and subsequently adopted by the Glasgow, Birkenhead, and other Corporations, in recent competitions.

First.—As the preparation of finished drawings entails considerable labour upon the competitor, and the object of the competition is to obtain the most suitable plan, we think the said object may be equally well obtained by dividing the competition into two parts, Preliminary, and Final.

The Preliminary Competition to consist of geometrical drawings in pencil only; and that from the designs submitted, a number in pencil may be selected for Final Competition.

The four unsuccessful competitors to receive the sum of £5 as an acknowledgment for their trouble.

Second.—That in the Final Competition, the mode of

finishing the drawings should be distinctly set forth, whether to be finished in ink or colour.

We suggest that perspectives be strictly excluded, owing to their misleading tendency. Should you decide to admit these drawings, the way in which they are to be finished to be distinctly stated.

Third.—That the board state the kind of desk they wish to adopt. We also think it would be much better to name the sum proposed to be expended—say, £5,000—rather than state the building to be of a plain character, as such a term is open to various interpretations.

Fourth.—We consider it absolutely necessary that an architect of eminence should be employed to advise the board in their selections, and that his report on the Final Competition be published in the local papers.

Fifth.—That the drawings submitted in the Final Competition be exhibited.

Walsall, Nov. 21st.

[REPLY.]

RE WOLVERHAMPTON-ROAD SCHOOLS COMPETITION.

SIR,—The memorial, signed by yourself and other local architects, dated the 21st inst., and which I received from you, has been considered by the School Board at a Special Meeting to-day, when the following resolution was passed, viz.:—

"That the Board acknowledge the receipt of the memorial from local architects relative to the Wolverhampton-road School Competition, but that the memorialists be informed that the Board cannot adopt or act upon the conditions and proposals contained therein."

Walsall, 30th Nov."

PORTLAND CEMENT CONCRETE AS A CONSTRUCTIVE MATERIAL.

SIR,—The disaster at the Calf-rock lighthouse appears to have furnished about as good an illustration of the kind of material we have in "Portland cement concrete" as its advocates could have desired. According to the reports in the daily press, we are told that the lighthouse was 150 ft. high, and built of brickwork, its thickness at the base being 5 ft. Thirty feet in height of the lower portion has been strengthened with concrete blocks, and it would appear that this 30 ft. is all that is left intact. At some distance from the tower was a kitchen, built entirely of concrete, and of this the lighthouse-keeper writes:—"We made for the west house (after the tower was blown partly away), and after being there an hour we determined to make for the kitchen, it being, in our opinion, the strongest; we succeeded in getting there, but the sea and waves were most terrific. . . . We have stuck to that shanty ever since, and thank God it did not deceive us."

It would be well to know more about that "shanty," and the system adopted in its construction.—I am, &c., THOMAS POTTER.

CLERKS OF WORKS.

SIR,—Although architects have many associations and societies for the purpose of rendering and receiving mutual aid in various ways, a large class of men fulfilling responsible positions have none, at least, so far as is known to the writer—viz., "clerks of works and foremen builders." I think so numerous a body of men would find many advantages and derive much assistance were they to combine to form an association similar to the "foremen engineers," and many others.

As the BUILDING NEWS is largely read by the class named, and the suggestion is a good one, might I ask a favour in soliciting the valuable aid of its columns in giving publicity to the subject, and in obtaining the views of others competent to give their opinion and advice.—I am, &c.,

ANOTHER CLERK OF WORKS.

TESTING TRAPS.

SIR,—To save repetition, I would refer Mr. Hellyer to Mr. Buchan and my letter in your issue of the 2nd inst. as to the water supply, and he need not refer to conflicting reports, as he can obtain authoritative information from his own foreman as to the dip of traps, &c.; I would call Mr. H.'s special attention that it is not siphonage, so much as it is the momentum out of traps, that our public experiment went to prove, as Mr. H. spoke of the latter in the pages of his book. I wish also to ask him if, in the whole course of his lectures, he once mentioned the momentum out of traps? I believe we were the first to discover this, and am thoroughly convinced that had it not been for our demonstrating this important defect in the U-trap it would not yet have been brought to light. I am glad Mr. H. acknowledges the importance of traps holding their seal under every treatment.

I cannot agree with Mr. H. that the V-trap

is as self-cleansing as he reports, as it is no better than the new pattern U-trap. Mr. Buchan says we have not tried it. I must tell that gentleman we have, and Mr. Davies took the notes at the time, and promised to send a report in one of his articles to the BUILDING NEWS on "Practical Plumbing," so he is responsible for not having done so, and I have written to that gentleman on the matter. Mr. H. says he can siphon out Mr. Davies's pattern U-trap. This may be so; but I always understood that Mr. D. recommends ventilation with his pattern trap, as I do myself with ours, so I fail to see anything against us in this. With regard to Fig. 3 of Mr. Hellyer's letter, I cannot see why the dip part of this trap should have been affected with sewer gas any more than the top or sides; in fact, his own drawing shows that the sides are also eaten away, and therefore water would have at once run out of the U- as well as it would out of the U-trap. I am sorry to inform your readers that, owing to the gales on Saturday and Sunday morning, Nov. 26th and 27th, the scaffold to which the experimental stack of soil-pipe was fixed, was so seriously shaken and strained that we have been compelled to pull it down, but hope to erect a more substantial one at an early date, when, as hitherto, all will be welcome to judge for themselves which is the best form of trap.—I am, &c., J. PULLEN, jun.

73, Penton-place, Walworth, Dec. 5th.

SIR,—If Mr. Pullen, jun., will read my letter again, he will find he is the subject of an ocular error. I did not state that the w.c. was supplied with a 3 in. pipe, but the dribble of water was not equal to a stream through a 3 in. pipe, to which statement I still adhere.

To show how unsatisfactory the proceedings were, I should like to state that when I arrived home on Tuesday night a letter awaited me from a gentleman in Sheffield, thanking me for the letter you published, also condemning the so-called tests in such strong terms that, without his permission, I should not like to state them. There is one part of the experiments with the U-trap that has not been mentioned in the reports—that is, when the top of the soil-pipe was stopped up, and the basin of water on the U-trap (on the top scaffold) was discharged, the U-trap on the opposite side (which had 1 1/2 in. dip, owing to its not being level) had an inch of water drawn out of it. Now, if the U-trap had been level, I believe it would have become untrapped. Now, with regard to the meeting on Monday, the 21st. It seems strange, after a committee had been selected to finally test the traps, that the meeting should be adjourned without that half of the committee in favour of the round pipe trap knowing anything about it; but I suppose Messrs. Pullen and Davies thought they could do better without them.

About twelve months ago I saw a good instance of the cleanliness of U-traps. Owing to some alterations, four had to be removed that had been in about twelve years. Although they were fixed under pan-closets and 3 in. services, they had not 1-16th of an inch of corrosion on them. The same could not be said of U-traps if they had been fixed half the time.—I am, &c., J. W. HART.

91, Dorset-road, Clapham-road, Dec. 5.

ERRATUM.—TRAP-TESTING.—In Mr. S. Stevens Hellyer's letter on this subject that appeared in our last week's issue, read in thirteenth line, fifth paragraph, "Mansion" instead of "Mansergh" trap, and again at twenty-second line, same paragraph.

AN IMPROVED MODE OF CONSTRUCTING BUILDERS' IRONMONGERY.

SIR,—I take the liberty of sending you a short description of a mode of constructing certain articles of builders' ironmongery, which would greatly facilitate the fixing, and insure accuracy. This would apply particularly to sash-pivots for sashes that are hung on centres, thumbscrews for door shutters, and like fittings. The component parts of the above being independent or quite free of one another, require their relative positions to be very exact for them to work correctly.

Suppose we take a sash-pivot as now in use; it is cast somewhere on the surface of a plate that is made in the shape of a parallelogram or oblong; we have no means to readily determine the exact positions for pivot and socket in the frame and sash, or, rather, we can determine the positions; but owing to the shape of the plates, we cannot with certainty be sure they will occupy them.

The construction as now proposed: The plates to be in form of a number of detached segments of circles, the working parts of fittings to be cast central on one of the segments; the edges of these

plates might have impression left to denote centres. Three segments of circles 1 in. radius, with centres 2 in. apart, might be taken as a standard for plates; this would give a length of 2 in.

To hang a sash on these pivots, draw a horizontal line, as is usual, on the stile of sash and frame, return it on edge, a central line at right angles to this. Where the lines intersect, place the middle segment of plate; mark the centres on this line. Of course the intersections of the lines will be one centre; three shallow holes on the edge of sash, and the same on the frame, made with an inch boring-bit, would insure a much more rapid and satisfactory job than it is possible to accomplish with oblong plates that have to be sunk into wood by means of chisel.

There is no need of details for thumb screws; this principle, with a slight modification, might with advantage be applied to sash-pulleys. In sketches,

Fig. 1 is a shutter stud; Fig. 2, thumbscrew; Fig. 3, sash-centre; Figs. 4 and 5, sash-pulleys.—I am, &c., R. Gough, 123, Lower Kennington-lane, London, S.E.

CHIPS.

The export of deals from Montreal to the United Kingdom during the season of 1881 just closed stood at 33 cargoes, containing 21,838,287 ft. against 19,781,885 ft. in 1880, showing an increase of 2,056,402 ft. when the one year is compared with the other.

Amongst the gentlemen knighted by the Queen on Wednesday were Dr. George Birdwood, C.S.I., who has travelled in India to collect specimens and report for the South Kensington Museum; Mr. Erasmus Wilson, of dermatological and Cleopatra Needle fame; and Mr. Andrew C. Ramsey, of the Geological Department.

The Court of the Carpenters' Company have voted the sum of £1,000 towards the building fund of the City and Guilds of London Institute for the Advancement of Technical Education.

The Health Congress and Exhibition, to be held at the Pavilion, Brighton, will be opened on Monday next.

We are glad to learn, upon inquiry, that Mr. Street, R.A., is gradually recovering from his illness, with which he was suddenly seized about three weeks ago.

On Tuesday the church of St. John, Neath Abbey, which has been undergoing repairs and restoration, was reopened. The alterations and additions comprise a new heating-apparatus, new seating and choir stalls, tile floors to all the passages, and the decoration, the cost of the whole exceeding £1,300. The work has been executed from the designs of Mr. Edwin M. B. Vaughan, A.R.I.B.A., of Cardiff, by the contractors, Messrs. Thomas, Watkins, and Jenkins, of Swansea.

It has been decided to enlarge and improve the parish-church of Kew, and a committee has been appointed for that purpose. The intended works include the increase of accommodation to 737 sittings, by the erection of a transept and clerestoried chancel; the re-seating of the entire church, provision of choir-stalls and organ-chamber, raising the ceiling, improving ventilation and heating, and the formation of new entrance. The estimated outlay is £5,500.

Subscriptions are being raised and a committee has been organised for the restoration of St. Pinnock Church, Cornwall, which has become through neglect and decay an almost ruinous building.

The Metropolitan Board of Works, at its meeting on Friday, approved a recommendation from the Building Act Committee, arising out of the recent fall of a house in Clifton-road, Maida-vale, that, in order to prevent accidents to new buildings in course of erection, all drains should be laid in the junctions made, and the excavations filled in to the satisfaction of the district surveyor before commencing the walls.

Intercommunication.

QUESTIONS.

[6803.]—**Hoop-Iron Bond.**—Should hoop-iron bond be carried through the openings, and afterwards cut and turned up and down, or turned up and down, and not carried through? Which is best?—SIGMA.

[6804.]—**Diocesan Surveyors.**—In whom or what body is the appointment of diocesan surveyors vested?—X. Y. Z.

[6805.]—**Bath.**—A large swimming bath, lined with Portland cement, in use for sea-water, is too black-looking. I want, if possible, to make the sides and bottom white. Paint will not stand; the salt now in the cement discolours it and throws it off. Tiles are too expensive. Should be very glad of a suggestion.—ALBA.

[6806.]—**Aquarium.**—I should feel obliged for information as to the best method of fixing the glass fronts to large tanks in a public aquarium; also the most suitable kind of glass, and where to obtain same, for use in the North of England.—FISH.

[6807.]—**Excise.**—Will any of your readers inform me how I could obtain a situation on board the Revenue cutters; if there is any exam. to pass, and if the wages are good?—E. C. P.

[6808.]—**Brick Arcade Arches.**—Will Hugh McLachlan, or other able contributor, kindly advise me in the following? In turning the arcade arches in brickwork of a new church, is it necessary to have a centre made for every arch, and should they remain in position until the whole of the weight is placed upon the arches; or is it the custom to make centres for the one side only, and after weighting the arches a little and allowing the mortar to set to strike the centres and use for the opposite side? A reply will be thankfully received by—ONE IN DUBER.

[6809.]—**Repairs.**—Some houses are left by will to A., and at his death they are to become the property of B. Can B. compel A. to do any repairs to the property? If so, what repairs? Has B. or his agent the right of entering the houses to note their condition? Can B. compel A. to insure the property? If not, can B. insure it himself?—C.

[6810.]—**Ownership of Drawings.**—A. (a builder) contracts with B. to construct a building according to drawings and specification prepared by an architect C., who favours A. with a set of tracings, &c., signed by himself as evidence of their being correct. Such building completed, the period for maintenance passed, and all payments settled, C. requests A. to return the drawings; but A. refuses to do so, alleging they are now his property. Has A. any right by law or custom to retain such drawing, and, if not, what would be the best mode of recovery?—C. B.

[6811.]—**Force of Impact.**—What would be the force of a blow, measured in weight, which would be caused by the fall of 3wt. of iron from a height of 7 in.? For my purpose, the smaller variation due to friction with the air in falling may be omitted. Should feel obliged if the formula, as well as the result, were stated, and the authority for the formula.—R.

[6812.]—**Ventilating Pipes.**—I have just completed a villa, and having specified one ventilating pipe to soil-pipe to be carried to ridge, I am required by the surveyor to carry up two more, a great discommodation to the elevation, one from the servants' w.c., which is trapped, and only fit from foot of soil-pipe, with no trap intervening, and another from w.c. traps, all carried to the ridge. In addition to the w.c. traps, there is a siphon on the house side of sewer. I shall be glad of information if the above is consistent and necessary, as very little, if any, sewer-gas can penetrate past the siphon, the sewer being well ventilated in road.—ARCHITECTUS.

[6813.]—**Water.**—Will some practical reader advise me what to do in the following case? Having built a pair of villas in the summer, the cellars, which were then perfectly dry, and which were excavated to a depth of 6 ft. below the surface of the ground, are now covered with water about 1 ft. in depth, as are also the excavations for cesspools and rain-water tanks, the water in them being from 2 to 3 ft. deep. The cellars are paved with bricks laid in mortar, and grouted in cement. I have had them pumped dry, but the water rises again, and, therefore, I conclude it proceeds from land-springs. Is there no remedy but to drain the land? How is this done? Would not asphalt or cement keep the water back? Any information respecting this matter will be thankfully received by—URGENT.

[6814.]—**Moving Load of People.**—I am designing the construction of a gallery in a theatre with risers 18 in. high. Should I take the permanent load to be (1) the weight of a dense crowd, or (2) the weight of a dense crowd multiplied by its velocity on jumping down 18 in. from step to step, and what margin of safety should be allowed in either case?—X.

[6815.]—**Hospital Construction.**—When hospital wards have central stoves, I find the flues are sometimes taken across under the floor and carried up in the side walls, and sometimes carried up vertically at once. Which is the best method, when one ward is over another? Are pilot stoves necessary in the former case? How are the flues usually disposed of in using Mr. Saxon Snell's Thermo Hydric Stove in the centre of room?—SIGMA.

[6816.]—**Cracked Sewer Pipes.**—Some pipes about 12 in. in diameter, laid about thirty years ago from S to 10 ft. from surface in compact clay, were found cracked, apparently from pressure. Can any reader suggest cause of this, and say what would be a safe and reasonable depth from surface of road for laying for surface or sewage drainage, 9 in., 12 in., 15 in., 18 in., or 24 in. pipes, so as to resist injury from a ten-ton roller? Also, what thickness of pipes would be safe.—OALGEB.

[6817.]—**Whitewash.**—Would some brother reader who has had experience in removing whitewash off walls kindly give his advice as to the best means of getting the same off? Is there any chemical composition that would so scale it off that it would grow against the wall?—RUSTICUS.

[6818.]—**Ventilating W.C.**—Will any of your numerous correspondents inform me if an effluvia pipe from top of trap below the w.c. in my house will give the outside ventilation necessary to prevent siphoning on the closet being used, or is it necessary, in addition, to have ventilation secured at a low level lower down than the closet. This is an ordinary pan closet, and has the waste both from the bath and washbasin in same room carried into the soil pipe. The soil pipe is 4 in. diameter, and the effluvia pipe, which is carried up to the eave of house, is 1 in. in diameter.—W. H.

[6819.]—**Bones under Inn Floors.**—Mr. Thomas Blashill, at the meeting of the Institute on Nov. 21st, gave some particulars of an inn floor laid above horses' skulls, and seemed to be of opinion that the singular arrangement was for acoustical purposes. A curious discovery just made in the city of Oxford leads me to ask your readers whether there is any other reason for the association of horses' bones with the floors of hostleries. The workmen who were pulling down the premises next to the Coach and Horse, St. Giles's-road, West, found, about a foot beneath the ordinary wooden floor, a second one, the latter being constructed of leg bones of animals driven into the soil with the end upwards, after the style of the "petrified kidney" paving, so familiar to residents in Norwich. This bone floor was, however, almost as level as a billiard board, and as hard as an ordinary flag pavement. What could have been its purpose, for the acoustic theory evidently will not do?—WILL-O'-THE-WISP.

[6820.]—**Demurrage.**—In a contract lately completed under my superintendence, there is the following clause relative to the work not being executed in the time stipulated: "In failure whereof the contractor shall forfeit it and pay to the proprietor the sum of ten shillings for every day that the work remains unfinished and undelivered as aforesaid, which sum the proprietor shall be allowed to stop as liquidated damages out of any moneys due or to become payable to the contractor on account of the works." The works were not completed in the time agreed upon. My client holds on the advice of his solicitor that I, as architect, have no power in the matter, but am bound to certify less the whole sum for demurrage. The contractor holds also on the advice of his solicitor, that I am sole arbitrator, and can make allowance for any difficulties that may have impeded the execution of the work. The following clause in contract relates to my power as arbitrator: "Should any doubt or doubts arise during the execution of the works or at measuring the extras (should any occur), or at making out the accounts as to any extras in other works for which the contractor may consider he may have a claim over and above the contract price; the admission and allowance of any such claim or claims shall be judged of, determined, and adjusted solely by the architect, without reference in any way to any other person." Can your read advise me as to which solicitor is correct in his opinion, and would I be justified and secure in giving a certificate for the amount of contract and extras, with the endorsement, "This certificate is given without prejudice to any claim A. A. (client), may have against B. B. (contractor) for non-completion of the works in the time agreed upon?"—D. R.

REPLIES.

[6825.]—**Variation of Compass.**—Since inquiring through your columns as to variation of compass, I have obtained from an excellent astronomical authority (the *British Almanac* for 1881), the following list of places with their respective variations. The amounts given are all west of true North, and the variation is decreasing 9' annually. If I was correct in my remembrance of the variation in Morayshire, in 1863, being 20° 39' W., it would now be 20° 48'.

Dover	17° 43'	Scilly Islands	20° 50'
Yarmouth	17° 53'	Pembroke	21° 10'
Brighton	18° 15'	Holyhead	21° 25'
London	18° 22'	Edinburgh	21° 43'
Portsmouth	18° 50'	Glasgow	22° 30'
Portland	19° 20'	Dublin	22° 37'
Plymouth	20° 6'	Belfast	22° 55'
Sunderland	20° 16'	Cork	23° 12'
Falmouth	20° 32'	Galway	24° 5'
Liverpool	20° 49'		

This may, perhaps, be useful to some of your readers.—PETER PLAYFAIR.

[6827.]—**Breaking Weight of Girder.**—The formula for computing the breaking weight of wrought iron plate girders, when the load is in or on the centre, is as follows:— A in inches $\times D$ in inches $\times 6 = B$. W. in

tons on centre. When the load is equally distributed over entire bearing, then the girders will bear twice as much as it will when loaded in the middle. The safe load for wrought iron girders is $\frac{1}{2}$ the B. W. The letter A is the formula represents area in inches of bottom flange, including angle irons and web up to $\frac{1}{2}$ entire depth of girder. The letter D signifies depth of girder in inches,

and the number 6 is the constant for this form of girder, all these divided by 8 meaning span in feet. I have worked out the breaking weight of the girder "Inductus" draws and describes in his query, and find it to be 33 tons if loaded on centre, and 66 tons if distributed. The portion of the section crossed with the diagonal lines is included in the area of bottom flange.—ALFREDO C. HUBLEY.

gratification that an examination for young architects will henceforth be the only method of admission into the ranks of the Royal Institute of British Architects.

By the death of Mr. James Yates, J.P., D.L., of Oakwood House, Rotherham, there passes away one of the pioneers of the stove-grate and heavy casting trade in South Yorkshire. Mr. Yates expired at his residence on Saturday night, in the 84th year of his age. To the commercial world he had been known as the senior partner of the Ellingham Works (Messrs. Yates, Haywood, and Co.), Rotherham. Mr. Yates was a Liberal in politics, and nominated the late Lord Milton, M.P., at the South-West Riding election in 1865. Mr. Yates was a vice-president of the present Rotherham and District Liberal Association, and had been the president of a much older Liberal association. Mr. Yates, who has been married twice, survived both his wives. His only son was drowned at the age of eleven years, July 5th, 1841. The funeral was solemnised yesterday at noon, at the Rotherham Cemetery.

THE session of the Sanitary Institute of Great Britain was opened, on Wednesday evening, by a meeting at 9, Conduit-street, W., at which an inaugural address was delivered by Dr. Alfred Carpenter, Vice-Chairman of Council. The author congratulated the members on the position it had attained in spite of the impediments placed in its progress by older bodies, and urged that the institute could not be regarded as a rival, either to the Social Science Association, or to the societies of architects, engineers, and surveyors. One great purpose of the institute was to establish diploma examinations for sanitary inspectors, and to make examination the only entrance to such appointments. He adverted to the dangers to health incurred by taking our drinking water from sewage-polluted rivers, and predicted that some day when the temperature of the Thames was raised a few degrees above that of last summer, an epidemic would come with fearful intensity in all parts of London, except that supplied by the Kent Water Company. In the course of the evening the sealed letter accompanying the essay, to the author of which Dr. W. B. Richardson and Dr. W. Farr had awarded the prize of £200 offered by Mr. Wyatt-Edgell, formerly treasurer of the institute, was opened. The subject was "The range of hereditary tendencies in health and disease;" and twelve essays had been received. The prize was awarded to that having the motto "The subtlety of nature far exceeds the subtlety of reason." The author proved to be Mr. George Gaskin, 7, Westbourne-park, London.

On Monday last, the 5th inst., the following architects were elected diocesan surveyors for the Diocese of St. Alban's, by the Bishop, his Archdeacon and Rural Deans: Gordon Hill's, Frederick Chancellor, E. J. Dampier, J. E. K. Cutts, C. G. Vinnall, T. E. C. Streetfield. No particular portion of the diocese is given to either of the surveyors thus elected, but either may be employed at the discretion of the clergy, who are thus enabled to choose their own surveyor. Mr. Hills and Mr. Dampier were the two original diocesan surveyors who were re-elected.

CHIPS.

The Queen has accepted a copy of Mr. Fawkes' new illustrated work of reference on "Horticultural Buildings," recently published by Batsford.

The Copperhouse Wesleyan chapel, at Hoyle, West Cornwall, was reopened on Sunday week, after restoration, and the substitution of rostrum for pulpit. Mr. J. S. Hicks, of Redruth, was the architect, and Mr. Paine, of Penzance, the builder.

A new gas-holder is about to be constructed for the supply of Mold, from plans and specifications by Mr. Paterson, C.E., of Warrington.

The district of Aulsebrook, near Ashton-under-Lyne, is about to be sewered. Mr. J. C. Barton, of Ashton, is the surveyor.

The death occurred on Monday of Mr. James Mitchell, of Govan, for 44 years a prominent member of the Glasgow town council. He was mainly instrumental in carrying out the Gorbals gravitation water supply scheme, and had occupied the office of master of works for Glasgow since 1868.

A new coffee-tavern was opened in Victoria-street, Douglas, Isle of Man, on Tuesday week. Messrs. Radcliffe and Kermode, of Fiuch-road, Douglas, were the builders.

The annual distribution of prizes to the students of the Newton Abbot science and art classes was made on Friday evening, when addresses on art were delivered by the Duke of Somerset and Sir Samuel Baker.

The water was admitted on Monday for the first time into the new dock at Graugemouth, N.B., which was commenced in 1877, and is now on the point of completion. The dock proper covers an area of 11 acres, and the timber basin another eight acres. The laying of the rails round the quays is being proceeded with by the railway company, and the whole works will be opened shortly. Messrs. Charles Brand and Son are the contractors. At the same time the river Carron is being deepened to 26ft. under a contract taken by Messrs. Lawson and Best, who recently carried out the Edinburgh Docks at Leith.

The rebuilding of the tower of St. Colan Church, near St. Columb, Cornwall, which was recently carried out under the superintendence of the Rev. F. C. Hingston-Raudolph, has just been completed by the erection of a stained-glass three-light window, in memory of the late vicar. The central light is occupied by a figure of the patron saint of the church, who was a Cornish missionary, and on either side are St. Mary, patron saint of Truro, and St. Peter, of Exeter. The work was executed by Mr. Horwood, of Frome Selwood.

At a meeting of the trustees of Wells's Charity, at Cardiff, on Monday, the question arose as to the appointment of an architect and surveyor. Mr. J. A. B. Williams, the borough engineer, was proposed, to which a counter-proposition was made that Mr. James, of the firm of James, Seward, and Thomas, Cardiff, be elected. After some personal discussion, the choice was deferred for a fortnight.

The local board of Ilkeston agreed on Tuesday to purchase farming land at Little Hallum for use in sewage disposal, at the price of £1,400.

The highway board of Worral, North-West Cheshire, proceeded on Monday to the election of a district surveyor. There were 83 applicants for the appointment, the salary being £200 a year, with the obligations of keeping a horse and trap, and attending exclusively to the duties of the post. In the event Mr. T. R. Heywood, clerk of works, Wrexham, was selected, a local farmer being placed second, while the unsuccessful candidates included many borough and highway surveyors.

At the meeting on Monday of the Mountain Ash local board the very sudden death of the medical officer of health, Dr. E. W. S. Davis, was announced.

The town council of Stockton resolved on Tuesday night to instruct Messrs. Neate and Haynes, of London, to prepare plans and specifications for the proposed new bridge across the river Tees. The estimated cost is £40,000, of which half will be borne by Stockton and South Stockton.

Mr. J. Wallan, contractor, of Glasgow, was killed on the railway at Bishopbriggs, near Glasgow, on Tuesday.

The local board of St. Mary Church, near Torquay, decided on Thursday, the 1st inst., after much discussion, to purchase a site opposite the coffee-tavern, for the purpose of erecting thereon a town-hall, and to advertise for competition plans, designs, and estimates for the proposed building.

The Lieut.-Governor of the Isle of Man has proposed to follow up the new promenade improvement at Douglas, which has just been successfully completed, by the establishment in that town of winter gardens and a museum, free library and a reading-room. The proposition has been favourably received by the Manxmen, and Castle Mona, formerly the governor's residence, now an hotel, is suggested as a site.

The completion of a new mansion near Truro, to be known as Peneulnick House, was celebrated on Tuesday week by a dinner to the workmen. Amongst those present were the chief contractor, Mr. May, of Poole, the clerk of works, Mr. Thomas May, and Mr. Roberts, the builder's foreman.

The Carnarvon school-board on Monday adopted plans by Messrs. Thomas and Hughton for proposed school extensions.

The channel of the Ribble, a few miles above Lytham, having lately become so circuitous as to lengthen the course to be taken by vessels by from one to two miles, an effort is being made, by means of boards attached to chains, to control the tide so as to cause the current to reopen the channel which it has silted up with sand. The plan is devised by a Preston fisherman, named Fairclough, who has signed a contract for £100 on the "no cure no pay" system.

At a meeting of the Upper Brue District Drainage Board, held at Glastonbury last week, it was resolved to pay Mr. J. Spire, their surveyor, a salary of £100 a year.

Reopening services were held at St. Faith's Church, Maidstone, yesterday (Thursday), to commemorate the erection of a tower. It has been erected from the designs of Mr. E. W. Stephens, F.R.I.B.A., of Week-street, Maidstone, and is of Kentish ragstone, with numerous dressings of Bath stone. It has at each corner a stone pinnacle, the cornice, parapet, coping, and pinnacles being of solid masonry. The height to the top of the pinnacles is about 110ft. An addition has also been made to the vestry, with extra accommodation in the basement. It is in general character with the chancel. The contractor was Mr. Edward Vaughan, of Tunbridge-road, Maidstone, and the clock, manufactured by Messrs. Gillett and Bland, of Croydon, has three 5ft. dials.

The new Leadenhall market will be opened on Thursday next, the 15th inst., without public ceremony.

The church of St. Tendrick, at Mathern, about two miles from Chepstow, was reopened on Wednesday week, after the complete restoration of the chancel, from plans by Mr. Ewan Christian. During the progress of the work, a stone coffin, 5ft. 7in. long, by 20in. wide, and 11in. deep, external measurements, was found under the south wall; it contained bones and mould, &c., and is supposed to be that of Theoderick, King of Morgannack, who was, according to old chronicles, slain in battle against the Saxons, and buried on this spot, circa A.D. 600, when the church was founded. The contractor was Mr. William White, of Abergavenny, who has also in hand the restoration of the nave, its aisles, the tower, and porch, which are in progress, from plans by Mr. G. Pritchard, of Llandaff. The cost of the chancel restoration has been £2,500.

A bust of Grote, the historian, executed by Mr. Boehm, has just been presented to the City Liberal Club.

The Corporation of Bridgwater appointed on Friday Mr. George Laffan, of Croydon, as borough surveyor and inspector of nuisances at a salary of £200 per annum. There were nearly 100 applications for the appointment.

The workmen employed on the new town-hall at Great Yarmouth were entertained at dinner in the building one evening last week, in celebration of its approaching completion. Amongst those present were the architect, Mr. J. Bond-Peake, of Norwich, and the contractors, Messrs. J. W. and H. Lacey, of the same city.

The members of the Norfolk and Norwich Archeological Society had a day's excursion in Norwich on Thursday, the 1st inst. In the morning a visit was paid to the site of Carrow Abbey, which has been excavated by the owner, Mr. J. J. Colman, M.P. Here a descriptive paper was read by Mr. R. Makilwaine Phipson, architect, and the members afterwards visited the house on the grounds, now known as Carrow Abbey, and occupied by Mr. J. H. Tillet, M.P., which contains some Elizabethan carving. The old music-house in King-street, and several of the churches in that neighbourhood were afterwards visited.

A reredos has recently been completed for Frisby church, in Leicester, by Messrs. Jones and Willis, of Birmingham and London. The reredos proper is of alabaster, and has three panels, the centre one with the figure of our Lord in glory. The outer panels have carved cusped trefoils, with red marble columns to support caps. The side-wings are of hand-painted tiles.

It is mentioned, as illustrating the sudden increase of speculation exhibited by the applications to Parliament for the right to make new public works, that the list of new enterprises requiring Parliamentary sanction is larger than it has been since the year 1868. For 13 years there has not been such activity.

The opening meeting of the present session of the Civil and Mechanical Engineers' Society was held last (Thursday) evening at 7, Westminster Chambers, S.W., when the president, Mr. A. T. Walmisley, A.K.C., A.M.I.C.E., delivered an address.

Another mural painting for Ely Palace Diocesan Chapel, in illustration of English church history, has just been added thereto at the cost of the Lord Bishop. The subject (treated in oils) is the martyrdom of St. Alban. The grouping of the figures is specially effective, the artists being, as before, the Messrs. Powell Bros., Park-square, Leeds.

A stained-glass window of three lancet lights was last week placed over the north door of St. Giles's parish-church, Oxford. The subjects are the mustard seed, the net, and the pearl; and the work has been designed and executed by Messrs. J. Hardman and Co., of Birmingham.

The Finchley local board of health on Monday last appointed Mr. Francis James Baneroff as junior assistant in their surveyor's office. He has served the past two years in the surveyor of highways department, Islington vestry.

Wood, B. T., Hackney 8,511 0 0
Childs, C. J., Tottenham 8,400 0 0
Wheeler, W., Ravenscourt Park 8,260 0 0

*Accepted.

SPOKE ON-TABNT, STAFFS.—For supply of an ordinary steam boiler, capable of working at a maximum pressure of 60lb. per square inch, for use at the Spitals workhouse of the Stoke Union, with fittings, &c., complete:—

Hawksley and Wild, Sheffield £160 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 16, 1881.

THE FULHAM UNION INFIRMARY COMPETITION.

THE competitive designs for this Union Infirmary were at last thrown open for inspection on Saturday, and have remained on view during the present week. We are now in a position, therefore, to give our readers the results of a more detailed examination of the selected plans than we were enabled to make before, as well as a review of the other designs.

As we intimated last week, the Board of Guardians, at their last meeting, have scrupulously followed Mr. Currey's report, have awarded the respective premiums to the authors of "Experience" in Circle, and "Simplicity," and have decided that the former plan shall be carried out. There is, we hear, a strong local feeling expressed by some of the competitors, that justice has not been done. It is alleged that one of the conditions has not been strictly complied with by a certain fortunate competitor, and there seems to be a just ground of complaint, urged by some, that a few of the best plans have been overlooked, while others, which have been tinted in direct violation of the instructions, have been favourably viewed by the board. It is, perhaps, rather rigidly enforcing the instruction respecting colour, that competitors should be disqualified who have indicated the departments of their plans by different tints, yet it appears to us that if instructions count for anything, full justice is not given to those who have been careful to avoid the blandishments which, at least, attract the eye of the uninitiated.

With regard to the instruction of cost, there is also, it is alleged by some, a want of scrupulous exactness on the part of many of the competitors. One of the conditions made it a requirement that fire-proof construction was to be considered, though it is quite certain that many of the estimates have been framed at too low a price to allow for flooring on this system, and there seems to be a very wide difference between the estimates of several designs in other respects similar, ranging as they do from £20,000 to £66,700. This variation in cost has given rise to considerable discussion at the board, and it is questioned whether the selected design can be carried out for the sum named by its authors. In a few of the plans, the authors of them have not very clearly shown how the future extension of the wards can be provided, a probability which, in a fast-growing district like Fulham ought not to be disregarded. It also suggests to us the importance of sufficiently large administrative offices being provided. Some very excellent plans seem to have lost sight of this contingency in making a roadway between the workhouse and the infirmary buildings, and in crowding together the pavilions.

The plans are, generally, on the corridor and pavilion system, and most of them have placed the pavilions fronting, and at right angles to Margravine-road. There are a few notable exceptions to this arrangement, and we notice one or two very good plans which have departed from the general rule of distribution by making the short side of the land facing Fulham-road the main front.

"Experience" in Circle (Messrs. Giles and Gough), the design to be carried out, has adopted four main pavilions of wards, with a centre administrative block, connected by a corridor along the Margravine-road frontage.

Two blocks for each sex are provided, giving an excess of 24, and a third block for females is indicated as an extension. To describe more in detail this plan, we may observe that the central block has the medical officer's apartments and matron's rooms on left of the central hall, and on the right-hand the matron's office, steward's sitting-room, assistant medical officer and committee rooms. These offices form a long range in the road side of the corridors. On the south side of corridor the main administrative offices are placed, traversed by two serving corridors, one of which gives access to assistant matron's room and messroom for servants on the female side; the other corridor leads to, first, the dispensary in a convenient position near entrance, the steward's office, and to mess-room. Between these lateral corridors, and in a central position, is the kitchen, with scullery behind, and a large steward's store-room in front. Behind this block is a separate range, with washhouse and laundry. The kitchen and scullery are kept low, and are well lighted by top lights, the nurses' rooms, or cubicles, forming the first floor over the side offices. Each of the ward pavilions, 96ft. by 24ft., is of three stories and there are 32 beds shown on each floor, these being arranged in pairs between the windows on each side. A ward kitchen is provided on one side of the entrance from corridor, and a staircase and lift on the other, while projecting in front to the Margravine-road is the day-room, conveniently placed, and with its own separate store and w.c., the isolation ward being over. The bath-rooms and w.c.'s of the ward project as semi-isolated towers at the rear end, at angles; and an excellent feature is to be noticed here, adopted in some other plans, namely, a balcony for the use of convalescents in the ward, obtained between the projecting latrines. The ward is heated by two stoves in the centre. A space of 48ft. intervenes between the pavilions; there are male and female receiving-rooms on the ground-floor between each pair, and each of these has a separate entrance into corridor, and a bath and w.c. The infectious wards are placed at ends as separate pavilions, with twelve beds on the female side, and eight beds on the male side, with bath and w.c. isolated at the rear end, and a kitchen and stairs and lift near the corridor. The authors have shown a connecting-passage to the day-room in front, and the main corridors connecting these wards are provided with doors to shut them off from the other pavilions. The elevations are treated in a plain but sensible style, in brick with stone lintels and windows, and stringcourses. The connecting balconies on the upper floors are shown of a light iron construction, the administrative block having a central tower over the hall. There is much in this design to justify Mr. Currey's decision; the planning is simple and the details well studied, the open gallery allows of a free cross current between the pavilions, the subway or basement corridor for gas, water, coals, &c., in communication with the lift is well devised; the only point requiring reconsideration appears to be that the medical officers' office be placed nearer the dispensary. The estimate is £39,750, calculated at 5d. per foot;—rather a low figure.

"Simplicity" (Messrs. Young and Hall), the second premiated design, shown by a neatly-prepared set of plans coloured, follows the same general distribution, with four pavilions and end infectious wards. In the central administration block there is an entrance-hall in front, and the medical officers' apartments on the left side. The planning of the main block is, like that of "Experience," simple and satisfactory; two passages at right angles to the main one giving access to the kitchen and dispensary in the centre, and the nurses' rooms, mess-rooms, and stores on each side. The laundry,

&c., form a separate block in the rear. The kitchen, dispensary, and stores of the administrative block are only one story in height, and are top-lighted and ventilated, round which above are the bedrooms for nurses, &c. The laundry has also top-light and ventilation. The end entrance for patients is rather an objectionable arrangement.

Examining the ward arrangement, we find a very similar plan to the last—a small ward-scullery and a staircase are placed on the sides of entrances from main corridor, and a separation ward on the front side of corridor. The wards are each 94ft. by 24ft., each provides for 30 beds, which are placed in couples. At the south angles are lateral bath-rooms and w.c.'s isolated; the itch and venereal wards are placed at the extreme ends of corridor. The latter is arched with glazed openings, the blocks are three-story, and are treated in a plain style; the exterior to the administration block is rather flat and commonplace. A cart-way to the administration block is provided at the back. The estimate is £40,923.

"M.D." is a well-drawn set of plans having in composition much that is common to the two designs just described. The pavilions are placed so as to leave good spaces for light and ventilation between; and the kitchen block in the centre is shown top-lighted and ventilated; the laundry range is placed behind, isolated, and the medical offices and nurses' dormitories occupy a long narrow block in front, separated from the corridor and parallel thereto, to which it is connected by a short passage. The wards are of good proportion, but not communicable on the upper floors; the stairs are made to project on the front side of the corridor, and are made telling external features in place of the day-rooms of the plan described. These staircases in the elevation are lighted by lofty pointed windows. The separation wards are not so conveniently placed as in the former. The elevations are designed in a plain brick Gothic style with high roofs. The cost estimated is £23,500, a sum certainly below the mark.

"Plan" has also the same arrangement of wards connected by a front corridor; the administration is in the centre, and forms a long transverse block traversed by a middle corridor. Each ward of the pavilion has a kitchen and stairs on one side and an isolating ward on the other side of entrance with angle latrines, and in the centre of each ward the conveniences connected by a short isolating lobby are planned as towers placed diagonally. The end of administration block presents a rather meagre elevation to the road, and the elevations are rather commonplace. There are good points in the plan, the author of which estimates its cost at £34,000.

"South Aspect," a set of neatly-drawn plans in colour, presents the usual disposition of blocks with the infectious wards at one end; the chief difference is the broken corridor, which is recessed in front of the administration block—a plan open to the objection that it does not allow of a straight line of communication. The central administration block has a middle corridor, on one side of which are the kitchen and mess-room, with the laundry department forming a long cross range at the back, but connected. The day-rooms and isolation wards are placed on one side of the main pavilion and partly fill up the space; they have access from the corridor. The ward staircase and kitchen are in the usual position, and the conveniences project at one of the angles of ward, which is planned to hold 31 beds. We do not see the advantage of taking a roadway to the mortuary out of the area of land. The elevations are not equal in point of merit, the features have a stereotyped appearance despite the symmetrical balance and the architectural recession of the centre. The estimate is £37,317.

HOMERTON.—For alterations to entrance gates, and raising boundary wall at Homerton Hospital, for the managers of the Metropolitan Asylum District Board. Mr. W. J. Walker, architect:—
Shummar (accepted).

KING'S LYNN, NORFOLK.—For the formation and levelling of the Gaywood Marsh-road, for the Urban Sanitary Authority. Mr. John Hall, borough surveyor:—
Clare Leverington, Overton, Norfolk (accepted); T. F. Deane, Lynn; Benjamin Hubbard, Lynn; F. Hammond and Co., Lynn.

LAMBETH, S.E.—For pulling down and rebuilding 57, Biril-street, Lambeth, for Mr. W. Hart. Mr. B. Fletcher, architect:—

Buckham	2278 0 0
Cook	250 0 0
Eldridge and Gee (accepted)	220 0 0

LEEDS.—For further works in the erection of stores, cellars, &c., for Messrs. Wright Bros., at their new brewery, Leeds. Messrs. Davison, Inskip, and Mackenzie, 62, Lendenhall street, E.C., architects:—
Boothman and Son ... £345 0 0
Irwin and Co. (accepted) ... 855 0 0

LEEK.—For the erection of a large newspaper kiosk in Broad-street, Leek, for Mr. S. Rider. Mr. W. Sugden and son, Leek, architects:—

Bromage	£135 0 0
---------	-----	-----	----------

Brickwork:—

Grace	79 0 0
Hall	75 0 0
Knowles (accepted)	66 0 0

Woodwork:—

Hudson, J.	95 10 0
Tomkinson	63 0 0
Bailey and Morris	61 15 0
Hall	61 0 0
Mackrell	59 10 0
Hudson, James	55 0 0
Talton	51 5 0
Carding, H. (accepted)	38 10 0

Plumbing:—

Carding, M.	23 0 0
Stevenson	20 11 0
Johnson, T. (accepted)	19 5 6

LEICESTER.—For supply of various stores to the Corporation for the twelve months commencing Dec. 1st. Mr. J. Gordon, C.E., borough surveyor:—

Broof, R., Leicester	£150 16 1
Clarke, Nettleship and Bailey, Leicester	150 4 1
Butler, E. H., Leicester	153 3 0
Cooper and Sturgess, Leicester	151 19 1
Butler & Sons, Leicester (accepted)	145 10 8

LEICESTER.—For supply of 100 large and 40 small cast-iron gullies, with removable sludge boxes, for the Corporation. Mr. J. Gordon, C.E., borough surveyor:—

Station.	Delivered at.	Boat Yard.
Langley Mill Engineering Co., Notts.	£251 15 5	£254 7 11
Payne and Holliday, Kettering	185 15 5	187 19 7
Sharpe and Co.	180 0 0	186 0 0
Smith, Patterson & Co., Blaydon-on-Tyne	165 5 0	165 5 0
The Executors of the late D. Clarke, Carlisle	158 0 0	158 0 0
Cort and Paine, Leicester	151 2 6	151 2 6
Goodwin, Bursley and Co., Leicester	151 10 0	151 10 0
Richards and Son, Leicester	138 0 0	138 0 0
Wright, B. and E., Leicester	129 0 0	129 0 0
Jukes, Coulson, Stokes and Co., Sheffield	113 4 2	115 2 6
Mason and Co., Leicester (accepted)	101 3 4	101 3 4

LONDON.—For additions to a workshop at No. 114, Packington street, for Mr. J. Wright. Mr. F. Hill, architect:—

Hughes	£320 0 0
Grover	297 0 0
Fernley	280 0 0
Deering and Son (accepted)	290 0 0

LONDON.—For repairs, &c., to houses, Lewis-road, Streatham, and 59, Russell-square. Mr. W. Paice, architect:—

Smith, W. H. (accepted)
-------------------------	-----	-----	-----

LONDON.—For the erection of shops and offices, No. 1, Great James street, London, W.C. Mr. F. C. Notley, 3, Crooked-lane, E.C., architect. Quantities by Mr. W. Barrett:—

Bolding, A. G.	£3,792 0 0
Hayworth, S.	3,718 0 0
Payman and Fotheringham	3,623 0 0
Macey and Sons	3,632 0 0
Greenwood, J.	3,490 0 0
Langmead and Way	3,475 0 0
Lawrence, E.	3,380 0 0
Nightingale, B. E.	3,237 0 0
Axtell, J. B.	3,175 0 0
Allen, J., and Sons	3,150 0 0
Scott, S. J.	3,113 0 0

* Accepted with modifications.

LONDON.—For the supply of cast-iron to the City Commissioners of sewers. Mr. W. Haywood, engineer:—

Richards, W., Middlesborough (accepted)
---	-----	-----	-----

LONDON.—For the erection of new premises for the Birbeck Scientific and Literary Institution, Chancery-lane. Messrs. Fowler and Hill, 9, 8, present's Inn, Fleet-street, architects. Quantities supplied:—

	Portland.	Bath.

Sunpson, J. T., Fyle	...	3,687 0 0
Jackson, W. E., Fyle	...	3,615 0 0
Spoor, J., Gosforth	...	3,374 12 0
Lamb, M., Newcastle	...	2,875 15 0
Irving, J., Newcastle	...	2,795 17 0
King, C., Gateshead (accepted)	...	2,795 17 0

NORWICH.—For new bakery at the workhouse, for the board of guardians:—

Youngs, J. (accepted)	...	£212 0 0
-----------------------	-----	----------

(Lowest of nine tenders, the highest being £498).

NOTTINGHAM.—For construction of sewerage works in Red-lane and Mansfield-road, Nottingham. Mr. A. Brown, borough surveyor:—

Knight, J., Loughborough	...	£220 10 0
Cordon, W., Nottingham	...	153 12 0
Smart, T., Nottingham (accepted)	...	115 0 0

OAKHAM.—For construction of a flushing tank to main sewers. Mr. H. W. Johnson, Melton Mowbray, surveyor:—

Ingram, Oakham	...	£203 10 0
Edwards, Oakham	...	188 0 0
Barlow, Oakham	...	148 9 0
Haynes, Melton	...	145 0 0

OVENDEN.—For mason's work (labour only) required in the alteration of ashed, &c., for Messrs. S. Priestly and Son, of Grove Mill, Ovenden, Yorks. Mr. C. F. Horsfall, 1, Lord-street, Halifax, architect. Quantities supplied by the architect:—

Accepted tenders.
Mason (labour only):—
Hall, J., Halifax	...	£75 0 0

Orestwood, S., Halifax	...	213 10 0
Plasterers and slaters:—
Rushworth and Firth, Halifax	...	111 0 0

Plumber and glazier:—
Halshaw, C. A., Halifax	...	66 10 0
Ironfounders:—
Barker and Son, Todmorden	...	240 0 0

£704 0 0

PLUMSTEAD.—For alterations to oakum-picking room at the Woolwich Union, for the board of guardians. Mr. J. O. Cook, 24, William street, Woolwich, architect to the board:—

Coombs, H., Plumstead (accepted)	...	£135 0 0
----------------------------------	-----	----------

PLYMOUTH.—For Ford Church, near Plymouth. Mr. A. Norman, F.R.I.B.A., architect:—

Gill, Devonport	...	£1,687 0 0
Goodyear, Stonehouse	...	3,310 0 0
Goss, Torquay	...	3,284 0 0
Junkin, Devonport	...	3,020 0 0
Martin, Devonport	...	2,867 0 0
Feer, Plymouth	...	2,830 0 0
Dart, Plymouth	...	2,780 0 0
Blower, Plymouth	...	2,680 0 0
Finch, Plymouth	...	2,647 0 0
Lethbridge and May, Plymouth	...	2,549 0 0
Lapley, Plymouth	...	2,474 0 0
Lathorne and Goad, Plymouth	...	2,318 0 0

PLYMOUTH.—For erection of a police-station in Harbour-avenue, Plymouth. Mr. Henry Alty, C.E., borough surveyor:—

Hartley, J., Plymouth	...	£140 0 0
Foot, I., Plymouth	...	440 0 0
Parson, J. B., Plymouth	...	410 0 0
Finch, J., Plymouth	...	388 0 0
Gill, H., Plymouth	...	388 0 0
Goodyear, G. H., Plymouth	...	334 0 0
Rawlin, W., Plymouth (accepted)	...	285 0 0

POTTON.—For boundary walls, fences, gates, and the laying out of new cemetery, Potton, Beds., for the Potton Burial Board. Usher and Anthony, Bedford, architects:—

Edley and Wade, St. Neot's	...	£162 17 0
Foster, S. Kempston	...	331 0 0
Barthe, Potton	...	289 19 0
Woodman, Potton	...	256 0 0
Burnage, Potton (accepted)	...	263 5 0

RUGBY.—For the construction of the stations on the Rugby and Northampton line, for the London and North Western Railway:—
Farnell and Sons, Rugby (accepted).

SOUTHWARK.—For new hall and offices in the Southwark Bridge-road. Messrs. A. and C. Harston, architects:—

Brass	£5,110 0 0
Wall Bros.	5,050 0 0
Goodman	4,481 0 0
Hall, Beddall and Co.	4,445 0 0
Kilbey	4,470 0 0
Shummar	4,495 0 0
Crockett	3,846 0 0

SOWERBY BRIDGE.—For supply of a quantity of 12in. and 4in. pipes to the Sowerby Bridge Local Board. Mr. J. Marsland, engineer and manager:—

	12in. per ton.	4in. per ton.
Mitchell and Seddall, Sowerby Bridge	£1 15 0	5 10 0
Shorrocks, J. and R., Over Darwen	5 5 0	5 9 0
Ladlaw, R. and Son, Glasgow	5 5 0	5 5 0
Macfarlane and Co., Glasgow	5 2 0	5 5 0
Dempster, R. and Son, Elland	4 15 0	5 2 6
Newton, Chambers and Co., Sheffield	5 0 0	5 0 0
Rushforth and Thornton, Bradford	4 15 0	5 0 0
Teesdale Iron Works, Middleborough	4 17 6	4 17 6
Firmstone, C. E., Bros., Stourbridge	4 11 3	4 15 0
Jukes, Coulson, Stokes & Co., Sheffield & London	4 5 0	4 13 9
Haley, G. and W. H., Bradford	4 13 4	4 13 4
Rushworth and Co., Sowerby Bridge	4 13 4	4 13 4
Stanton Ironworks Co., Nottingham	4 6 6	4 7 6

* Accepted.

ST. PANCRAS.—Accepted for works at the vestry hall, by the St. Pancras vestry:—

Additional bookshelves.	...	£57 10 0
Steed Bros.
New matting and relaying of old.
Isom, T.	...	£23 2 0

ST. GEORGE'S, EAST.—For the supply of 100 iron bedsteads at the workhouse, for the St. George's board of guardians:—

Hawkey, R., Whitechapel-road (accepted)	...	Ss. 6d. each.
---	-----	---------------

(Lowest tender received.)

STAMFORD HILL.—For the erection of the Stamford-hill schools:—

Rawlinson, H., Tottenham	...	£10,566 18 0
Harradine, S., Gloucester road, S.E.	...	10,080 0 0
Humphreys, M. A., & Son, Tottenham	...	9,975 0 0
Morton, A., Crouch-hill	...	9,785 0 0
Harper, J., Hackney	...	9,775 0 0
Shummar, W., Lower Clapton	...	9,750 0 0
Harris and Wardrop, Woodwork st.	...	9,520 0 0
Crockett, W., St. Pancras	...	9,500 0 0
Goodman, W., Barnsbury	...	9,494 0 0
Matlock Bros., Wood Green	...	9,393 0 0
Seal Bros., Richmond	...	9,345 0 0
Higgs, J., Upper Park-lane, N.W.	...	9,330 0 0
Gardener, W., Waltham Abbey	...	9,283 0 0
Linzell, J., Tottenham	...	9,238 0 0
Perry and Co., Bow	...	9,127 0 0
Angood, J., Finsbury Park	...	9,100 0 0

* Accepted.

TORQUAY.—For alteration of galleries at Torre parish church. Mr. J. Watson, architect:—

Ireland, Torquay	...	£59 10 0
Goss, W. A.	...	56 4 7
Matthews, P., Torquay (accepted)	...	55 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 16, 1881.

THE FULHAM UNION INFIRMARY COMPETITION.

THE competitive designs for this Union Infirmary were at last thrown open for inspection on Saturday, and have remained on view during the present week. We are now in a position, therefore, to give our readers the results of a more detailed examination of the selected plans than we were enabled to make before, as well as a review of the other designs.

As we intimated last week, the Board of Guardians, at their last meeting, have scrupulously followed Mr. Currey's report, have awarded the respective premiums to the authors of "Experience" in Circle, and "Simplicity," and have decided that the former plan shall be carried out. There is, we hear, a strong local feeling expressed by some of the competitors, that justice has not been done. It is alleged that one of the conditions has not been strictly complied with by a certain fortunate competitor, and there seems to be a just ground of complaint, urged by some, that a few of the best plans have been overlooked, while others, which have been tinted in direct violation of the instructions, have been favourably viewed by the board. It is, perhaps, rather rigidly enforcing the instruction respecting colour, that competitors should be disqualified who have indicated the departments of their plans by different tints, yet it appears to us that if instructions count for anything, full justice is not given to those who have been careful to avoid the blandishments which, at least, attract the eye of the initiated.

With regard to the instruction of cost, there is also, it is alleged by some, a want of scrupulous exactness on the part of many of the competitors. One of the conditions made it a requirement that fire-proof construction was to be considered, though it is quite certain that many of the estimates have been framed at too low a price to allow for flooring on this system, and there seems to be a very wide difference between the estimates of several designs in other respects similar, ranging as they do from £20,000 to £66,700. This variation in cost has given rise to considerable discussion at the board, and it is questioned whether the selected design can be carried out for the sum named by its authors. In a few of the plans, the authors of them have not very clearly shown how the future extension of the wards can be provided, a probability which, in a fast-growing district like Fulham ought not to be disregarded. It also suggests to us the importance of sufficiently large administrative offices being provided. Some very excellent plans seem to have lost sight of this contingency in making a roadway between the workhouse and the infirmary buildings, and in crowding together the pavilions.

The plans are, generally, on the corridor and pavilion system, and most of them have placed the pavilions fronting, and at right angles to Margrave-road. There are a few notable exceptions to this arrangement, and we notice one or two very good plans which have departed from the general rule of distribution by making the short side of the land facing Fulham-road the main front.

"Experience" in Circle (Messrs. Giles and Gough), the design to be carried out, has adopted four main pavilions of wards, with a centre administrative block, connected by a corridor along the Margrave-road frontage.

Two blocks for each sex are provided, giving an excess of 24, and a third block for females is indicated as an extension. To describe more in detail this plan, we may observe that the central block has the medical officer's apartments and matron's rooms on left of the central hall, and on the right-hand the matron's office, steward's sitting-room, assistant medical officer and committee rooms. These offices form a long range in the road side of the corridors. On the south side of corridor the main administrative offices are placed, traversed by two serving corridors, one of which gives access to assistant matron's room and messroom for servants on the female side; the other corridor leads to, first, the dispensary in a convenient position near entrance, the steward's office, and to mess-room. Between these lateral corridors, and in a central position, is the kitchen, with scullery behind, and a large steward's store-room in front. Behind this block is a separate range, with washhouse and laundry. The kitchen and scullery are kept low, and are well lighted by top lights, the nurses' rooms, or cubicles, forming the first floor over the side offices. Each of the ward pavilions, 96ft. by 24ft., is of three stories and there are 32 beds shown on each floor, these being arranged in pairs between the windows on each side. A ward kitchen is provided on one side of the entrance from corridor, and a staircase and lift on the other, while projecting in front to the Margrave-road is the day-room, conveniently placed, and with its own separate store and w.c., the isolation ward being over. The bath-rooms and w.c.'s of the ward project as semi-isolated towers at the rear end, at angles; and an excellent feature is to be noticed here, adopted in some other plans, namely, a balcony for the use of convalescents in the ward, obtained between the projecting latrines. The ward is heated by two stoves in the centre. A space of 48ft. intervenes between the pavilions; there are male and female receiving-rooms on the ground-floor between each pair, and each of these has a separate entrance into corridor, and a bath and w.c. The infectious wards are placed at ends as separate pavilions, with twelve beds on the female side, and eight beds on the male side, with bath and w.c. isolated at the rear end, and a kitchen and stairs and lift near the corridor. The authors have shown a connecting-passage to the day-room in front, and the main corridors connecting these wards are provided with doors to shut them off from the other pavilions. The elevations are treated in a plain but sensible style, in brick with stone lintels and windows, and stringcourses. The connecting balconies on the upper floors are shown of a light iron construction, the administrative block having a central tower over the hall. There is much in this design to justify Mr. Currey's decision; the planning is simple and the details well studied, the open gallery allows of a free cross current between the pavilions, the subway or basement corridor for gas, water, coals, &c., in communication with the lift is well devised; the only point requiring reconsideration appears to be that the medical officers' office be placed nearer the dispensary. The estimate is £39,750, calculated at 5d. per foot;—rather a low figure.

"Simplicity" (Messrs. Young and Hall), the second premiated design, shown by a neatly-prepared set of plans coloured, follows the same general distribution, with four pavilions and end infectious wards. In the central administration block there is an entrance-hall in front, and the medical officers' apartments on the left side. The planning of the main block is, like that of "Experience," simple and satisfactory; two passages at right angles to the main one giving access to the kitchen and dispensary in the centre, and the nurses' rooms, mess-rooms, and stores on each side. The laundry,

&c., form a separate block in the rear. The kitchen, dispensary, and stores of the administrative block are only one story in height, and are top-lighted and ventilated, round which above are the bedrooms for nurses, &c. The laundry has also top-light and ventilation. The end entrance for patients is rather an objectionable arrangement.

Examining the ward arrangement, we find a very similar plan to the last—a small ward-scullery and a staircase are placed on the sides of entrances from main corridor, and a separation ward on the front side of corridor. The wards are each 94ft. by 24ft., each provides for 30 beds, which are placed in couples. At the south angles are lateral bath-rooms and w.c.'s isolated; the itch and venereal wards are placed at the extreme ends of corridor. The latter is arched with glazed openings, the blocks are three-story, and are treated in a plain style; the exterior to the administration block is rather flat and commonplace. A cart-way to the administration block is provided at the back. The estimate is £40,923.

"M.D." is a well-drawn set of plans having in composition much that is common to the two designs just described. The pavilions are placed so as to leave good spaces for light and ventilation between; and the kitchen block in the centre is shown top-lighted and ventilated; the laundry range is placed behind, isolated, and the medical offices and nurses' dormitories occupy a long narrow block in front, separated from the corridor and parallel thereto, to which it is connected by a short passage. The wards are of good proportion, but not communicable on the upper floors; the stairs are made to project on the front side of the corridor, and are made telling external features in place of the day-rooms of the plan described. These staircases in the elevation are lighted by lofty pointed windows. The separation wards are not so conveniently placed as in the former. The elevations are designed in a plain brick Gothic style with high roofs. The cost estimated is £23,500, a sum certainly below the mark.

"Plan" has also the same arrangement of wards connected by a front corridor; the administration is in the centre, and forms a long transverse block traversed by a middle corridor. Each ward of the pavilion has a kitchen and stairs on one side and an isolating ward on the other side of entrance with angle latrines, and in the centre of each ward the conveniences connected by a short isolating lobby are planned as towers placed diagonally. The end of administration block presents a rather meagre elevation to the road, and the elevations are rather commonplace. There are good points in the plan, the author of which estimates its cost at £34,000.

"South Aspect," a set of neatly-drawn plans in colour, presents the usual disposition of blocks with the infectious wards at one end; the chief difference is the broken corridor, which is recessed in front of the administration block—a plan open to the objection that it does not allow of a straight line of communication. The central administration block has a middle corridor, on one side of which are the kitchen and mess-room, with the laundry department forming a long cross range at the back, but connected. The day-rooms and isolation wards are placed on one side of the main pavilion and partly fill up the space; they have access from the corridor. The ward staircase and kitchen are in the usual position, and the conveniences project at one of the angles of ward, which is planned to hold 31 beds. We do not see the advantage of taking a roadway to the mortuary out of the area of land. The elevations are not equal in point of merit, the features have a stereotyped appearance despite the symmetrical balance and the architectural recession of the centre. The estimate is £37,517.

"Quod Petis Hic Est," the design of local architects, has many good features, based upon the Herbert hospital. Unlike the other competitors, the authors have connected the pavilions by a corridor near the south boundary, by which means a good garden is obtained between each pair of blocks, besides a yard on the south side of corridor. The plan shows the isolation wards at the south end of wards, and convalescents can thus enjoy a good aspect. The wards provide for 628 patients. The details of the administrative department have been carefully worked out, and indicate a practical acquaintance with infirmary buildings. In the centre, after passing the medical superintendent's offices, a roadway gives access to the steward's and assistant medical officers' rooms on each side, near which is the receiving ward. At the end of this roadway is a tower carried up for a water-tank to work hydraulic lift, and right and left are the main connecting corridors. By the arrangement all new applicants can be quickly examined and sent into any particular ward. The laundry is placed behind the ward pavilions have a distance of 60ft. between, and a wide garden is obtained between the centre administrative block and the pavilions. The infectious wards are at the ends. The estimate is £55,000, and room for two additional pavilions is indicated.

"Hôtel Dieu" is a plan which has been favourably considered; the general principle of the corridor and pavilions has been followed. The matron's, steward's, medical officers' rooms are well placed in the centre, in connection with the front corridor, and occupy a long front building between the two centre pavilions and in front of corridors. The mess-rooms are behind, and the kitchen is in the centre, with the laundry department attached in the rear. In the wards, the separation-rooms are placed in front of corridors, and the day-room between entrance and ward proper, occupying, in fact, a part of the pavilion. Each ward provides for 20 beds, and there is a space of 75ft. between the pavilions; it has a foul-linen shoot at the end, with well-arranged lavatories and bath-rooms. The basement plan shows coal-stores under all the blocks, an expensive and unnecessary provision. The elevations are drawn in a Renaissance style; the centre block is marked by a tower, with high concave roof, and these features are repeated at the ends, and at the pavilions.

"Experience" in Oblong, is a clever arrangement. The administration block faces the Fulham-road, and a roadway on the south side is shown, giving access to the several pavilions, which are connected by a corridor also on this side. Both infectious wards are placed at the east end, separated by a wall from the other blocks. The day-rooms are on one side of wards, the nurses' room with inspection window, the scullery, bath-room, and w.c.'s forming a corresponding projection on the other side. Good provision is made for separation of cases, the foul linen is separated from the main wards, and the kitchen offices are only one story high. On the other hand, the pavilions look rather crowded together, there is a distance of 50ft. between them. The elevation is rather hackneyed, but the author by this arrangement has considerably reduced the cost by avoiding a long frontage towards Margrave-road. The estimate is £39,835.

"The House of the Poor and the Sick" is a coloured plan, showing the pavilions placed lengthwise of the land with a centre administrative department, the infectious wards being at the end. The plan is hung too high to admit of inspection, but from a general glance some ingenuity is seen to be evinced in the planning.

"Apropos" is the motto of a well-drawn set of plans; the pavilions have circular angle towers or latrines in the rear; the

front elevation is neat, the Classical treatment of the centre block and the pavilion ends being made features. Here the infectious wards are objectionably placed behind the centre administration block, but the general planning and details of the wards and official apartments are meritorious.

"Experience" departs from the beaten track; the wards or pavilions have return end wings, and are connected by a central corridor to a middle administration block, the infectious wards being at the ends. We doubt the desirability of right-angle wards, as the spaces enclosed would be comparatively shut out from sunlight. The isolation wards and kitchens are cleverly arranged at the intersection of the corridor.

"Desideratum" is a well-considered plan in its main features. We rather object to the position of the day-room, which is placed between each pair of pavilions, and is entered separately from the corridor; also the medical superintendent's house at the back of the administration block. In other respects it follows the generally accepted arrangement. The stores for bedding are placed under the isolation wards, which project in front of the main corridor. There is a useful balcony shown for invalids' use between the circular turrets of bath-rooms, and w.c.'s at the south end of each ward.

"Economy" has a long row of administration offices in the centre, the wards appear to be generally well proportioned and provided, and the medical superintendent's residence is in the front part of the administration building, and in a good position. The elevation is drawn with Queen Anne features. "Sanitas" arranges the wards on a different plan to that generally adopted. Each block contains two wards. The beds are ranged on each side of partitions in a wide ward, on a principle followed in some of the Union infirmaries. A centre corridor connects the two blocks, one for each sex, with the central offices. The isolation wards and kitchens are well disposed. The elevation is in a Gothic style, rather meagrely treated. "Beacon" has a symmetrically and generally well-disposed arrangement; the treatment is Gothic, and the elevation is good. We may also mention "Spes" in star, showing six pavilions and a complicated set of offices; "Sic Omnes," a rather ill-digested plan, with the isolation wards at the further ends of each block, an undesirable position. "Albion," "To Be, or Not to Be," "Samaritan," "Fit," and "Observance," "L'Esperance," "Home of Plenty," "Fortuna Sequator," are designs, which have not met the requirements so fully as those we have described, though their authors have spared no pains. We are sorry more room was not given to the exhibition of these sets of designs, which comprise, on the whole, a large number of detail drawings, many of which are hung so high as to make examination difficult or quite impossible. The competition shows a large amount of talent, and the labour expended in some of the designs is considerable. It is satisfactory to find the board have acted in strict accordance with the referee's selection.

THE BRIGHTON HEALTH CONGRESS AND EXHIBITION.

THE Domestic and Scientific Exhibition now open at the Royal Pavilion, Brighton, is a collection of a somewhat miscellaneous character, in which the local manufacturers and shopkeepers are largely represented. The domestic and sanitary exhibits are numerous, and of a generally interesting kind, and include many appliances by well-known firms. In the Corn Exchange, a hall having an old and unique timber roof of an elliptical form, we meet with the names of several well-known manu-

facturers. One of the first compartments we come to is occupied by S. Hannington and Sons, of Brighton, and is furnished in an artistic manner, with a suite of drawing-room furniture in rosewood and satin. The chimney-piece and cabinet are designed in a quiet Louis XVI. taste, and the colouring of walls and upholstery is in pleasing harmony. Russell R. Perry, of Brighton, has been successful also in the choice of his fabrics. The "Lincrusta-Walton" decorations deservedly attract notice for their design and colour. In addition to a few select samples of wall-decorations in Jacobean and the Adams styles, we have pleasure in noticing a new application of this material as panels for doors, cabinet furniture, and wall-linings. These hand-painted panels of the material can be fitted to any size of panel, and are very effective as well as inexpensive and durable. The silk-imitation tapestries in paper are another novelty introduced by this firm, and some of them represent rich embroidery patterns on a subdued satin ground. Specimens of parquetry, by Eberhard, laid in his patent composition glue, are on view, and the facility with which the parquet can be laid on brick or stone and cement floors claims attention. Passing Sendall and Son's (Brighton) very cleverly imitated woods and marbles, we note a show of dado and wall-papers manufactured by Woolmans and Co., of London, remarking especially some embossed, light leather-papers, in good patterns and tints; also the embossed flock papers, a speciality of this firm. All the papers are free from arsenic. Further on we see a handsome stand filled with Doulton and Co.'s Lambeth faience, consisting of vases and plaques; some beautiful specimens of Doulton ware, *pâte-sur-pâte*, impasto, tiles, decorations, &c. Art needlework is represented by a few stalls of local artists. W. Kemp exhibits a few examples of altar frontals, stoles, and other ecclesiastical embroidery; Maria Hatch some specimens of *appliqué*.

We give a glance at Howard and Sons' (Berners-street) parquetry flooring. Bishop and Son, Marylebone-road, show at the end of hall a two-manual chancel organ of pitch-pine, the pipes being designed by C. H. Nisbett, and the upper part or works being made to project considerably over the key portion. Mr. W. Watt, of Grafton-street, W., exhibits some art furniture; C. Feldwick and Sons, Brighton, have a unique, dark mahogany Chippendale cabinet, with a pagoda top, for china, particularly worth notice. In the class of Decorative art, we make notes of various stalls in which painted china is shown, and various local lady exhibitors (39 to 56) are chiefly represented. We notice a few terra-cotta plaques decorated with apple blossom and other flowers, a painted Lincrusta screen (43). The Art Tile, China, and Glass-painting Co., of Finsbury-pavement, are exhibitors of specimens of stained and painted glass. The Albissima Paint Co., Lime-street, E.C., has a conspicuous stand, which forms a canopy structure at one end of the hall, and is, in itself, high testimony of the purity and opacity of the white which is manufactured by the company. Their sanitary paint has all the advantages of the ordinary white-lead, but devoid of its poisonous qualities; it has a good covering power, and for the painting of ships and decorative purposes generally is well adapted. The specimens show its capabilities for covering and mixing with pigments; and the tubes which are prepared for artists are an excellent substitute for the whites generally used.

The architectural drawings in ink and colour occupy one compartment of the Corn Exchange, and are almost entirely those of works of local architects. The remark we made respecting the charge made by the

Committee for wall space in this department has been fully borne out by the result, and a larger collection of drawings by good men would have been forthcoming in all probability if architects had been placed on a different footing, and their works invited. Mr. T. W. Cutler, F.R.I.B.A., shows an exterior in ink of a tile-hung and timber house with a corner bay. Mr. Edmund E. Scott (Scott and Hyde, architects, of Brighton), contributes a sepia drawing of some quietly-handled Gothic schools for Baroness Burdett-Coutts in Rochester-row, also an ink drawing of a house to be built in Sussex, having a picturesque and simple gable treatment, with a tower, the upper part of the house being tile-hung. The water-colour interior of St. James's Church, Brighton, showing brick and stone arcading, is cleverly executed. We also note a classroom, Cliftonville, shown by an ink drawing by Holford, Clayton, and Black, architects, of Brighton, and perspective view of shops at Redhill, well drawn in ink, with a gallery above the shops. Mr. T. W. Cutler exhibits an ink perspective and plan of a memorial cottage hospital, at Eastbourne, with details of the ward fireplace, hollow walls, and ventilating flues; drawings of a cottage and studio in Berkshire, interior of billiard-room, &c. Mr. W. Emerson has a view of St. Mary's Church, St. James-street, illustrated by us, and an interior view in colour; besides an effective water-colour drawing of an Indian college at Allahabad University. Mr. John G. Gibbons, of Brighton, sends a drawing of school of art on the Grand Parade; and Messrs. Lainson and Sons, an ink view of the Alexandra Hospital, Brighton—a building of Renaissance design, besides a drawing of the Reading Town-hall, which we have given, and of premises at the corner of West-street. Mr. Somers Clarke, jun., has a large sepia interior view of St. Martin's Church, Brighton, and the pulpit and canopy in the same church. Mr. Rowland Plumbé, F.R.I.B.A., is represented by several ink drawings: among the chief we notice a church at Woodford Green, drawn in ink; an interior of a billiard-room, Kilburn; a house at Surbiton, Gothic half-timbered; a hall and theatre, Hampton-wick, showing a timber roof; and a board-school at Walton-on-Thames, simple in grouping. Mr. J. Pitt Bayley, of London, is an exhibitor of several designs for churches.

The other exhibits in the Corn Exchange comprise various food-products, beverages in the form of mineral and aerated waters, pancreatine, peptonised milk, &c. The sanitary and domestic appliances located in the iron annexe are comprehensive in their variety. We notice amongst the leading appliances in this department the "adjustable desk" manufactured by Colman and Glendinning, and shown by the North of England School Furnishing Co., Darlington, besides various improved chairs, art tables, and school desks, complying with hygienic principles. The "euthermic gas-heating stove," shown by E. G. Benford, Castle-square, we have already favourably spoken of; also the ventilating gas-bracket, gas-burners, &c., all of which are the inventions of Dr. Bond. The patent pyrogen, for raising fires quickly, is an ingenious appliance. Hill's patent bars for kitcheners are noteworthy; and we must not pass by the walnut chimney-pieces, showing the smoke-consuming and slow-combustion grate of Fred. Edwards and Son, Marlborough-street, London, the construction of which we have lately described in referring to the Smoke-Prevention Exhibition at Kensington. Davis and Co., Camberwell-road, have on view one of their economical gas-stoves, the "Metropolitan" gas kitchener; and in this branch we notice several local firms: C. Green (178), Packham and Co.—the latter of whom have a large kitchen-range handsomely fitted with blue tiles, and a new

assortment of Ritchie's heating-stoves, &c. T. Walter and Co., of Southwark, have a useful display of heating and sanitary appliances. J. H. Gardener, West Brighton, is a large exhibitor of chimney-pieces and ironmongery; Hindmarsh and Co. have a large show of ranges, baths, grates; and Reed and Sons (183) some good smoke-consuming stoves, lavatories, &c.

Charles Drake and Co. (189), Battersea Park, whose concrete specialities we have often referred to, exhibit, among other things, a patent mosaic marble bath, pavements, table top, and chimney-piece. The jointless pavement shows the capabilities of this material. The slab-faced concrete wall, the fireproof tread and riser, and floors are well worth the attention of architects and others. F. H. Tuxford, Brighton, shows a model of house drainage and a new basin and trap combined, also an improved O-lead trap, intended to make repair more easy. In the same class of objects must be mentioned the sanitary exhibits of John Coley Bromfield, of Brighton. The "Sanitary carbon" samples are interesting, and the silicate oxide substitute for lead-paint deserves mention. Mr. Alfred Bedborough, architect, Abingdon-street, is the exhibitor of a patent "Imperial" window for ventilation, in which the difficulties and dangers attending the ordinary sash-window are obviated. The Imperial window has top and bottom sashes, but the top sash and frame are made 12in. more in height, the frame or casing running up above the window soffit. By this increased length the sash can be lowered to allow for ventilation, the space between the two insuring a vertical current of air. The upper 12in. is divided into smaller panes. Another special point to notice is a method of grooving the outside lining of the sash frame, by which means draught and dust are excluded. One of the models shows how an ordinary sash window may be made to revolve on centres for cleaning, and the cost, we are informed, is only about 16s. a window.

The "Eureka Concrete" Company send a concrete culvert or sewer of large section, made of their concrete; also samples of paving and flooring, lintels, the "Gas detector," invert blocks, and moulded steps of excellent manufacture, showing great hardness and strength. Hayward Bros., Queen Victoria-street (188), have a window fitted up to show their patent semi-prismatic pavement lights, and the result of the trial will convince the most sceptical of the value of these light concentrators and directors, already favourably known to the profession. The specimens of coal-hole plates for ventilation and the foothold given in these are great improvements upon the old plates, which have caused many serious accidents. H. Sharp Jones and Co., Poole, Dorset, exhibit large tubes made in their "rock concrete," and the roofing tiles and Wright's indestructible fixing blocks to substitute for wood bricks in fixing joinery, are worth the attention of architects. Uriah Clark, Sussex, has a variety of terra-cotta ridge-tiles, finials, and other ornamental accessories, and we also notice R. and H. Norman's red facing bricks (187). R. Adams's safety-sliding windows, with flexible brass tongues hung on centres, the spring-door check, and other appliances for opening and adjusting windows and fanlights, are well worth examination.

We must notice briefly the "Imperial stone" exhibits of Hodges, Butler and Dale, East Greenwich. This silicated stone is made into sewers, paving, steps, coping, edgings, sewer-inverts, and every form of detail used in building and sanitary works. The enamelled bath made of this stone is interesting as showing the general use of the material. A few other objects in this part claim our notice. Kaye's patent indestructible locks and furniture; Hanson and

Co.'s self-acting engine for chemical precipitation processes; drawings of the Artisans', Labourers', and General Dwellings Company for houses of several classes, designed by Mr. Rowland Plumbé, and the plans and drawings exhibited by the Improved Industrial Dwellings Company (247).

Referring to some of the chief sanitary appliances, we must notice the large stand of Messrs. Doulton, in which are a large display of that firm's closets. The valve-closet, with stoneware trap, and the vacuum waste preventer, and "wash-out" closet, and the trapless closet, are certainly effective sanitary apparatus, and we note the automatic flush tank, for drains, non-concussive valves, radiating tile stoves, &c.

F. G. Underhay (238) has a collection of urinals, lavatories, &c. The automatic urinal basin, which siphons out at every fill, is a clever and cleanly form of apparatus, and the basin-valve exhibited has the merit of quickly discharging. We also glance at the admirable automatic electric speaking-tubes and appliances shown by G. Jennings, the improved copper bath and tip-up basins, slop-sinks, and an excellent and simple automatic cistern for flushing, shown by D. T. Bostel (236). Maguire's safety-joint drain and flushing tank are worthy of attention. R. Boyle and Sons (219) have a large stand of their well-known and tested air-pump ventilators. Among the improvements made by this firm we note especially a new chimney-cowl to prevent draught, a railway-carriage ventilator, and an inlet for heated air consisting of a small coil of copper pipe heated by a gas-jet at the inlet end of tube. Messrs. Kite and Co. are also exhibitors of their exhaust ventilators for roofs and smoke-curing chimney caps to which we lately referred; and Banner Bros., of Billiter-square, have a number of interesting models illustrating their system of sanitation applied to houses and public buildings, the chief merits of which we have discussed before in these pages. The Birmingham Sanitary Association exhibit Pott's Edinburgh air-chambered sewer-trap, and Emanuel and Sons a siphon waste preventer and improved closet-regulator.

Among the heating appliances we must call attention to the Treasure stove in operation, manufactured by T. J. Constantine, which we described a week or two since, Bardon and Perkins' steam cooking-apparatus, and the visitor, finishing his perambulation of the iron annexe, will not fail to be interested in the iron hospital fitted up by J. C. Humphreys (254), with models of hospital beds and patients, nor the range of iron buildings which have been erected for the exhibition annexe.

The other departments of the exhibition in the Royal Pavilion comprise a valuable loan collection, chiefly from the South Kensington Museum, objects from the Indian Museum, and several coloured drawings, all especially interesting. We must also notice the electric apparatus, post-office telegraphs, &c. The Health Congress was opened on Tuesday evening by the President, Dr. B. W. Richardson, who delivered an inaugural address in the dome, in which he dwelt chiefly on the physical and hygienic training of children. The health of towns, including sanitary legislation, has been discussed under section A, over which Mr. Edwin Chadwick, C.B., presided. Reform in slaughter-houses, by H. F. Lester, B.A., and discussions on the subject; and various papers and discussions on cheap foods, preservation of food by cold, bread reform, formed the subjects of the sectional meeting yesterday (Thursday). In the discussions, Dr. C. Drysdale, Mr. Lightfoot, Mr. Winter Blythe, medical officer of health, Marylebone, took part. Section C. opens to-day, and will include an opening address by Dr. A. Carpenter, after which domestic sanitation, filtration, smoke prevention, &c., are to be discussed, including

a paper by Robert Edis, Esq., F.S.A., on "Sanitation in Decoration."

ROYAL ACADEMY DISTRIBUTION.

ON Saturday, Dec. 10th, being the one hundred and thirteenth anniversary of the foundation of the Royal Academy, the distribution of medals and prizes took place in the large gallery before a numerous assembly. There was more than usual interest this year in the proceedings, not only because of its being what is known as a "Gold-medal year," when the rewards are of greater value, and the ceremony is enhanced by the reading of the President's address, but in consequence of the great increase in the number of prizes, and their value. We referred to this some time ago when giving a description of the new laws and regulations of the Academy. The Gold Medal and Travelling Studentship for each of the sections have been thrown together, and the latter augmented to £200, and between £300 and £400 more money is given in prizes. There were over two hundred competitors for the forty-two prizes offered, three or four of the latter, however, not being awarded. The President, Sir Frederick Leighton, on taking the chair, stated that, as he would deliver a speech, according to the usual custom, after the distribution, he would confine himself to a few remarks on the standard of the competitive work, which, he was glad to say, was above the average, particularly in the paintings submitted for the historical painting, and the paintings from the life. In some cases, he said, the members of the Academy had not thought the works up to the proper standard; and, therefore, they had withheld the rewards. But it must not be thought, on that account, that they were destitute of merit.

The following is a list of the awards, and the successful competitors:—

Gold Medal and Travelling Studentship of £200, tenable for one year, for an historical painting, subject, "The Messengers Coming to Job" (cf. Job I.), Samuel Mellon Fisher. Five competitors.

Turner Gold Medal and a scholarship of £50, tenable for one year, for a landscape painting, subject,

"Light thickens, and the crow
Makes wing to the rooky wood;
Good things of day begin to droop and drowse,"
M. J. H. 2.

Bryan Hook, the second son, we believe, of the Academy.

Travelling Studentship of £200, open to gold medal student only. One competitor. Not awarded.

The Grosvenor Prize of £50, for a landscape painting in oil, subject, "Ashby Lane." Five competitors. Prize, Marzani Hickson.

Painting of a Figure from the Life. Twelve competitors. 1st medal, Horace B. Fisher; 2nd medal, George Bull.

Painting of a Head from the Life. Nineteen competitors. 1st medal, James E. Bieun; 2nd medal, Bernard Evans Wood.

Copy of Oil Painting. Seven competitors. Silver medal, J. E. Bieun.

Silver Medal for Copy of a Landscape. Three competitors. Not awarded.

Silver Medal and £25 for Cartoon of Draped Figure. Not awarded.

Amateur Prizes for a Design in Monochrome for a Figure Subject. Twenty-two competitors. Prize of £30, W. Grafton-Bagen; of £10 to J. L. Davis.

Design in Water-colour for the Decoration of a Portion of a Public Building. Subject, "An Allegorical Illustration of Painting." Two competitors. Prize of £10 to H. M. Paget.

Drawing of Figure from Life. Twenty-nine competitors. 1st medal, Bernard Evans Wood; 2nd medal, A. W. Hayes.

Set of six Drawings from the Life. Twelve competitors. 1st prize of £50, Thomas C. Benham; 2nd prize of £25, William Carter; and prize of £15, W. M. Loudoun; 4th prize of £10, W. Grafton-Bagen.

Drawing of Head from the Life. Thirty-four competitors. 1st medal to Horace B. Fisher; 2nd medal, W. Grafton-Bagen.

Design of a Statue or Group. Seven competitors. 1st prize of £50, John Noyes; 2nd medal not awarded.

Design of a Statue or Group executed within the Year with a Medal. £10 prize to Theodor John Noyes.

Perspective Model (Architects). No competition.

Gold Medal and £25 for a Line Engraving. No competition.

Gold Medal and Travelling Studentship of £200 for a competition in sculpture. Subject, "David Wrestling with the Angel." Four competitors. Prize, Oscar A. Rees.

Medal for a Round. Five competitors. 1st prize of £25, J. Wade; 2nd prize of £10, A. G. Atkinson.

Design for a Medal in Plaster. Subject, "Hercules Slaying the Stymphalian Birds." On the reverse a statue of Hygeia. One competitor. Silver medal. Susan Ruth Canton.

Model of Figure from Life. Two competitors. 1st medal, Dant J. Wade; 2nd medal not awarded.

Model of a Statue or Group. No competition for the medal or £10 premium.

Gold Medal and Travelling Studentship of £200, for a Design in Architecture. Subject, "A Casino or Club for an Inland Watering-Place." Five competitors. Prize, James Howard Ince.

Measured Architectural Drawings. Subject, "Stone Church, Kent." Four competitors. 1st medal, W. Bassett Smith; 2nd medal, Thos. C. Yates.

For the Best Design executed in the Upper School. Prize of £25 to W. R. Lethaby. Four competitors.

For the Best Design executed in the Lower School. Two competitors. Claude Pemberton Leach.

Perspective Model (Architects). No competition.

Commencing our description with those competitive works in which our readers would be most interested, the subject for the Gold Medal and Travelling Studentship was "a casino or club for an inland watering-place," the principal accommodation to consist of a large concert-hall, a small theatre, dining-room, café, reading-room, card-room, and other offices, with arcades and balconies, and a garden or court in front 100ft. in depth; the main building to measure about 250ft. by 200ft., with garden or tennis-courts on the other three sides. The design to which the Gold Medal and Travelling Studentship was awarded, bearing the motto "Kismet," is by Mr. J. Howard Ince. He places the concert-hall on the ground-floor, facing the gardens, the theatre at the back forming the right wing, and the dining-room opposite; between the two is an open court attached to the café. The position of the concert-hall is not quite happily chosen, because he restricts the prospect of the garden to the frequenters of that hall, who may stroll from thence to the arcade or galleries above, which he provides. Concerts being generally given in the evening, its especial value is lost; and the dining-room and café, which should have been placed on this side, are the chief losers. It has, however, possibly suggested a feature which is the prettiest part in the design, thoroughly in harmony with the destination of the building, and good in style—viz., the open court of the café, with a pavilion in the centre for musicians. Mr. Ince is the only one who provides a covered front for carriages—an obvious necessity in a climate like ours for those attending the concerts, balls, and theatrical entertainments. Unfortunately, there is only one such carriage porch, so that if a concert or ball and theatrical performance happened to take place at the same time there would be sudden confusion. The access from thence to the concert-room is difficult, and the use of the news-rooms as an ante or cloak-room to the concert-hall quite unfeasible.

The perspective and elevations are of Late Gothic character, the carriage porch and tower being picturesquely grouped at one end. In this design, as in most of the others, the first object which the competitors seemed to have striven for is *picturesqueness*, and this has been arrived at only by utter disregard of the requirements of the plan or character and suitability in the elevations; in fact, Sir Frederick Leighton, in his opening address, remarked that the competitors did not seem to have tried to suggest the destination of the building by the details or design of their architecture. Mr. Ince's design looks more like a middle-class school or college library, and it is only in his open café that he has caught the spirit of his subject. The drawings are beautifully executed, and we congratulate Mr. Ince on his success, especially as we remember he came in second in the Gold Medal competition two years ago.

The design sent in under the motto "Mirth" is also Gothic, freer perhaps and more florid in design, but still without any special character belonging to a casino. The author places his chief entrance on the garden side, the reading-room on the right,

with the theatre in the rear, the dining-room on the left with the café in the rear. The principal staircase is beyond the vestibule, and leads to concert-room on the first floor over dining-room and café. There is a special staircase for the theatre. The section shows billiard-room and card-rooms on an upper floor, so that, as may be imagined, the building is an extremely lofty one. What might have been useful space in the vestibule is occupied by the thick walls of a useless tower, which rises some 200ft. from the ground—a fine and conspicuous object in itself, but out of character with the building, and a very expensive luxury for the few people who would care to ascend it. The front is picturesquely grouped, but wanting in repose; the concert-room is much over-lit, so that if there had been only one window on the narrow side, and a little more plain wall surface with characteristic decorative sculpture, the design would have gained. The upper portion of the central part is much better in this respect; though, again, we require something to suggest the destination of the building—figures and decorative sculpture, such as, for instance, a precedent might have been found for in the Musicians' House at Rheims. The same remark we have made relative to the fenestration of the concert-hall applies to the right wing: there are too many windows. The drawings are extremely artistic in their execution, and show considerable freedom and ease in design.

"Per Lapsus in Ardua." With the exception of the large corridor in the centre of the building, which is badly lighted and comparatively useless, the plan of the design submitted under this motto has many good points. The café, news-room and reading-room all face the garden, with an open arcade running in front of them. The entrance is in the centre at the back, with vestibule and staircase leading to the concert-room, which is placed on the first floor, and forms the principal feature of the elevation, so that, at once, a certain character is given to the building. It is rather difficult to determine the precise style: the two gables on the extreme right and left wings belong to the period of the First French Renaissance, the windows of the concert-hall remind us somewhat of St. James's Hall. There is a distinct attempt, however, to suggest the destination of the building by the style adopted; but more acquaintance with it, and much more study, would be required to make the result quite satisfactory.

"Celeriter" does not seem to accord with the programme. A large concert-hall and small theatre was asked for; whereas the reverse has been provided by the author of this design. The motto seems too indicative of the want of time required for the study of the design, which has no special character, and is not characterised by the careful drawing to be found in his fellow competitors' works.

"Backalun." The author of this design is the only one who has frankly adopted the Classic style, with many of the deceptions generally ascribed to the style, not however inherent to it, or necessary for its conception. The masking of the concert-hall, which ought to have formed the central feature as in the set marked "Per Lapsus in Ardua," has reduced the design to commonplace, which is not relieved by the clever draughtsmanship and the good drawing of the figure and decorative sculpture. The entrance hall and staircase are placed in the eastern part, and serve for both concert-hall and theatre, a mistake we have already pointed out in the prize design in the event of there being entertainments in both at the same time. The elevations show a want of study of scale. Thus the ground-story arcade seems to be drawn to a scale of 16ft. to the inch, the first floor to a scale of 8ft. to the inch, the

upper story of towers on the extreme right and left to a scale of 6ft. to the inch, the centre portion on the same floor being of the small scale again. The whole design is suggestive of being the work of a student who has hitherto strictly designed in the Gothic style, and who adopts Classic as being more in harmony with the subject. It is but fair to state that he shows considerable ability in his new style, and the sculpture and ornament and the decoration of the sections are well designed and admirably drawn.

The £25 premium awarded to students of the upper school, for the best design executed within the walls of the Academy, was carried off by Mr. W. R. Lethaby (the Soane Medalist, R.I.B.A., of two years ago), for a design for a "Bishop's Tomb." There were four competitors only, as the particulars of the prize were not announced till May, in consequence of the alteration of the Academy rules. This, and the £10 premium, awarded to students of the lower school for a similar subject, are new prizes, and will, doubtless, in future, excite the keenest contest, because they are rewards for work done in the ordinary curriculum of the school, and place architectural students on the same footing as painters and sculptors. Mr. C. B. Leach carried off the £10 prize with a design also for a "Bishop's Tomb." The subjects are given by the visitors, and are the same for both the upper and lower school of students.

The subject given for the Measured Drawing Models was Stone Church, Kent, a plan, three sections, and one sheet of details being asked for. Mr. W. Bassett Smith carried off the 1st medal, and Mr. Thomas Yates the 2nd. There was no competition for the Perspective Model this year in either school.

For the Gold Medal and Travelling Studentship of £200, offered for the best historical painting, the subject being "The Messengers Coming to Job," Cf. Job I., Mr. S. M. Fisher carried off the prize with a painting above the average, well conceived, and powerfully painted. Mr. Fisher has caught the spirit of Eastern life in the dark, sombre room, lit up only by the light admitted through the doorway, the curtain being partially raised by the messengers coming to announce great tidings of disaster. Job himself, on the right, is sitting on a couch, with his face filled with dismay and agony, as much for his servants' misfortunes as for his own sad fate; his wife stands behind partially supporting him, with her face turning round towards the door, in apparent bewilderment at the series of troubles suddenly come upon them; whilst at Job's feet in the foreground is one of the servants, half-dead with fear. The accessories are all carefully studied, and the painting well merits the encomiums passed on it by the President. The painting with the number 4 on it has a well-conceived figure of Job standing in front of his tent, but the other figures are poor, and have no action or meaning. For the Turner Gold Medal there were two or three formidable rivals to Mr. Hook, but there is more sentiment and power in his work. The distribution of the medals and prizes was followed by the address of the President, Sir Frederick Leighton.

PROF. RICHMOND ON SCIENCE AND ART.

THE eighteenth annual distribution of prizes to the pupils at the Devises Government School of Science and Art took place on Tuesday week. Prof. W. B. Richmond delivered an address, in the course of which he said:—An accumulation of interest (if I may use that term) has gone on year by year in England, on this subject of art; but, let us all remember that mere education is not all that is wanting. It is

not the mere fact of learning to draw correctly and accurately that will ever make an artist, any more than it is the fact that a musician will be enabled to invent music by learning the notes of the piano. The whole mind must be elevated and stimulated by a desire for that which is noblest and most beautiful before that mind can appreciate it. (Cheers.) The facilities of modern education are in all respects great, both for good and for evil. Literature abounds in both; but the duty of every young artist, or of anyone studying art, is first to abhor and abjure all literature which tends to degrade or disgrace his mind, and adhere strictly and firmly only to that which will elevate it and bring it into the realms of poetic and noble thought. Further than this, there is an education of the eye which may take place in most of our daily surroundings, and this we must not neglect. And then the subject of taste. If I make use of the word taste, you will ask me what I mean by it? You may say there is no standard of taste; taste is an individual peculiarity. No; taste may be summed up simply in one word, congruity: anything is in perfectly good taste which is perfectly fitted for its purpose. If we take furniture, for example: a most abominable fashion prevailed not many years ago wherein our chairs and tables were made with inconvenient knobs, so that where we sat we were pricked, and where we would rest we were abominably annoyed. Now, we have all heard of a school called the *Esthetic School*; that school has desired that things should be fitted for their purposes; that chairs should be sitable upon, and that sofas should have a degree of comfort; that you should not find in the centre of the table a knob, and that your dinner should not be destroyed by agonies of pain. On the other hand, on the practical side, you will see that the simple forms to which furniture has been reduced are most admirable and suitable patterns for the objects of every-day use. There are many here probably who propose to make themselves into artists some day hence. You all know of the cultivation of the eye and the cultivation of the hand; that both must be very much practised. But the mind and sympathies must be cultivated also. Now I would advise any young man here, who proposes to succeed in his profession, never on any plea whatever to be without a pencil and a book. In the great days of art in Italy, when art was at its prime, when it was the handmaid of religion, when, I may say, it was the conductor of morals, the great men of Italy, those who rose to the highest fame, passed their days and their nights in constant study and work. One of the greatest of these, and that because he was as much a scientific man as an artist, was Leonardo da Vinci; so much did he love art that he followed criminals in their confinement in order to watch the varying workings of conscience upon their features. He used to invite peasants and make them laugh by relating extraordinary stories, and so catch the expressions of their faces, and afterwards draw them from memory. You will see that it was necessary for him, in order to portray these varying emotions, vastly to exercise his memory, and I recommend to all of you to adopt the same plan: never omit making a note of any impressive scene in your notebook on any chance whatever; if you see a face which strikes you, draw it; if you see a piece of scenery which impresses you, make a note of it; omit nothing; keep your pencil in your hand, and you will become an artist (cheers). Leonardo da Vinci was the painter who painted the "Last Supper," who painted some of the finest portraits in the world, who foresaw much modern science, who was the precursor of Newton and Galileo in scientific works. Science and art in all the greatest ages of the world have gone together. There is no more absurd sentimental nonsense than the creed, extremely fashionable some twenty or thirty years ago, which held that science and art must be for ever severed. We have had no great art without the assistance of science. With art alone, however true it may have been, until it has had science come to its aid, it has not arrived at its fullness and ripeness. In the earlier part of my remarks I ventured to tell you that education is not everything. There must be inherent in the mind of him who would be an artist a strong desire to express something through the language of art that he cannot express in the language of litera-

ture or music. Nearly 700 years ago, in Tuscany, in a quaint little town I visited myself, a little shepherd boy, the son of a poor peasant, kept his sheep. These sheep, his only charge, and the charge that he loved best, the charge nearest to his heart, he drew upon a flat crag of rock with a little bit of burnt stick which he got from his father's hearth. There the boy dreamt in his imagination and endeavoured to learn; this in a sense was his academy. The boy that I speak of was Giotto de Bondoni. Italy had just at that moment got from Greece, or rather from Constantinople, many great painters who had come in order to adorn St. Mark's at Venice. That being finished, the great artists sprang themselves over Italy and instructed the Tuscan painters. One of these, Cimabue, had already made a great name in art, and passing through the country where young Giotto lived, Cimabue saw the boy making what we must suppose to have been accurate drawings of his sheep, and saw, through all the foibles of the boy's art, that there was an instinctive love of what he was doing. Hand in hand they went to the father's hovel, and the great painter, then almost a prince in Italy, asked permission to take the little shepherd boy and make a painter of him. From the humblest little boy that you can imagine, this Giotto became the friend of the great genius of Italy, the poet Dante. This he became, not from any definite education, but from his love of art, his will and perseverance, and his determination to tread down whatever barrier might be between him and his love. In his youth he drew those humble sheep; afterwards, as he became a man, he travelled from city to city adorning their churches. Thus he became a prince in art, and remained a princely humble soul until the day he died. Now, this is an instance of what perseverance and a true instinct will do to help a man on. We may come down to far later times, and find exactly the same thing. Turner, our great English painter, was a barber's son, lived on the banks of the Thames, and spent the early part of his days amongst shipping; yet that man, despite all the disadvantages of his early training (for he never really learnt the English language properly), became one of the greatest painters that the world has ever seen. I will give you another instance of what a man may do. Scarcely ten years ago died one of the greatest, perhaps the greatest, of all the French painters, Jean Francois Millet. He was a peasant's son, and was educated entirely by his grandmother, who was a pious worthy woman, and who educated him entirely upon the Psalms of David and the ancient books of the Bible. The fervent love that this man had in his heart and the love of labour which inspired his healthy soul by his observation of the workpeople constantly around him, made him what he became—eminently the painter of peasants. No one has ever painted the real peasant in the perfect similitude of toil and its dignity as he has done. In none of his work is there the smallest essence of caricature. It is throughout exquisitely noble, and in every touch it proclaims the dignity of toil. Throughout his life of hardship—such as I hope no one in this room has ever known or will know—so near starvation that his proud soul had once to demand bread of a friend to support his seven children,—this great man still worked on through it all, still living in the little village in which he was born, and having no desire to go to the great city, whither had he chosen to go and to give way to the French taste, he might have made his thousands a year. Happily in the latter years of his life some consolation came and he got a name for his pictures. I will just give you one anecdote with regard to Millet which will prove the power of regarding things not from an educational point of view. Wandering in the fields one evening he saw two peasants; a woman put down her wheelbarrow and a man took off his hat and put down his hoe, whilst over the flat plains of Normandy came the sound of the evening bells. This scene he determined to paint. He did it in silence, alone, and from memory of the impression that had been conveyed to him. A friend came one day and said, "Turn that picture and let me see what you have done." He did so. "What is your impression?" said Millet. "My impression is that you have painted sound." This shows how, if a man has a firm determination to do a thing, he can do it. This is how Millet

did it. On certain evenings only could he hear the sound of the bells coming from the village. He said, "Only on those evenings could I paint." I could not realise my dream unless the atmosphere were perfectly consonant with my idea, and I could feel the sound travelling over the plain." I must not, however, detain you longer with anecdote, but say something about the largeness of the boundaries of art. It has been a common modern fallacy to suppose that because a man can do one thing, therefore he can do nothing else. It does not at all follow that because a man is an admirable painter that he shall not be able to make and model a mass of iron to serve a beautiful purpose as a gate. All this displacement of art has tended to its decay. The blacksmith, or the carver of capitals for churches, may be as great an artist, if he chooses, as the most dignified painter who ever adorned the walls of a church, but his being an artist depends upon two things—his absolute sincerity of workmanship and his absolute sincerity of design. There must be no work scamped; no design made without a reason for its fulfilment. Albert Dürer, while he was designing the most beautiful imagery of the life and death of our Saviour, was at the same time making designs in other branches of art. Holbein, when he was employed by Henry VIII. in painting the portraits of his wives, was likewise employed in designing of a different nature. Do not think, because any of you may be following what is considered a lower branch of art, that, therefore, you are not holding the dignity of artists. What your dignity as an artist depends upon is simply this. That you do your work as well as you possibly can, and that you have a reason for all that you do. Now probably many, if not all of you, have been to Venice. As you approach that wonderful Basilica, you are simply struck with amazement at the gold and blue and purple and the fairy-like appearance of the whole. If you approach it as I have done, with a scaffolding put up to enable you to examine it in detail, you find there is not a foot of workmanship that is not painted, not only with the minutest care and the greatest love, but with deep and infinite invention of the workmen. Remember, in the days of Italy it was not as it is now; architects did not in those days give full and entire drawings for every detail of their work; that was left to the workman, who being an honest man did his best, and this is the kind of art that we want to get back into this country. What we want to get back into England is that individual axiom of each human being's mind—leaving a trace upon the building that he touches. And this is only done by an infinite love of his art, and that is only got by industry. We all know that in the progress of work, if we can only pass over those first few moments, or hours sometimes, of idleness, how there is an accretion of pleasure, how the grappling with one difficulty after another makes the fight a perfect idol to our souls, and how after difficult struggling we get a most infinite satisfaction. It is so in the whole conduct of our lives: there is no pleasure got out of anything except by struggling. He who puts down his pencil at the first effort can neither be considered to be a good man nor an artist; he who succeeds is the man who through all difficulties breaks down, with the weight of his perseverance, every strong barrier that evil or good fortune may set up before him, and he is the man who will and may become as great as any of the old artists of Italy. Now, gentlemen, in conclusion I must give you a few words as regards the study of art. With reference to the works that I see here I am bound to say that on all occasions I like to be honest, and although I differ somewhat from the manner in which some of the works are executed, I do see considerable strength and vigour in nearly everything here. I am very glad indeed to be able to congratulate those ladies and gentlemen on the drawings from life; because very much as we must all appreciate the value of drawing from a still object, still (I did not mean to make a pun, it is always a dead thing; there is a want of life in it. You may have the most beautiful casts in the world, but there is not the same vital interest in copying from them as from the human face, and I would advise all those who are going to devote themselves even to the study of art as a pastime, to draw as much as possible from nature. At the same time I quite agree with what has been said, that you ought to have some room where you can have casts and objects

of study; but I am bound to say, rather than draw from these I would advise an analysis of them—a minute analysis—in conjunction with the study of the human form. I have passed through a great deal of that kind of work in my life. I have seen others go through it. I have known many and many a man who was able to make an admirable drawing from an antique statue, but as soon as he attempted to draw from the life he was entirely at sea. All the strength of expression is in movement, and if you cannot express that, you really have learnt very little indeed. You may have learnt to put a nose into a face or an eye into its proper place, but not to convey to these any human expression. I would advise with all my heart that you draw from Nature on every possible occasion; draw your friends under any influences; draw them when they are not looking, and draw them with some definite expression. Use your memory, above all, to do that: do not think that it is necessary always to have a thing stuck up in front of you; but try to get the impression of it in your mind, and you will find as time goes on that your memory will have acquired such precision that you will be able to compare that which you have been doing from memory, and without the copy before you. I would also recommend that you should model. It is a most simple operation. You should use wax, and if you will attend to what I say for two minutes you will be able to follow it. If you want to make a model in wax, buy a pound of beeswax, add oil, and put it into a hot caldron. If you wish to colour it, add vermilion. Mix this up together, and you have a material with which you may model almost anything. This plan was used by the early Italian sculptors for either small or middle-sized works. My reason for advising you to use wax is on account more especially of those students who have not very much time to spare at once. Wax is not fragile, and does not require any wetting like clay, but it may be easily softened at any time by the mere warmth of the hand, so that a person may do a little bit at a time, at his leisure. One word more and I have done, and that is, ladies and gentlemen, I must very much congratulate you upon your master. It has been at once my pleasure and my duty to deliver a great many addresses to different Schools of Art in England and Scotland, to see a great many productions, but I am bound to say that I have seen none that excel in careful workmanship that exhibition which I have now behind me. There is apparent a remarkable neatness in the work, and I think a great deal of neatness, because neatness and preciseness have much to do with the charms of art. Now this neatness could not have been got unless you had the advantage of studying under a trained and capable master. In conclusion, I wish you every success, and I hope that those of you who intend to become painters may remember on your deathbeds the happy days you have spent at the Devizes School of Science and Art.

SIR F. LEIGHTON ON ART.*

WHEN at our last biennial gathering I addressed you from this place it was my endeavour to indicate to you, with what consciousness so wide a subject permitted, a solution to certain doubts and perplexities concerning the position of art in the modern world which, as I said, are apt in these days to assail the minds of students who think as well as work. I sought to show you, in answer to these doubts, that we have no cause for misgiving in regard to the continued vitality of the arts we follow, inasmuch as they have their root in deep needs and undying instincts in our common nature; and I exhorted you to work on in unwavering faith that the day is not at hand when the expression of æsthetic emotion through the forms of art shall fail for lack of answering echo in the hearts of men. There is, however, a grave question connected with the imitative arts of painting and sculpture to which on that occasion I only passingly alluded and to which I purpose to devote a few words this evening; a question on which widely divergent opinions stand opposed one to the other and are upheld with equal tenacity—namely, the question "What is the relation in which Art stands to Morals and to

Religion?" The solution of this question has a twofold bearing on the young artist who is about to submit his work to the ordeal of publicity—a direct and an indirect bearing. On the one hand, the answer to it which he frames for himself will determine the direction into which he will incline to bend his energies; but he will, on the other, be hardly less powerfully affected by the view which prevails in regard to it in the general mind—that is to say, in the intellectual atmosphere which he breathes and by which he is, though he be unconscious of it, largely moulded; for on the conception entertained of the aims and ends of art must depend the mode in which its achievements are judged, and it is evident that a mistaken view of those aims and ends must taint the appreciation of the qualities exhibited in the production of a work of art, and tend to the subversion of all sound criticism as well as to the bewilderment of those young artists whose native instincts are not sufficiently imperative to carry them unwaveringly along their path. And the problem of the relation of art to ethics is one which assumes in this country exceptional prominence from the mental and moral peculiarities of our race. There is, I suppose, no country in the world, unless it be the sister-land beyond the Atlantic, in which the religious sense has exercised an influence so definite and so controlling as it has in our own on the development of the intellectual as well as of the ethical tone of the nation. In the moral order this sense has added incalculably to the strength and dignity of the national character; in the intellectual order its overmastering influence has too often tended to cramp and impede that full and equal play of the intelligence without which our nature cannot yield its fullest harvest or bear its finest fruit. There is, therefore, no country in which the task of unraveling the complex question of the true relation of morality and religion to art is one of greater delicacy. Now, what are the doctrines between which the perplexed student finds himself tossed hither and thither on a sea of controversy? On the one side it is asserted that the first duty of all artistic production is the inculcation of a moral lesson, if not, indeed, of a Christian truth, and that the worth and dignity of a work of art are to be gauged by the degree in which it performs this duty; unless it preach, as from pulpit, the cardinal doctrines of the Faith, or declare—whether by unambiguous symbolism, or by definite embodied example—the loftiness of virtue and the deadliness of sin—unless a very gospel made more eloquent by form and colour cry aloud to us from the canvas or from the marble—then, we are told, the artist has laboured in vain, for his work fails in the fulfilment of the highest function of art. With this contention connects itself naturally, if not necessarily, this other—that as a man is mirrored in his work, so the noblest work can be and has in fact been produced only by the most pious and God-fearing men, of the moral level of whose nature it is indeed the test and, as it were, the tidemark. These views, of which, whatever their intrinsic and final value, the moral elevation is very attractive to certain natures, and which have been supported, if not substantiated, by impressive illustrations, have found many advocates, and have been proclaimed with the passionate eloquence of an overmastering conviction. And they have been pushed to strange lengths; some men, carried away by an unrelenting logic working on an ascetic temperament, have been impelled to assert that the application of art to any save a definite religious end is little less than an act of moral depravity; and a great and nobly gifted artist, Friedrich von Overbeck, has not hesitated to declare his opinion that when Raphael painted his famous Galatea in the Farnesian the Lord had abandoned him. A further, and the strangest development of this frame of mind, one with which I have myself, in my youth, come in contact in Germany, is that which sees in the excessive love of colour an almost culpable indulgence of the senses. Such views, indeed, are not likely to find favour or acceptance in the country of Gainsborough and Sir Joshua Reynolds; they are, nevertheless, interesting as showing to what extremes the doctrine of the dependence of art on religion may and sometimes does lead its followers. In opposition to this doctrine it is maintained, on the other hand, that the function of art, as such, whatever may be its incidental operation and whatever it may include in the broad verge of

* Address of the President of the R.A. to the Students, delivered Dec. 10th.

its sphere of action and appeal, is absolutely unconnected with ethics, and that its distinct and special province is to satisfy certain cravings and excite certain emotions in our nature to which it has alone access; and that without art not a few of our keenest and deepest capabilities of emotion would lie unaroused and barren within us. The corollary generally attached to this proposition is this—that, as artistic production springs from æsthetic and not from ethic impulses within the artist, so the character of that production is independent of his moral attitude and unaffected by it. These two theories, which stand arrayed one against the other, are in appearance so consistent in themselves, their respective propositions seem to flow so naturally one from the other, that the student who sees them distinctly formulated is tempted to fling himself without further question into the arms of one or of the other, accepting it unreservedly and in all its parts. My task to-night is to give you reason, so far as the limits of our time may allow it, to doubt the wisdom of such a course, and to ask you rather to believe that, while art is indeed in its own nature wholly in dependent of morality, and while the loftiest moral purport can add no jet or tittle to the merits of the work of art, as such, there is nevertheless no error deeper or more deadly—and I use the words in no rhetorical sense, but in their plain and sober meaning—than to deny that the moral complexion, the *ethos*, of the artist does in truth tinge every work of his hand, and fashion, in silence but with the certainty of fate, the course and current of his whole career. Let us look more closely into these assertions. The theory which, for convenience, we may call the didactic theory is founded on *à priori* reasoning and is supported by reference to facts. It is in effect postulated, somewhat arbitrarily, by its advocates, that every higher expression of our emotional nature must, in order to merit the favour of mankind, aim directly at moral edification, and that this moral edification is to be achieved only by the inculcation of moral lessons; and it is further asserted by them that this has been, in fact, the character and tendency of all the greatest art the world has seen. There can be no doubt that the evidence which is marshalled in support of this view seems at first sight formidable and even overwhelming. Modern painting—using the word modern in the wider sense and to distinguish it from that of the ancient world—was reared, we are bid remember, on the lap of Christianity, and received its loftiest themes from the Church of it was, as we are constantly reminded, the faithful handmaid; and, accordingly, from the hour of its dawn to the high noon of its strength a continuous host of divinely endowed artists is shown to us, testifying in unnumbered masterpieces to the glory of the Almighty and of his Saints. We see them handing down undimmed, from generation to generation, the lamp of their steadfast faith, and from the harmonious concert of their works, as from a vast consenting choir, does not a solemn anthem seem to roll across the centuries, crying from a thousand throats, “Hosannah! Hosannah in the Highest”? With the decline of faith, on the other hand, we are taught to connect that downward course of art, which begins to manifest itself towards the close of the 16th century; and in the absence of any religious afflatus in the great Dutch and Flemish masters of the 17th century, we are invited to see cause—even though one of them be called Rembrandt and another Rubens—for placing them in a rank lower than the foremost. Nay, more, turning to the ancient world, the greater loftiness of Greek sculpture in the Periclean than in the succeeding ages is attributed to the primitive piety which prevailed up to that period, which breathes throughout the pages of the great historian of Halicarnassus, and burns on the lips of the Titan Æschylus. Time would fail me to-night to test minutely the value of the evidence which I have here summarily indicated. I will limit myself to the consideration of two or three points which suggest themselves on a closer examination of this array of facts, or, rather, of assertions. It can be argued, in the first place, that they do not comprise the whole body of evidence to which we must look if we would form an impartial conception, and take a comprehensive view of the question; secondly, that the evidence adduced is not, even where it seems strongest, so accurately corroborative of the theory as is contended, and as may, at the

first glance, seem; and thirdly, that through the whole contention lurks the fallacy of mistaking a co-efficent for a—nay for the—primary cause. As a striking instance of evidence that must be either omitted by the upholders of the didactic theory or admitted by them to be hostile to their contention, Spanish art will at once suggest itself to you. There is, probably, in the history of the world, no such illustration as that afforded to us by Catholic Spain of the absolute, irresistible, all-embracing supremacy of religious faith as a controlling influence in a national life, whether public or private; and assuredly the lurid fervour of that faith had not waned in the days of Spanish greatness in the field of art. That the Church should exert her influence in that field also, and more dictatorially even than elsewhere, was a matter of course, and accordingly we find in the Iberian Peninsula a school of religious painters of an ascetic type, men of stern piety, and noteworthy if not great—a Morales, for instance, who earned for himself the surname “El Divino,” a Juanes, a Luis de Vargas, who wrought in the intervals of fasting, of prayer, and of self-flagellation, and lived in the constant contemplation of death and of the grave. Yet who will seriously claim for these men the same level of artistic excellence with that which is held by the great painters of the 17th century—by a Murillo, whose religious works have, with few exceptions, so little of real religious inspiration, or a Velasquez, the most mundane of painters and Shakespearean almost in the width of his mental objectivity! Again, we need not linger on the sweeping disparagement of the later Dutch and Flemish masters which is logically involved in the didactic theory and which carries with it the exclusion from the highest places of that supreme painter who revealed to the world the poetry of twilight and all the magic mystery of gloom, Rembrandt of the Rhine. Let us consider, rather, for a few moments, the more specious argument drawn from the growth of painting in Italy; and let us first once aim call to mind the position assumed in the didactic theory; it is that, the moral edification of men being the highest duty of art, those productions of art will take the highest rank which teach, with sincerity and of a definite purpose, the greatest number of moral truths, and that the painter who, the artistic gift being, of course, postulated, aims most constantly at the inculcation of these truths will produce the greatest works. You will at once feel that these assumptions, if accepted without reservation, sap at the roots of all free criticism, practically substituting for it a foregone conclusion. A critic who approaches a work of art under their influence will instinctively gauge it in accordance with them, however inclined he may be in the abstract to weigh it with a more scientific impartiality. We must be careful, therefore, in testing this doctrine by the light of facts, to bear in mind, in weighing these facts, the general verdict of enlightened opinion ripened and confirmed by time. Now if, on a review of Italian art from its rise to its zenith, we ask ourselves which works have by the consent of the vast majority of the intelligent been pronounced the most mature and perfect, we shall not find that verdict harmonising with one which should be built up on the axioms of the didactic theory; we shall, on the contrary, find that the evolution of art in Italy, an evolution singularly organic and continuous, bears no ratio, unless it be an inverse ratio, to the religious life and development in the midst of which it ran its course. It is a matter of notoriety that with the more general spread of classic literature throughout Italy in the 15th century, partly through the Italian Humanists, and partly by the agency of Greek refugees fleeing westward before the conquering hordes of Mahomet II., a disintegrating effect was pronounced on the religious beliefs of that country. For more than a century already a seething restlessness had obtained possession of the minds of men; nature was fast rising within them in rebellion against the ascetic teaching of the Church; and when to minds so prepared the revelation was suddenly offered of a literature fearless in speculation and broadly based on the equal development of all the human faculties, a literature, furthermore, of which the Latin branch breathed, in every line, of that distant national greatness to a sense of which in the previous century the friend of Petrarch, Cola di Rienzi, had sought not vainly to kindle and inflame his

countrymen, a revulsion long prepared was operated among the Italian people, and from one end of the land to the other a thrill, as of a newly-awakened life, ran through them, stirring within them as the sap stirs within the wintry trees under the first mild sweet breath of Spring. But not ancient literature alone roused them to a new consciousness and a fieri-er emulation; fragments of antique statuary few, as yet, but sufficient, were exhumed under their wondering eyes, and behold, the frame of man, that tenement of clay which they had been taught till now to regard as a thing to be mortified and held in contempt, suddenly arose before them in a new-born dignity, transformed by an ideal, their shame no longer, but their pride. So, under the influence of this awakening, this Renaissance, as we call it, art, like letters, put on a new physiognomy; with the vindication of human nature and the newly-accepted view of life as a thing wherein to rejoice, the forms in which life reveals itself became a source of absorbing interest and a worthy subject of study for their beauty's sake. The young scientific spirit which at the same time flamed up in a very passion of enthusiasm came powerfully to the aid of the artist. The study of anatomy emerged from its hiding-places, and was practised in the open day; perspective was eagerly studied, and exercised on the minds of artists a fascination which, in our day, seems strange enough, obtruding its problems every now and then in their works in the most unexpected and naively far-fetched ways. A more healthful east of beauty was by degrees developed, and we thus see art gradually expanding and rising to a fuller dignity and a loftier level through causes wholly foreign to and not coincident with religious growth. In fact, with the rising tide of the humanistic and scientific spirit, the religious spirit was not gaining in strength and fervour. On the contrary, the powerful revulsion of feeling of which we have just noted the effects in the world of the intellect and of the imagination operated also, as might have been expected, on the beliefs of the cultivated masses, and loosened the hold on them of that religious teaching which men could not dissociate in their minds from the intellectual thralldom in which the Church had hitherto sought to hold them. The cause of morality undoubtedly suffered with that of doctrinal religion, and those who value most highly the priceless boon conferred on the world by Italy in the 15th century cannot but recognise with sorrow that it came alloyed with much dross and touched with much taint of corruption. So low was the moral tone of large number of the humanists that we recall with a sense of relief as well as of gratitude the names of such men, for instance, as Vittorino da Feltre, Guarino, the countryman of Catullus, Giannozzo Manetti, Pomponio Leto, or Pico della Mirandola, in whom wisdom and learning went hand in hand with every Christian virtue. And if it be not true that Italian art owed its highest unfolding to the impulse of religion and the purifying atmosphere of faith, neither is it true that its decadence was the result of the waning of faith and religion to which I have just alluded. Nor was it coincident with it in point of time. Nay, that malarious moral taint which hung about the footsteps of the Renaissance in the day of its complete ascendancy, and polluted so much of its literature, is not traceable, and then in a far less degree, till a century later in the plastic arts; so purifying, I had almost said so anti-septic, are those arts in their very nature and in their influences. Indeed, the causes of the downward tendency of art towards the close of the 16th century must be sought less in the failing of the religious faith among artists than in the excessive and too exclusive faith in mere science. Artists had now drunk deeply of the springs of knowledge, and were intoxicated in the strength of this rich new vintage; they had investigated the wondrous mechanism of the human frame with a scientific thoroughness never till then brought to bear upon it; they had explored the science of composition and measured the expressional resources of abstract form; but they too often forgot that the province of art is to speak to the emotional sense, not to make vain exhibition of acquired knowledge, and that work which reveals in the workman no impulse warmer or higher than vanity or a thirst for display will for ever fail to move

the hearts of men. Accordingly, we see the gradual supersession of sentiment by scientific pedantry marks faithfully the decline in sterling artistic nobility. Correggio, who, indeed, still rides on the crest of this great wave of art, combines, no doubt, a true artistic passion with the most consummate knowledge, but we seem conscious in him already of the last moment of perilous poise; in the Caracci and their school pedantry too often triumphs; in Tiepolo, the last of the Venetians, the acrobat lurks everywhere in the man of genius. I have in the foregoing remarks on Italian art turned my attention to painting exclusively. I have done so because just as sculpture is, in an emphatic manner, the characteristic expression of the Greeks, so painting was pre-eminently the art of the Italians, and because, further, the upholders of the didactic theory lean habitually more on the painting of Italy than on her sculpture. Nevertheless, the growth of that art on Italian soil, fed as it was from the same sources, fostered by the same influences, and breathing the same intellectual and moral air, followed the same course as painting, and though it culminated in the hands of a man as sternly religious as his great spiritual predecessor, Dante, in the main the plastic art rose on the same pinions, flew with the same flight, and fell at last stifled in the same lethal fumes as did her sister, Painting. One word concerning Greece before leaving this part of our subject, since Greece, too, is, as I said, not infrequently quoted in support of the views I am combating to-night. We are tempted, when the bearing of religion on Greek art is pressed upon us, to ask which religion is here alluded to; for in Greece, as elsewhere in the heathen world, there was a religion of the few, the purer and the more abstract, and the religion of the many, the more tangible and the less pure; the faith in one Supreme God, great among all gods, free from sin, and wholly unlike men, or the faith in that joyous fellowship of gods and goddesses, loving and hating, scheming and boasting, founders of dynasties on the earth, whom the Greek race, if it borrowed the first conception of them from far-off ancestors in a dimly-remembered East, had finally moulded, as was their nature, after their own living likeness and image. Of the former, however strong the impress with which it has stamped the poetry of Greece, it would be difficult to show its direct influence on the plastic arts. It seems to me to be far-fetched in the extreme to trace any definite ethical purpose or high religious character, even in those sculptures, the noblest of all known to us and unapproached as yet in their lonely greatness, which have come down to us under the name of Phidias. Of the popular religion of Greece, it would, perhaps, be safer to say that it owed much to art, than that art was strongly influenced by it. The gods, as they were conceived by the masses, were in the main the embodiment of that exuberant sense of life and that over-mastering love of beauty which was the distinctive privilege of their race no less than the life-breath of their hearts. In sum, then, we may, I think, say that, as far as we have seen, a cursory glance at a few of the points adduced in evidence for the didactic theory does not seem to justify the use made of them, and rather shows us art, not, in truth, undisturbed by the moral characteristic of those who practice it, but withal growing its own growth as a distinct organism with its own principles of life and fed by conditions in which intellectual, moral, and physical causes each play their appointed part. But if the illustrations by which it is sought to buttress this theory do not in fact uphold it, let us see how it stands with the doctrine itself viewed on its own intrinsic merits. Now, the reasoning on which the didactic theory is built up would seem to be this—the moral sense is the highest attribute and the distinctive appanage of man; its strengthening must, therefore, be man's noblest duty; and the dignity of all human intellectual achievements must be according to the degree in which this end is primarily and professedly subserved by it. But here a difficulty at once presents, for the consistent application of these views involves, among other consequences, one in all ways new, I venture to think, see the end of the whole theory: it involves the debarment of an art closely akin in its ways to those we follow, like them a labour common to all races, like them from time immemorial a channel of purest emotion,

an art divine, if a divine art there be—the art of music. The dignity of music has, indeed, strange though it may seem, not remained unchallenged. Such heresies may, however, safely be left to their own foolishness. It is given to the supreme few who occupy the solitary mountain tops of fame to be able to express, without incurring the charge of vanity, their high consciousness of the value to the world of the gifts they bestow upon it. One of these few was Beethoven, and his proud words are there to show us in what esteem he, at least, held the power of the art on which he has risen to immortality:—"He to whom my music reveals its whole significance is lifted up"—these are his words—"is lifted up above all the sorrow of the world." And assuredly the art which has borne up and daily bears up in oblivious ecstasy so many weary souls, which has lulled and cheered, if only for a moment, so many aching hearts, and which in its endless plasticity has a response for every mood of the imagination and a voice for every phase of feeling, is rooted too deeply in the general love and reverence to fear the onslaughts of any logic-ridden crotchetermonger. Yet, let me ask, what definite moral truth is taught by it, with all its universality? What ethical proposition can it convey? What teaching or exhortation is in its voice? None; absolutely none. Meanwhile we may safely affirm that a doctrine which should lead in its logical application to the exclusion of this art from the first rank among the intellectual agents which raise mankind is tainted with grave fallacies. What, then, are these fallacies? They are, I think, the following:—First, the assumption that the pursuit of moral edification can alone confer a claim to the respect of men; secondly, the assumption that moral edification can attach only to direct moral teaching; and, thirdly, the assumption that any mode of expression by which appeal is made to the emotional faculty and the imagination can be exercising its highest office except in the application and development of its own distinctive resources, and in seeking to convey those emotions of which it is the proper and especial vehicle. And this last fallacy lies at the root of the matter. Now, the language of art is not the appointed vehicle of ethical truths; of these, as of all knowledge as distinct from emotion, though not necessarily separated from it, the obvious and only fitted vehicle is speech, written or spoken—words, the symbols of ideas. The simplest-spoken homily, if sincere in spirit and lofty in tone, will have more direct didactic efficacy than all the works of all the most pious painters and sculptors from Giotto to Michael Angelo, more than the Passion Music of Bach, more than a requiem by Cherubini, more than an oratorio of Handel. It is not, then, it cannot be, the foremost duty of art to seek to embody that which it cannot adequately present, and to enter into a competition in which it is doomed to inevitable defeat. On the other hand, there is a field in which art has no rival. We have within us the faculty for a range of emotions of vast compass, of exquisite subtlety, and of irresistible force, to which art, and art alone, among human forms of expression has a key. These, then, and no others, are the chords which it is her appointed duty to strike; and form, colour, and the contrasts of light and shade are the agents through which it is given to her to set them in motion. Her duty is, therefore, to awaken those sensations, directly emotional and indirectly intellectual, which can be communicated only through the sense of sight, to the delight of which she has primarily to minister. And the dignity of these sensations lies in this, that they are inseparably connected by association of idea with a range of perceptions and feelings of infinite variety and scope. They come fraught with dim, complex memories of all the ever-shifting spectacle of inanimate creation and of the more deeply stirring phenomena of life, of the storm and the lull, the splendour and the darkness of the outer world, of the changeful and transitory lives of men. Nay, so closely overlaid is the simple æsthetic sensation with elements of ethical or intellectual emotion by these constant and manifold accretions of associated ideas, that it is difficult to conceive of it independently of this precious overgrowth. I cannot here enter at any length on this most interesting subject, but a moment's reflection will furnish you with illustrations of it. You will find, for instance, that, through this operation of association, lines and forms and combinations of lines and forms, colours and

combinations of colours, have acquired a distinct expressional significance, and, so to speak, an *ethos* of their own, and will convey, in the one province, notions of strength, of repose, of solidity, of flowing motion, and of life; in the other, sensations of joy or of sadness, of heat or of cold, of languor or of health. It is this intensification of the simple æsthetic sensation through ethical and intellectual suggestiveness that gives to the arts of architecture, sculpture, and painting so powerful, so deep, and so mysterious a hold on the imagination. And, here, also we find the answer to the second of those fallacies to which I just now alluded—to wit, that moral edification can attach only to direct moral teaching. The most sensitively religious mind may indeed rest satisfied in the consciousness that it is not on the wings of abstract thought alone that we rise to the highest moods of contemplation or to the most chastened moral temper, and assuredly arts which have for their chief task to reveal the inmost springs of beauty in the created world, to unfold all the pomp of the teeming earth, and all the pageant of those heavens of which we are told that they declare the glory of God, are not the least eloquent witnesses to the might and to the majesty of the mysterious and eternal Fountain of all good things. We should thus find ourselves abundantly armed, were it needful to be so armed, to meet those who affirm that to convey moral edification can alone give the highest status to an intellectual pursuit. But we have no need of defence against a fallacy so palpable, a fallacy of which the adoption contains the disparagement of every form of pure science with all its marvellous achievements—achievements more marvellous than the dreams of fancy, and in their results unspeakably beneficent. On the absurdity of such an attitude it is needless to dwell. In fact, the nature of man is a complex organism in which are many and various germs of growth, and only in the full and balanced development of these several elements can that organism achieve in this world its perfect maturity. To art belongs the development of one group of these rich and fruitful germs—a sufficient, and, surely, no ignoble task. Much would, indeed, remain to be said in further elucidation of this part of our subject, but the limits of my time warn me to draw to a close. It remains to me to say, in conclusion, a few words on the bearing of the ethical tone of the artist on his work and on his career. At the beginning of this address I drew your attention to the fact that of those who claim for art a separate and independent sphere—a claim which we have just seen to be well founded and unassailable—many tend further to assert that, therefore, artistic production receives no colour from the moral temper of the producer. This I called a dangerous error, and affirmed, on the contrary, that the man is stamped on his work, and his moral growth or lessening faithfully reflected in the sum of his labours. I believe this to be a cardinal truth, the disregard of which may bear fatal fruits in an artist's life, and I have no warmer wish than to stir in you and leave with you, if it may be, to-night some sense of the grave importance of its bearing upon each and all of us. The more closely you consider this subject, the more clearly will you feel, for instance, the mischief to us as artists which must infallibly attend a tolerant indulgence within ourselves of certain moral weaknesses and failings to which nature is too often prone. Of these failings some are palpably ignoble, and, in the long run, debasing; others are not on the surface so evidently mischievous. Among such as are palpably ignoble I will instance the greed for gain. I believe no evil to be more insidious, none more unerring in its operation than this sordid appetite. Its poisonous taint creeps into the moral system; numbs by degrees all finer sense; dulls all high vision; is fatal to all lofty effort. No worse snare lies across our path. Another such deadening taint is the vulgar thirst for noisy success, the haughtiness of vanity for immediate satisfaction; of this the outcome is a deliberate sacrifice of the abiding appreciation of the intelligent for the transitory and noisy clamour of the unintelligent and shallow, with the fatally sure result of a paralysis of the sense of self-respect, a lowering of standard, and, in the end, an impotent disinclination for every sustained and serious effort. Other failings there are of which, as I said, the bearing is not so immediately evident, but of which the dangers are scarcely less. As one instance of

these, I will quote the indulgence in a narrow, unsympathising spirit, a spirit ever awake to carp and to cavil—feeding its self-complacency on the disparagement of others. This spirit stunts and shrivels those who yield to it, and by blinding them more and more to the work and beauty that are in the work which is not their own, deprives them of the priceless stimulus of a noble emulation. Let me urge you to avoid this pitfall also, and rather to keep alive within you a generous temper, ever keen to see the good wherever it may be found, finding and fastening on it as by instinct in the least promising surroundings, even as a divining-rod strikes on the hidden spring under a parched and weary wilderness of sand; for of this temper you will gather the fruits tenfold in the work of your own hands. And now, before closing, let me recapitulate the points on which, in this rapid and too summary glance at the bearing of ethics on art, we seem to have established our position. We have laid down as an unassailable axiom that the special function of a mode of expression is to convey those ideas, emotions, or impressions of which it is the fittest vehicle, and we have recognised that the proper vehicle of purely ethical ideas is speech. Art, on the other hand, we said, being the proper and only channel for impressions of another order—namely, æsthetic impressions, cannot have for its highest duty the conveying of ethic truths. We saw, further, that though the impressions which it is the exclusive privilege, and therefore the proper function, of art to convey are primarily æsthetic, they are very complex in their nature, and receive an incalculable accession of strength through the operation of associated ideas; and again, we saw that these complex impressions in which intellectual and ethical elements are thus added to the fundamental æsthetic sensation, having, like those stirred in us by music, the power to raise us to the highest regions of poetic emotion, deserve to rank among the noblest delights of men. And, lastly, we have seen that, while the inculcation of moral and religious truths must be admitted not to be the object of art, as much, nor moral edification its appointed task, it is not therefore true, as some would have us believe, that the artist's work is uninfluenced by his moral tone, but rather that the influence of that tone is, in fact, upon it, and controls it from the first touch of the brush or chisel to the last. And once again, I say I would fain stamp this vital fact deeply in your minds. Believe me, whatever of dignity, whatever of strength we have within us will dignify and will make strong the labours of our hands; whatever littleness degrades our spirit will lessen them and drag them down. Whatever noble fire is in our hearts will burn also in our work, whatever purity is ours will chasten and exalt it; for as we are, so our work is, and what we sow in our lives, that, beyond a doubt, we shall reap for good or for ill in the strengthening or defacing of whatever gifts have fallen to our lot.

At the close of the President's address on Saturday last, the students assembled in the Antique school, and presented Mr. Pickersgill with three handsome silver salvers, and the following address signed by over 100 students:—"Sir,—We, the past and present students of the Royal Academy of Arts, desire most respectfully to offer this testimonial to you as a mark of our full appreciation of your valuable teaching, and the unvarying kindness that you have always shown to us as students of the schools during the time you have so worthily held the office of keeper. We sincerely trust you may long remain amongst us, and we rest assured that both we and those that follow will alike reap the benefits of your valuable counsel and advice." Sir Fred. Leighton, the President, and other members of the Royal Academy attended the presentation.

BARNACLES.

AT the third ordinary meeting of the Architectural Association, held on Friday evening, Mr. Cole A. Adams read a paper entitled "Barnacles." The President, Mr. Aston Webb, occupied the chair. The author said that amongst the many definitions of the title of his paper set forth in dictionaries, he should take that of the shellfish often found adhering to ships' bottoms, and utilise it as a vehicle for a talk with his fellow members on some subjects

which, although not novel, were ever of value and importance. Amongst the other good qualities of the crustacean referred to (continued the lecturer) he pre-eminently has one which should commend itself to our serious attention. No matter what subject he attacks, he invariably goes to the bottom of it with a persistency and method which are highly to be commended. This necessity for going to the bottom of any subject the student takes up is apparent, provided the study is one worth the labour. If so, this barnacle faculty of sticking to it cannot be too highly commended. Prof. Roger Smith insisted on this very strongly in his remarks made at the last meeting of the Association on the subject of the compulsory architectural examination. It is such a temptation at the present time, with so much passing before our notice, only to dip into a subject, to look up the particular matter we are in need of, to skim books, and, if working for an examination, to cram into the stomach of the brain more than it can possibly digest. No profession, perhaps, includes in its many ramifications such an enormous number of subjects as ours. Almost every day brings to the man in practice, and, in a lesser degree, to the assistant and pupil, fresh difficulties to be met, fresh topics to be looked up, fresh problems to be worked out. Now it is decoration; now a peep into some sewer difficulty; now the valuation of a house; now the designing of one. The architect is called on by Mr. A. to find out why the damp will come through a certain wall and at no other part of the house; by Mr. B., as to whether he can raise his house without involving himself in a lawsuit with Mr. C.; is choosing wallpapers with Mr. D., and the next hour discussing the most recent sanitary appliances with Mr. E. Then there are endless interviews with Mr. F. as to the exact position of this, that, and the other. This variety in the practice of a general practitioner is not without its charm, even though it has its worries, and among them that complex instrument of torture, the builder's account. Now if we follow the barnacle habit of getting at the bottom of each difficulty, the gain will be enormous. The result of study of this kind is most salutary, as we accustom ourselves thereby to habits of thoughtfulness, to weigh first the answer before it is given, not to accept what can be proved without some demonstration. This mode of working must be prepared for early, and happy is the student who falls into hands capable of guiding his studies. Though the difficulties that face him are greater than those that formerly existed, the advantages in some degree keep pace, as knowledge is brought almost to his door. The battle is year by year becoming a harder one, so many barnacles having the same aim, but the secret of success in the race is with the hare than with the tortoise. Cultivate therefore the habit of dealing with one subject at a time; it will give a breadth and power to the mind which will stand you in good stead. The difficulties which beset the modern architect who aspires to hold a high position in his profession are Herculean. In those ages when the art was a living one, and it was natural to build in one style, with all the life and surroundings in harmony with it, the task of designing must have been an easier one, comparatively speaking. Doubtless there were new schools of thought, variety of design, but it ran in the same direction, was academical, governed by fixed laws and principles? Now, what chaos reigns, what confusion of styles! The student looking abroad is bewildered, and has to put on "barnacles" to assist his mental vision. Sorrowfully he looks back over nigh half a century when men saw, that Gothic was fair to look upon, and notes how with enthusiasm the study of it was taken up, and the appetite for it "grew with what it fed on." Men were then terribly in earnest in their efforts. He may smile at much that was done, but he cannot but love those who are gone and respect those disciples who have through good and through evil report followed their beloved art. The battle of the styles was fought on a bloodless field, and all the belligerents have claimed the victory. Now this great Gothic wave has spent itself, has done its appointed work, and a restless nineteenth century craves for other food. But a few years back he would have been a bold man who dared to lift his voice in this room and say that, after all, there was much to admire in Wren's churches, and that a student might do worse than study Luigi Jones's work

at Whitehall. We have grown wiser now, and in art very liberal. Of faith there is but little, and scarcely any enthusiasm. We must regret that a certain indifference has sprung up, and that men are pandering to bad taste, and working in a No-style in which belief is wanting. Architecture has caught a kind of scarlet fever, and has entered upon a phase of its history which may be called the Rubbed-and-Red-brick era. For ecclesiastical work, Gothic still claims the larger share; and we possess new buildings which show an extraordinary advance upon what was done a few years back in their greater breadth and freedom from fussiness. The details of cathedrals are not stuck on parish churches; large plain surfaces are left to tell their own tale—to suggest repose, to heighten features and detail. Simplicity of plan and parts, and a greater knowledge of designs, as they appear on paper and in execution, characterise much that we see rising around us. In the prevalent red-brick styles there is much that is lovable; and when its features are kept within bounds, great piquancy of effect, as well as dignity, may be gained—although where the sketch-book is utilised without a definite purpose the result is confusion. In the hands of its greatest master the popular style has much one cannot help liking, spite of oneself; but what are its principles? In too many cases it is but a continuation of senseless features—of wide openings covered with a flat arch so thin that it could not hold itself up alone, and itself carried by a concealed iron girder, painted to resemble wood-work; memorial tablet detail; porches stopped off at the bed-mould of the cornice—these and other eccentricities commonly seen are barnacles that eat into the very life of architecture, and bring it and its practices into ridicule. Is this work that will make the student honest or truthful in what he does? Will its study enable him to "design with beauty, build with truth"? No. But what is the young barnacle to lay hold of? Something he must stick to, or sink. One great lesson to be learnt from barnacles is that unity is strength. By himself your barnacle is a very insignificant creature; but he is a member of a body bound together by very strict ideas of unionism; and so powerful is combination, that it can impede the progress of the largest ship. This pattern of consistency of action is not one to be followed in resisting legitimate progress; and even in relation to the barnacles, it is suicidal, as they are hacked off the vessel's sides before long. But without carrying the figure to extremes, we see that singly the barnacle is powerless; combined with his fellows, he is strength—a principle too much ignored by architects generally, but well exemplified in the Association. Again, conceit in the young is a parasitical barnacle, which gathers quickly to itself other barnacles, and gnaws into the vitals and hinders the progress of the man. No better mode of clearing these is to be found than in measuring one's strength with that of others in the classes. It would seem to be the tendency of modern times to subdivide labour, and more and more we see that specialism is spreading. In all other professions we note this sub-division of labour, and there are signs, not to be disregarded, in our own. Church restoration and church building are for the most part in the hands of comparatively few men; this is more notably the case when the church to be restored or built is in the hands of a committee, and many a mau, probably every bit as competent, is set on one side because Mr. Somebody else has been fortunate enough to be better known as a church restorer or builder. Again, in school, workhouse, and hospital building, in sanitary engineering, alas! here as a profession we have ourselves to blame. Much that would come to us, we have as a body turned from as beneath our serious notice. This work and much else has drifted into other channels, and is no longer thought by the public to belong to the profession of architects. Does it not, therefore, behoove us to look well into this matter, and if specialism is to be the modern order of things for a young man to consider carefully where his particular bent may lie, and then to turn his special attention in that direction, after carefully weighing his future prospects, if he has any, of getting work? To do this, there can be no doubt that a general study of his profession will be the wisest course to pursue; but, with a definite aim before him,

he will cultivate more assiduously that particular study which will fit him for the place he desires to succeed in, and, taking a leaf out of the book of the young barnacle, will devote his energies to getting a firm grip of it, going beneath the surface and making himself master of the situation. Specialism of all kinds has a tendency to become cramping to the intellect, and tyrannical in its effects; on the other hand, in the liberal and mechanical arts, we find and must recognise that men whose whole time and energies are devoted to special branches, in painting and sculpture, or the making of particular machines or articles of manufacture, attain a precision and accuracy which are very remarkable, and seemingly only attainable by such a system. In medicine and surgery, we see essentially this system of specialism; and in our sister profession of engineering we have its members devoting themselves to separate and distinct subjects, and obtaining in each the most marvellous results. But architecture, which is as old as the hills, is more conservative. Most of us hitherto in practice have laid ourselves open for each and every thing that might come in the way. But our masters, the public, are becoming more critical; art education is telling its tale, and clients look about for themselves, look with discriminating eye before they decide upon whom they will employ, and often choose the man who has given special evidence of his capacity to meet the requirements which they need. Do we not ourselves use this discretion? Formerly we went to the general medical practitioner for every ailment, but now if it is within our means we go to the man whose reputation lies in healing the eye, the liver, the lungs, the brain, rheumatism, gout, and the many other ailments flesh is heir to; and then in surgery how many are the divisions? Certainly here the system seems to work well; certain it is that the public think so too. No jealousy exists in the profession, and science is undoubtedly advanced by the powers of the mind being devoted to the mastering of one subject. Engineering, too, as we have noticed, includes branches too numerous to mention. It would seem, then, only natural in the order of things, that in our own profession we shall see the same barnacle action taking place. If with the spread of knowledge, of science, and of art we are to hold our place before the world, it must be as men proficient in what we undertake. So numerous now are the various works that the architect is thought to include in his work, and be master of, that it is simply impossible in the time at his disposal that he can be a proficient in all of them. Work of every kind and description connected with architecture is daily being filched from us, and men and companies are started for doing that which would be better done by architects, who, trained in youth to the profession, elected a particular branch or branches to practise in. Our work is frequently done by men who have only a slight acquaintance with the art and science of architecture, and professional architects too often get the blame. If, instead of this, special branches were taken up by men educated as architects on a broader basis, I think we should see much the same result as exists in the medical and other professions, and we should have a class of specialists who could be called in in consultation by their professional brethren as necessity arose. The advantages to be gained by this system would seem to be this. The profession of architecture would stand better in the eyes of the public by the proficiency of men in its various branches; work connected with building, &c., instead of drifting into other quarters, and being done by men who have little or no knowledge of architecture, would be kept in the profession and be looked upon as belonging to it. A slight acquaintance with the work of outside specialists is enough to show how hideous they can make the work they touch, and how in their desire to make their own work successful, they disregard all considerations of art. But already the public is alarmed at the expense of sanitary reform initiated more particularly by these specialists, and the accounts we hear of the cost involved are sometimes startling. Now we have this matter a good deal in our own hands, and much else, such as warming, ventilation, &c. A general knowledge, at all events, of principles and practice, is essential to every practitioner; but if we had more men like those who read papers and spoke upon the subject of sanitation,

&c., last session, we should be able in any difficulty, with the consent of our clients, or on our own behalf, as the case might be, to call in one of these gentlemen to advise. Now, there would be nothing *infra dig.* in such a course, for it is done in other professions. A feeling of *esprit de corps* would animate the consulting and consulted architect, and the advice would be given with a knowledge of the whole case and all its difficulties, both working in the same interests for the benefit of the client. Again, in special matters of construction, design, decoration, and what not, the same system could be adopted more than it is now, to the great gain of the profession and the public. And the esteem of the former would be increased, if our employers found that we contained in our ranks all the elements for meeting whatever question arose without going to outsiders for information, and involving them in large extra expenses thereby.

There are barnacles and barnacles. Some spend their lives at home, others are great travellers, but beyond sustaining the life that is in them, apparently gain little advantages from this mode of spending their lives. So there are students and students. Some, from necessity or inclination, stay at home, and some are fortunate enough to be able to travel and visit many countries. The pursuit of the beautiful is a necessary study for all who aspire to the highest qualifications of an architect, to be, before and above all else, an *artist*; but, to make use of his studies, he should not only be a sketcher of what will look pretty in his sketch-book, but should observe the object upon which his attention is turned, and try and discover in it what was the motive of the man who executed the work, the materials of which it is composed, the colour which charms, and how this pleasurable effect of colour is produced, whether solely from the kindly hand of time or intentionally. Then the plan,—generally one of the most important factors,—the mode of construction, the height from the ground and from where viewed and intended to be viewed. Now, all this necessarily takes a long time, and nineteenth-century rush so pervades our modern system that few will take this trouble. To pursue such a course of study will not fill the sketch-book, and is too irksome. We often place too much importance upon the sketch-book as a show-book. I remember, some years ago, when seeking employment, showing my sketches to a very distinguished architect. He was kind enough to compliment me upon them, but added, "I should better like to see them loaded with figures." There is no doubt of the wisdom of such a course. Your drawings will not look pretty, but you will have facts to correct fancies, and I think no one who adopts this course regrets it. You see some pretty little piece of architecture, sketch it, gloat over it, and show it to your friends as something very choice. Years after you wish to refer to it; then, may be, your recollection of its plan, situation, and construction, the materials of which it was composed, are gone from you. Now, had all this been noted down and measured, the system, though laborious, would have impressed it upon your mind, and your drawing would have been of greater use. So great is the importance of such a course of study known to be by those qualified to judge, that the prizes for sketching old work are mainly based upon the principles enumerated. A favourite maxim of the late Mr. William Burgess was "Sketch and measure, measure and sketch." The neglect of this thorough way of sketching is the cause of a great deal of weak and senseless detail in modern building. The rambling method will leave the student a travelled barnacle, with little real professional gain. The habit of thoughtfully working out one subject, and mastering it, is worth a bookful of "bits"; it conduces to an increase of reasoning power by going to the root of the matter, which, when we are at work upon designs for our own buildings, gives method and reason for what is produced. It is an absolute necessity in early years to pursue this system, as by it experience is gained, the student learns to discriminate and to jot down all the salient points of his study, and to economise labour upon it, but only after many years of toil and a peculiar faculty which some possess above others for grasping the essential, and showing only what is absolutely necessary to express this to yourself and others. Mr. E.W. Godwin's method

of sketching old work may be quoted and pointed to as illustrating my meaning. Another useful way of making foreign travel of real use is the habit of keeping a concise and careful diary. It is, of course, rather irksome, but of the great advantage of so doing there can be little doubt. This occupation teaches a student to express his thoughts and ideas intelligibly, practising him in composition, and gives a habit of observation and a facility of expression which in after years will be of enormous advantage in writing reports for committees, papers to be read before such bodies as ours, and, may be, books to be published. Work to be done on the spot, whether sketching or writing, is conducive to habits of accuracy, and is of a value hardly possible to exaggerate. Let us now consider "barnacles" in their nature of parasites, of which they are a species. The practice of architecture is not free from parasitical growth, and its progress is often impeded by it. In our day one great danger has arisen from the excessive prominence given to draughtsmanship and perspective drawing. The art of photo-lithography, whereby the actual handwork of the artist can be reproduced in fac-simile, has been an immense gain; its cheapness offers great advantages, and men have not been slow to seize them. The development of pen-and-ink drawings has largely fostered the production, and we have in our profession some exceedingly clever masters of the art. The professional journals have almost universally adopted photo-lithography for their illustrations. Most men like to see their works in print, and the facilities now offered for achieving this are so numerous, the demand so great, that it is not surprising that a large supply has followed. Now, valuable and useful as all this is, it is to be feared—and you will remember that Prof. Kerr warned us against the danger—that young men, seeing the ease with which they can get their works thus copied, devote the greater part of their time to making pretty drawings, and obtaining excellence in the mechanical and artistic use of the pen, and this, to the exclusion of more useful studies in the art and science of their profession. To be a good draughtsman is to possess a power which will stand the student in good stead; but if it tempts him to make pretty sketches and designs, elevations and details, which will not work, are not constructive, or are not the outcome of that primary necessity of all good architecture—a well and carefully-considered plan—then such work is not true architecture, but a parasite. We are too apt, so critical have we become nowadays in this matter of draughtsmanship, to lay too much stress upon the drawing and too little upon the design as a whole; and there has sprung up a class of specialists who undertake this class of work, and who can design elevations by the yard and make impossible perspectives, and if by chance we see works so represented carried into execution, we hardly recognise them. Useful, too, as perspective drawing is, the same tendency to exaggerate its use and to deceive is very noticeable.

One of the greatest encouragements to showy drawings has been the competition system. The man who goes in to win a competition knows perfectly well that his chances of success generally lie in producing a fine set of drawings. It is not, therefore, much wonder that this should beget a race of draughtsman-architects who know how to tickle the fancies of the Dogberries and their companions by designs for buildings which cannot possibly be executed for the money as designed, and which, if chosen, have to go through the mill and be ground down and thinned. The competition system, as too generally practised, has favoured the barnacle growth to an alarming extent, and the good ship Architecture has been much hindered in her course in consequence. Happily much of this evil has been remedied, and it is, fortunately, becoming the custom to call in a professional assessor to advise committees. Many of us are looking forward with some interest to see what the Council of the R.I.B.A. are going to do in the matter of the memorial presented to them last year, followed by the report of the committee specially formed for the purpose of formulating a scheme for the better conduct of competitions. The matter is one of serious importance to the profession, and the barnacle cohesion given to the memorial was a proof of the interest taken in the matter, and how keenly

men felt the injustice of the system as generally carried out. If the appointment of a professional assessor is the *sine qua non* of all respectable architects consenting to join in a public competition, the death-blow will be given to the profession and e-ling of paper architects. No one in his senses is sanguine enough to suppose that the appointment of a professional assessor is the panacea for all the evils of the system, but fair-play is a jewel, and every man who knows his work and loves uprightness will feel that in the hands of a man of honour and skill, his design will be judged, as far as fallible human nature can judge, on its fair merits. Barnacles, you have observed, attach themselves to an object on the underside of it: are, in fact, out of sight, so that one does not notice them. If you will take the trouble to look you find them, or you may "nose them" if their habitation has become stranded high and dry. This habit of the barnacles brings me to another part of my subject to which they must serve as an illustration. Foundations, timbering, drainage, sanitary appliances and water-pipes, bell-wires, &c., are out of sight, often below the surface, and veritably it may be said of many an unsavoury smell, "You shall nose him as you go up the stairs into the lobby." I would impress upon students the positive necessity of making themselves acquainted with the subject of sanitation. It is too much the fashion among enthusiastic young architects to ignore this branch of their work. Well, at first sight it is unavowry, dull and dry, and perhaps much of it is nasty. It is not a light art; but as you must come down from the sky and lower the tilt of your æsthetic nose, the neglect of the study, and mastering of its rudiments at least, will beget a growth of barnacles which will assuredly impede your progress to the shores of success. A few years back, and most men left all this seemingly unpleasant work to the builder or clerk of the works. Science, with her powerful barnacles on, has peeped into the hidden mysteries of health and impediments to health, has found out causes against which medicine is powerless, and has discovered that they arise, almost invariably, from neglect of nature's laws, and that the seeds of disease and death are frequently to be found sown in the house we live in. The note of alarm has been raised, daylight has flooded in upon the hidden horrors, and they have been revealed in all their bare hideousness. We know now that death has been taken into the home, and sewer-gas is responsible for much misery and disease. We know this now, and it is simply criminal in any of us who are called upon to design buildings if we neglect the warning. Make yourselves masters of your arts; but, neglect this, leave it to others to do in a kind of haphazard way, and you will most assuredly find that the opportunities of displaying your designing powers will be limited to paper and to your own offices. "Be sure you see to the drains," is over and over again the remark that you are met with by your clients. You will come across men thoroughly up in the principles of modern sanitation. You will, at the outset of a job, be asked what you advise; how you propose dealing with this problem, this or that soil, this or that system. If you answer, "My dear sir, you surely don't expect me to go into such matters; that matter is for the clerk of the works or the builder"; you will fall a great many degrees in the opinion of your clients; you will harm the profession to which you are proud to belong; you will give cause for the remarks one so often has thrown in one's face, that architects are impracticable people, and do not know their work. This and much else has drifted from the profession, because we have hitherto too much neglected it, and a race of sanitary engineers has sprung up to do it instead. To ignore this class of work is so very foolish. Suppose a young architect, just established in practice. He must not expect to be building mansions all at once: he is called in for some small alterations, say some revision of the drainage system is needed. If he can undertake this, and achieve success in it with careful thought and still more careful superintendence, he will win the confidence of his employer, and add to his chances of procuring more work. Now, supposing he allows his ideas of the fine arts being the exclusive rôle of the architect to prevail, and that his soul is not to be worried by such "unconsidered trifles" as drains; the

probabilities are, he will disgust his employer, who will politely but firmly get rid of him on the first opportunity, and thus a chance of success, a step upon the ladder, has been lost. Clients are right in making us careful; the lives of those nearest and dearest to them may lie in our hands, and they will not be clean, if through carelessness and wilful neglect of what is now patent to any engineer, we neglect the warning and go on blindly disregarding all the lessons of the past. A paper treating of impediments to the progress of architecture would hardly be complete without some allusion to that great feature of modern times, speculative building. Here, barnacles of every kind and degree congregate, and, unchecked, hinder and impede all true progress. Naturalists tell us that the young barnacle is cyclopean, and makes use of his one eye to find a resting-place, and, pouncing down upon the first favourable one, there establishes himself. And then quickly and with wondrous growth and fertility shall houses gather all around him, until he has covered every available space with his progeny. Is not the speculative builder similar somewhat in his habits? His one idea is gain; he fixes his eye steadily upon some favourable spot, attaches himself to it with a firm grip, and then quickly covers the land with his creations, gathers to himself a whole host of other barnacles, until we no longer recognise the site he has covered. A parasite of the parasites is speculative building as too generally practised. It would be most unfair to gibbet thus all speculative builders. I only allude to the disreputable class of speculative builders who prey upon an ignorant public. They are not alone blameworthy. Feeding upon them in their turn are the owners of the land they settle upon, who exact terms which are a premium upon dishonesty. Then, again, there are lawyers, and, it is to be feared, surveyors too, of a certain class, who fasten upon the unfortunate builders and suck them nearly dry. And, lastly, a greedy public, who grind them down to the lowest farthing. Architects in their professional capacity can do little to remedy the evil. They are seldom consulted, beyond occasionally supplying plans, and except in the better class of speculative building, never are called in to superintend the carrying out of them.

At the close of the paper a short discussion ensued on the points of specialist architects, the new order of competitions, and other points raised in the paper, in which the Chairman, Messrs. Harcastle, Vacher, and James Smith took part, and a vote of thanks was passed to the lecturer.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

AT the annual opening meeting, held in the Society's rooms at 7, Westminster Chambers, Victoria-street, an address was delivered by Mr. Arthur T. Walmisley, Assoc. Mem. Inst. C.E., the president for the ensuing session. After alluding to the steady progress made by the Society since its establishment in 1856, and its value to the younger members of the profession, Mr. Walmisley observed that the problems with which engineers had now to deal were so varied, and the competition so keen, that a vast field of knowledge had to be covered by their professional education. He believed that the want of employment, complained of by so many, was in the majority of cases due more to their own incompetency than to the overcrowding of the profession, and to enable us to compete with foreign rivals it was necessary to avail ourselves of every opportunity to keep our knowledge up to the day. Ample facilities existed in our scientific societies and collegiate institutions to obtain the necessary education, and he hoped the time was not far distant when an educational test would be established, upon the basis of which the engineering profession would for the future be constituted. As things were, any one might call himself a civil engineer, while to be a solicitor or a doctor it was necessary to pass through the usual examination. The Institute of British Architects and the Institute of Surveyors were about to establish such tests of proficiency, and he hoped that the Institution of Civil Engineers which contained among its members the representatives of all branches of constructive science, would soon rescue the profession from its present state of undefined profi-

ciency by establishing an examining board with power to grant such diplomas or certificates as would be recognised in the profession as a proof that the holder has attained to a certain standard in his knowledge. The Civil and Mechanical Engineers' Society was in no way opposed to the Institution of Civil Engineers, nor had they any idea of rivalry with the Society of Engineers, but they met together as a social society to review the past, consider the future, and to assist each other professionally in every way.

Referring to the progress of modern engineering, which he mainly attributed to the competition between the various railways and steamship companies, Mr. Walmisley said that the increased size of our newest ocean steamers had necessitated the construction of new docks, or the enlargement of the existing ones, at nearly all our seaports—as, for instance, at Leith, Liverpool, Hartlepool, Swansea, Penzance, Cardiff, Folkestone, Milford, Hull, and other places, while London herself had now under consideration great additions to her dock system. After describing the advantages of the new Victoria Docks and the proposed Dagenham Dock, Mr. Walmisley alluded to the scheme promoted by the East and West India Dock Company for the construction of deep-water docks at Tilbury. It was intended to give due prominence to the provision of ample quay area by the construction of jetties, and to have branch lines running along the same connected with the London and Tilbury railway system, which would enable goods to be conveyed by rail to and from any of our commercial centres by means of the great trunk lines of the kingdom with which the Tilbury system is connected. The plan also included the construction of two graving docks, each of the length of 900 feet, which would be capable of sub-division as might be required to dock long and short vessels together, separated by means of transverse caissons sliding in grooves.

At Barrow a floating dock was being built in iron, which would be capable of accommodating vessels of 2,300 tons burden. The peculiarity of this dock would be the possibility of dividing it, if necessary, into two equal parts, each with its own separate engines and pumping machines capable of docking the other half, and of depositing a vessel high and dry on a stage for the purpose of cleaning and repair. He considered the Naval and Submarine Engineering Exhibition, to be held next April at the Agricultural Hall, and which he was pleased to see well supported, would be productive of much good, and that the Electric Light Exhibition, to be held at the Crystal Palace this month, would not only show what had been done towards perfecting this light, but would lead to further achievements in electrical science. The Smoke Abatement Exhibition, held at the Albert Hall, showed what had been done in the science of economy towards obtaining a maximum of heat with a minimum of fuel. All this tended to show that engineers were intimately concerned with all the great improvements of the day. Civilisation was a very difficult word to define, but included all that engineers had done. When we heard that such-and-such an undertaking did not pay to work, it was the duty of the engineer to step in and devise such appliances that with careful working a fair profit might be counted upon in executing the same.

It was to the engineer that the public looked, more than to anyone else, to suggest suitable undertakings for investment.

A vote of thanks was unanimously accorded by the Society to the President for his address, and seven new members were proposed for election.

The parish-church of Bergh Ayton, Norfolk, was reopened on St. Andrew's Day, after restoration. Two unsightly galleries have been removed from the transepts, and the nave has been refloored and provided with new benches, pulpit, and reading-desk, all of oak. A brass altar desk and corona of the same metal have also been placed in the chancel. A new window, filled with cathedral glass, has been opened out in the south transept. The contractor was Mr. Morris, of Ditchingham, near Bungay.

The distribution of prizes and certificates to the students in the Maesteg science and art classes took place in the new town-hall on Wednesday week. The report showed that during the year 29 Queen's prizes, five honour certificates, and 83 certificates were gained, maintaining the high average of the past five years.

ILLUSTRATIONS.

DOMESTIC STAINED GLASS.—ST. WILFRID'S CHAPEL, AND THE MAGDALEN CHAPEL AND ALTAR IN THE ORATORY, SOUTH KENSINGTON.—RESIDENCE AT BLACKHEATH.—CHANCEL ALCH, LINCOLN ABBEY CHURCH.

OUR LITHOGRAPHIC ILLUSTRATIONS.

DOMESTIC STAINED GLASS, DE VERE GARDENS, KENSINGTON.

A DESIGN shown on paper as a drawing, but seen in execution as a transparency, requires a little consideration of the difference between the action of reflected and transmitted light upon it. In the first case, breadth and repose are required, but in the second, unless coloured glass is employed to a great extent (which is not the case in the present instance), one of the essential conditions to insure a good result, is that the white glass should be entirely covered with equal and regularly painted detail, to soften the glare and harden. The foregoing remarks are intended to apply only to grisaille consisting of ornament, and not to figure-work, for which coloured glass should be used, as the conditions of equality and regularity of design are not in that case possible. A grisaille composed entirely of white, or more correctly of colourless, glass, although it may be rich and velvety from the detail applied, has a vibrating and restless appearance. The introduction of coloured glass, in the form of occasional bands, or other forms, will remedy this defect, and the painted ornament on these bands has the effect of checking the radiation of one colour over another (very considerable in the case of blue) and of giving increased richness to the tints themselves. The windows that form the subject of the present illustration have, with others, been executed for Sir Daniel Cooper's house at De Vere Gardens, Kensington. The panels, with fruit, flowers, and musical instruments, are in "warm white" rolled glass; the design, stained yellow in parts, is on a semi-transparent dark ground, from which a pattern is taken off, before firing, with a pointed style. The narrow borders are in white, mixed with colours, principally ruby, flesh-red, yellow, and olive-green. The geometrical patterns in squares, shown by rather fine lines, are clear glass, outlined with fine brown lines on a ground of white mat, which gives an opalescent effect, contrasting well with the transparency of the rest of the glass. The landscape in the opening in centre circular-headed window is leaded up in coloured glass, the rest of the window being treated similarly to the others described. Nos. 1 and 2: Library, centre, and one of the side lights. The Leads in the centres are in execution as Shakespeare and Chaucer—although shown as two female heads on the drawing. No. 3: Back drawing-room, centre light, the window having three lights (the two side lights are not shown). The heads of "Poetry" and "Music." No. 4: One of the staircase windows. No. 5: Lobby between stairs. No. 6: Lower half of entrance-hall window (top half not shown).—W. H.

THE ORATORY, BRIGHTON.—ST. WILFRID'S CHAPEL. By the kind permission of the Fathers of the Oratory, we are enabled to give our readers an

interior view of St. Wilfrid's Chapel, which is now being erected under the direction of Mr. Herbert A. Gribble, on the vacant plot of ground at the north-east corner of their new church, and connected with it by an opening from the transept. In length it measures over 60 feet, interior dimensions, and in width, at the centre, over 30 feet. It has a small cupola at the top, carried by four monolithic columns in Breccia Scavazza, standing on marble pedestals. This chapel will eventually be adorned with a series of fresco and mosaic panels, illustrating important events connected with the early English Saints. The panels in the cupola will probably be devoted to the saint to whom the chapel is dedicated, while the four pendentives may contain portraits of St. Edward the Confessor, St. Edmund the Martyr, St. Etheldreda, &c. And on the walls and ceiling will be depicted such subjects as the introduction of Christianity into England by St. Augustine, the martyrdom of the Sts. Thomas A'Becket, Edmund, and Alban; the offering of the Crosier to St. Cuthbert by the King of Northumbria, the Confession of St. Theodore, and others similar ecclesiastical subjects. The remaining portion of the walls will be embellished with painted grotesques similar to those of the Vatican loggia by Raphael and Julio Romano. The chapel contains two confessionals, arranged as seen in the view, an Italian marble altar, and a small organ gallery, and through the medium of the sliding door this apartment can be cut off when desired from the body of the church, for special services, &c. Mr. George Shaw, of Westminster, is the contractor for the works, the quantities being supplied by Messrs. W. H. Smith and J. Lee and Son, surveyors.

THE MAGDALEN ALTAR.

AMONG the many altars necessary for the new Oratory Church, this one occupies not the least important position, being situated in one of the central side-chapels, which is surmounted with a copola and top-lighted, and dedicated to St. Mary Magdalen. It is 30 feet square and 50 feet high to the sill of the lantern, and is provided with two large recesses for confessionals and a corresponding number of niches for colossal statues; the illustration shows the proposed method of treating the background with plaster and mosaic panels, portraying incidents in the life of the Saint. The altar, with its accessories, will be executed in Plymouth marble, as follows:—Commencing at the floor-line with black, the dies of the lower pedestals in a sample resembling that known as "St. Anne's." The dies of the upper pedestals will be of green, with red and grey panels, while the capping and base mouldings will be in yellow—a marble very little known and somewhat scarce; it is rich in tone and slightly brecciated with small pieces of grey limestone, which impart a very agreeable and interesting effect. The four large columns, which are about 11 feet in length, will be in breccia spar of a semi-transparent nature, having a variety of reddish hues and other tints. This is the first occasion that this stone has been used for purposes of columns, as it is necessary that the quarry should yield blocks of large dimensions, which it promises now to do most favourably. The caps and bases are in Carara (seconds), and the superstructure in an arrangement of the samples already mentioned. The centre picture of the saint, prostrate at the feet of the Cross, will be in Venetian mosaic. The altar-front will be fitted with a large plate glass panel with a brass frame, inclosing a sarcophagus containing the ashes of St. Euphrasie. The contract for the marble-work only is at present settled, and is being executed by Messrs. Goad and Co., Plymouth. The plastering, the floor, the altar-rails, and the mosaic still remain for future consideration.

RESIDENCE AT BLACKHEATH.

THIS house, which has been recently erected for Mr. J. F. Green, of Blackwall, is situated on a portion of the estate of the late Mr. J. Penn. The walls are of red brick, with red and black tile hangings, and the roofs are covered with dark tiles, parts of the exterior being in half-timbered work. The principal staircase as well as the whole of the internal wood-work of the dining, drawing-rooms and library, is executed in American walnut wood, the ceilings being carried out in the same material with panels in low relief. The windows are glazed with lead lighting throughout, with ornamental glazing

in the upper part of the drawing-room lights. The entrance-hall is laid with parquet. One special feature of the design is the position of the kitchen, which has no rooms over, and the flue from which (with a large ventilating flue adjoining) is boldly carried up in the front. The works were carried out by Mr. Havill, builder, of Lee, from the designs of Mr. W. J. Green, architect, of London. Our illustration is taken from a drawing by Mr. G. R. Julian, which was exhibited at this year's Royal Academy Exhibition.

LINCOLN ABBEY.

LINCOLN ABBEY is situated in Kirkeudbrightshire, about a mile from the town of Dumfries, the capital of the neighbouring county, and on the opposite bank of the Nith, which divides the two shores. Like a great many religious houses, its site has been well chosen amid pleasant scenery; it stands at the junction of the Cluden with the Nith, and it is from the smaller stream that the name is derived, Lincluden meaning the pool of the Cluden. The original buildings were erected about the middle of the twelfth century by Uchtred, Lord of Galloway, as a Benedictine convent. About the close of the fourteenth century the convent was suppressed by Archibald the Grim, Earl of Douglas, on account of the misconduct of the nuns. The church was erected, other additions were made, and the buildings transformed into a college, and by the name of the "Auld College" the ruins are frequently spoken of in the neighbourhood. The college, with its lands, belongs now to the Maxwell family, one of whom, in defiance of law, caused Mass to be celebrated within its walls for the last time in 1585, shortly after the Reformation. I do not know how many agencies may have contributed to the ruin of the buildings, but certainly the hand of man has been the most active instrument of destruction. Of the church nothing remains but the walls of the chancel, south transept, and about three windows in the south wall of the nave. For a long period it has suffered much from the wanton mischief of visitors, the opportunity afforded by the carved work for acquiring excellence in all the niceties of stone-throwing having been widely taken advantage of. A few years ago an iron gate was fixed to close the entrance to the chancel, but to the juvenile and mischievous portion of the visitors this obstacle only formed an excuse for clambering over the rood-screen in order to gain admission to the interior, sometimes that the more imaginative of them might pursue a vain search for a mysterious subterranean passage, which, according to one of Miss Jane Porter's novels, passed under the river and connected the abbey with the castle of Dumfries. This fiction, so attractive to youthful explorers, referred not to the present church, but to that which preceded it. Within the present year the ruins have received more attention, and excavations have been undertaken with a view of clearing away the rubbish and fallen masonry and revealing the extent of the buildings. The mouldings and details of the church are bold and massive; the sedilia, the piscina, and the beautiful mural tomb are, however, marked by more minute and elaborate ornamentation. The tomb, which in the illustration is visible through the entrance, was erected about 1440 for Lady Margaret Douglas, a princess of Scotland, and the daughter-in-law of the Grim Earl to whom the abbey owed its transformation. I have some sketches and measured drawings of the tomb, which I may one day forward to you. In almost every instance the hood-moulds of the windows are terminated with shields carved with the arms of families who have been connected with the college, the bloody heart and three mullets of the Douglas being frequently quartered with others. The heavy cornice over the chancel entrance has been decorated with two rows of carving, the upper representing cherubs in the act of adoration, and the lower showing various scenes from the life of Christ. The significance of the latter could be dimly recognised a few years ago. No woodwork remains. The walls have been built with the red sandstone of the district.—W. CANNING.

Plans for a new town-hall are to be prepared by Mr. G. S. Bridgman, of Torquay, and it is hoped that the building will be erected with as little delay as possible.

"BUILDING NEWS" DESIGNING CLUB.

DESIGNS FOR MODEL COTTAGES.

WE have received so large a number of designs for this subject that it will not be possible for us to examine every one of them or with the care we should have given. Owing to this we have divided the number into groups, and shall confine ourselves to the first and second of these as nearly as possible in the order of merit. (1) "Beta" has produced a simple block of cottages under one steep roof. The plan is nearly an exact square, with the fireplaces arranged in the centre, and the entrances at the sides; there is a small hall, 7ft. by 6ft. 6in., partly occupied by a stairs with winders, opening from which is the living-room on the front side, 15ft. by 11ft., with a scullery opposite the entrance, 12ft. 6in. by 8ft., separately entered, which is not necessary. There is a ladder in the recess formed by the hall and stairs, and a back-door to a small yard, in which the earth-closet, coals, and ashes are grouped together. There is a good front bedroom with cupboards, and two smaller bedrooms behind. The simply-treated tile roof, and the windows are shown in an unpretending and cottage-like manner. (2) "Self Help" is also simply and artistically treated, though of rather more expensive character, owing to the gables and centre gutter and the extra valleys of the roofing. The entrances are also at the sides, a small lobby projection, which is carried through, giving access to a living-room, 14ft. by 12ft., in front, with small square bay; leading out of which at the back is a kitchen, with sink, &c., while along the side, behind the lobby, is a small pantry, a fuel-closet and an e.c., the last having the door on the outside. The author thus obtains all his offices under the same roof. Upstairs are three bedrooms, the back ones being each 10ft. 6in. by 9ft., and the front one 12ft. 6in. by 11ft. 9in. A linen-closet is shown on the landing. The plan is compact, and the area covered small. The elevations are in brick, tile-hung above, with timbering in the gables; these are half-hipped, and the details are in a plain Old English Vernacular style, the chimneys being brought together and pleasingly grouped above the roof. The mullion and transom windows are characteristic. (3) "Ignotus" is a neat pair of gabled cottages in a plain Gothic style, brick below and tile-hung above, with timbering in the gables. In the plan, the author has a side-recessed lobby entrance, the inner wall of which forms one side of an angle or fireplace in the front room, in which is a seat. The living-room is 14ft. by 10ft., and a cupboard is obtained below the stairs, which latter is made to ascend from the scullery. It would have been better reversed. There is a store, the fuel and closet being outside. The bedroom plan is economically arranged, and the upper walls are of stud-work, tile-hung, with timber-work to gables. The details of gable, windows, and interior wood-work are in good taste and well drawn, and the cost is put down at £380 per pair. (4) "Ben." This is a neat pair of brick and tile-hung cottages, plainly treated externally: the entrances are at the ends in front; there is a little recessed lobby to each, entering a living-room of good size, with a small projecting scullery behind, and a small yard with offices. The pantry is obtained under the stairs, which ascend from the front room behind the entrance. The bedrooms are narrow and are all small. Details are suitable. (5) "Melton" is also very compact in its arrangement, and the two cottages form a square block roofed in one. The entrances in front, at each end, have small lobbies, and each gives access to a living-room, 12ft. by 12ft., with a scullery, pantry, and coals, and tool-closet behind, very economically planned. There is one good bedroom, and two small ones. The stairs are closely arranged in a small compass, lighted, but rather cramped. The detailed elevation and section are boldly drawn in a suitable cottage style without unnecessary ornament, and the whole is intended to be of brick and stucco. (6) Cross in Circle, is a neatly-designed elevation, exceedingly quiet, and unobtrusive in its features; the cottages are under a span roof, with tile-hung gable dormers over the upper windows, and brickwork to the lower story. The plan is simply contrived. A corner lobby leads into a living-room 15ft. by 13ft., with a scullery behind, out of which at the side the stair ascends. A fuel-cupboard and a pantry

are shown beneath; the upper plan is spoilt by the narrow bedrooms in front. The details are neatly drawn in a good style. (7) As usual, "Nemo," whose work we are glad to see again, has sent in a clean and neat set of drawings. The cottages are rather more expensive in character than we intended. The entrances at the sides form projections in the plan. The lobby is rather large, with a stairs leading to the bedrooms above, all of good size. The pantry, fuel-store and e.c. are obtained in the side projection, all under the same roof, and easily reached from scullery. The latter is entered from the lobby, and there is no door from living-room to it—a plan which may do for a small villa, but is not desirable in a country labourer's cottage. The plans are neatly figured and drawn, and the details are designed in a domestic Gothic style, mainly in brick. The gables in front would have been better simplified. (8) "Try" in Shield shows a different arrangement of cottages: the entrances are not on the same front, but in opposite sides, a plan which would be difficult to adopt in some sites. The elevations are in a simple brick-and-tile Domestic style, and a single-span roof is shown over the pair. The separation of living-room from scullery by the centre lobby entrance is not economical, as it entails labour in preparing the food and in cleaning. The detail of porch is effective. (9) In "Pupil J." we have an old hand again. The grouping of the gables and the placing of the pent-roof doorways, one in front and the other in the side, are good points in this plan, but the stairs in the side gable lobby appears hardly to have headway under the roof. The living-rooms and sculleries, with pantry and coals under stairs, and the bedrooms, are suitably planned and of good size, and the area covered is small. The elevations are proposed to be of grey brick, relieved by quoins, strings, and arches of red pressed brick; the casements to be of cast or wrought-iron, and the workwork painted of a dark green. Details are plain and suitable. The estimate is worked out at 5d., equal £408. (10) "Ars Longa" is another economical plan: the cottages are comprised in a rectangle with all the offices under the roof. There is to each a small recessed lobby entrance and side stairs, access to which is from the living-room, a rather small scullery behind with large coal-store, and e.c., a compact bedroom plan, with the flues all collected together into one centre stack. The roof is not satisfactory, and the ventilating gable-ends and valleys are costly. In other respects the author has produced an appropriate design; the walls are shown hollow, with plaster in upper story. All rooms are proposed to be ventilated by flues formed in walls with outlet and inlet (11). "Folle Farine"—This is a neatly drawn Gothic design, with rubble walls and flag slating for roof, well adapted for a stone district, though the author shows an alternative elevation for brick, rough-cast, and weather tiling for a brick locality. One of the entrances is in the front, and the other on the side; the left-hand arrangement is preferable, and less expensive; the side lobby has too much of the villa character about it. The sketch is pleasing with the slight corbelling out of upper windows. (12) "Edmund" is a front of red brick and weather tiling, quiet in treatment and inexpensive, but the porches placed together in the centre is not desirable; the stairs look cramped, and the upper arrangement does not give one good bedroom. The yard behind the living-room and the scullery rather spoils the scullery and offices, which appear crowded. Economy of area has been aimed at. "Fidelis" (Sigma) is sensibly treated. The entrance lobby and stairs in front are compact; but the former would better have started from the living-room, as being less open to dishonest people and vagrants. The elevations in plaster and brick are plain and suitable. "K." shows side porches, and also access to stairs from outer lobby—undesirable points. The coals would have been best placed within doors. In other respects the plan has merit. "Junior" is appropriate in elevation; but the stairs would be dark at the top, as no window is shown. The lean-to porch is not a desirable feature, and the breaks in the plan and roof are objectionable and costly, particularly the centre gutter. "Hugh" is a compact block, but the stairs face the entrance, which is not desirable. The offices are compactly planned, and the elevations are suitable and modestly

designed in brick and tile. The author shows cavity walls and well-adapted window details. "V." in Circle is neat in the drawing; but the elevation is of a too pretentious character, more adapted for a small villa. The central open porch is not a judicious plan, and is likely to become a source of mischief with gossiping tenants. The stairs look rather cramped, and the chimneys on the outer walls entail cost. The overlapping bedroom is rather open to objection; the doors of living-room and scullery would also have been more comfortable if not placed in so direct a line. "Deva" is a simply-designed block of rubble, with side gables and oak timbering—a rather curious mixture. The stair and lobby arrangement is somewhat awkward, and the scullery has no access from living-room. The offices are not neatly planned; the coals are awkward to get at. "Veritas Vincit" has a compact economical plan: the stairs project, but ascend from the living-room; the pantry and coals are well placed at the side of scullery, and the e.c. and dust outside. The upper landing is in a small bedroom. In external design it is less happy, and the upper windows are depressed by the eaves of roof, which might have been avoided by dormer gables. "In Hoc Signo" is spoilt by the centre entrance; the bedrooms are small, and the centre projecting windows and roofing are not good. "C." in Circle has angle entrances with brackets, rather weak in appearance; the stairs are placed in side projections, and the general planning and design have merits. Some good points also strike us in "D. T." in Circle, but the separate doorways and middle gutter are not desirable features; "Iota" is too ornate; the timbering is heavy, the stairs on one side have little headway, and are badly lighted, despite good points. "E.B." has a bedroom on the ground-floor and a living-room divided by the stairs, which is poorly lighted. The yard and offices, which from side wings are small, and the upper windows are depressed by the projecting eaves of roof. Why such deep brackets to the eaves?

We have received a number of designs having arrangements often based on economical principles, and worked out with considerable knowledge of the requirements of cottage building, but the external treatment of which fall short of our standard. Of these the authors must be content if we point to defects. "Old England" is spoilt by awkward hipping of roof; "Spes," expensive middle gutter; "S.D." in Circle, rooms not intercommunicable, fireplaces in bad position, and expensive in timbering; "Fiat," too villa-like and wasteful, offices in centre, costly porches; "Triangle in Circle," economical plan spoilt by centre windows, which misrepresent the requirements; "Hall," compact in plan, but commonplace in elevation; "L." in Circle, extravagantly ornate in elevation; "Will," appropriate in elevation but harder too large; "Economy," compact, but pantry and outer offices awkward; "Bycullah," neat in elevation, separate doors from hall unnecessary; "H. D.," snug arrangement, but rather bald in elevation; "Mustapha," expensive entrances, and pantries not in convenient positions; "One of Them," open to the same objection, harder too large; "Adventure" is closely planned, but is cut up by bay-windows and gables. We name also "Spur and Win," "Student M.," "Justice for Scotland," "Benachie," "Sam Slick," "Opus," "Economy" (2), "Finem Respiece," "Dum Spiro Spero," "Toledo," "Dado," "Simple-Minded," "To be, or Not to Be," "Random Shots," &c. "K. E. S. W.," "Hal," "Norman," "Yarra Yarra," "Oliver Twist," among these who have fairly interpreted the requirements in general design, but who have not been so happy in working out the details. A large number of designs aim too much at display, and in plan have rather taken the small villa or cottage one as their model. We may enumerate "Good Luck to Your Fishing," "Sleights," "H." in Circle, "Hubert," "Exegi," "Oaks," "De Grey," "Ernest," "Merit," "To Be, or Not to Be" (2), "Rollo," "Gobo," "Truth," (well drawn), "Darby and Joan," "Gable End," "Hal" (2), "Sine Qua Non," "Francis," "Damian," many of which exhibit meritorious plans, though others show a want of simplicity in the arrangement, or a multiplicity of breaks on the plan, which lead to complications in the roofing, and the use of unnecessary valleys and gutters. For a labourer's cottage the

simpler the roof is the better. These designs chiefly fail in the elevations, and some of the designs show an extravagant display of ornamental timber framing, gables, and barge-boards.

Another group of designs fall short of the requirements in both plan and design, and it is impossible to do more than to name the best of them. Of these, "Trial," "T. Carre," "Nil Desperandum," "Eos," "Nero," "Circle in Square," "Beamstalk," "Sol et Sentum," "Tristram," "Fred," "Pallium," "T. F.," "Circle," "Ambition," "Ars Longa Vita Brevis," "Tom Finch," "Ever Onward," "Gemshorn," "E. D.," "in Circle," "Dum Spiro Spero" (2), "Jek," "West Countryman," "Tempus Fugit," and "Broad Oak" may be mentioned. The other designs received, some showing careful drawing, will be noticed under our correspondence.

SMALL STAIRCASE.

The designs we have received for this subject are hardly up to the mark. An effective plan is by "Quid"; the bottom stairs are made to turn and project into the hall, with a screen to stop the windows opposite drawing-room door. The details of arch and first floor are in keeping, but the drawing is barely finished. "Hugh" sends one of the best drawings, but the plan is not the most effective, and the commencement of stairs might have been improved. The doors are of good design, old English in style, and painted green. "I fain would climb, &c." is an elaborate attempt in Elizabethan of a florid type; the bay-window recess at bottom of stairs, the hat-stand, and kitchen-door are well placed. "Cross in Circle," "Ever Onward," are also appropriately treated. The other designs are too elaborate in detail, or have missed the object we had in view—an architectural treatment of a small villa staircase limited in area.

LECTURES ON ARCHITECTURE DELIVERED AT THE ROYAL ACADEMY.*

THE lectures delivered by the late Professor Barry at the Royal Academy from 1874 to 1880 have been published by Mr. John Murray, and make a portly octavo volume. They have been revised and edited with an introductory memoir by the Rev. Canon Barry, the memoir comprising an account of the life and chief works, public and private, of the author. With the merits and scope of the lectures our readers are not unfamiliar, as they were reported from time to time in our own pages. It is only according them justice to say that they were mainly introductory to the study of architecture, and did not attempt to enter into the theory and practice of the art, as those delivered by the late Sir Digby Wyatt or Sir Gilbert Scott, which have already been published. They sought rather, as the editor says in his preface, to steer clear of architectural technicality and detail, and to deal with architecture chiefly in its relations to other branches of art, and to the requirements and interests of modern life. Viewed in this light, Professor Barry's lectures may possibly be read with some advantage by students preparing to make the profession of architecture their vocation.

The series, as now published, has been arranged by the Rev. Dr. Barry in better order than it was found desirable to deliver them: the first series deals with general principles, and the second with historical examples. Ten lectures are devoted to the consideration of the first subject, and thirteen to the history of the art. Some of the passages, serving only a temporary purpose, have been omitted, and repetition, almost necessary in oral addresses, has been avoided, while we find more coherence has been given to the lectures by the insertion of marginal headings. With regard to the illustrations, they have been confined chiefly to typical plans of well-known buildings, such as that proposed for the House of Commons by the author, plans of Longlat House, Crewe Hall, St. Paul's Cathedral, St. Peter's at Rome, and various other Gothic, Italian, and Renaissance examples, and some of these have been reproduced from Mr. Fergusson's handbook. It is unnecessary to retrace the ground covered by the late Mr. Barry in these lectures or to make any lengthened observations upon them. The author, in his earlier lectures, deals with much justice

on the financial difficulties under which the architect now works. The "nicely-calculated less or more" is one of the conditions which hamper the composition of great works of art, and there have been probably few modern architects who have been able so fully as the author to realise the restrictions imposed by pecuniary and utilitarian considerations. In reading the memoir of his brother prefixed to these lectures, we can understand how thoroughly Mr. Barry's experience, in connection with Government works and in recent competitions, tended to strengthen his convictions on this point. The union of scientific knowledge and artistic ideas, the constructional difficulties in building, the variety of conflicting interests, such as the archaeological, the scientific, and the purely artistic, are made the themes of very useful and sound advice, and Mr. Barry is constant in his enunciation of the many-sidedness of the architect's profession. The fascinations of purely archaeological views of architecture, or those mixed up with questions of religion and ritual, are held up as matters against which the student ought to be on his guard. A just sense of the relation of architecture to Nature and humanity is made the theme of the second lecture, and we find many incidental references to questions of an æsthetical and physical kind. The development of science is prominently introduced in connection with art, and the author, unlike many occupiers of the chair at the Academy, is not remiss in showing the necessity of widening the studies of the architect, and in reconciling the apparent hostility existing between science and engineering with art. The interdependence of the professions of the engineer and architect is forcibly brought forward, and Lecture IV. discusses the double aspect of architecture as a fine art and an art of utility. In another lecture the technical principles of the art are considered, the need of technical study by the architect, the element of size and its effect on the mind, the value of scale, and the author brings forward as examples of it the Coliseum, the Roman baths, the Gothic cathedrals, and the French portals. The principle of apparent as well as real stability, the value of a base-line, the subject of construction, and the use of materials are next discussed. Lecture VI. deals with proportion and ornament, and the next with architecture allied with colour, in which examples are brought forward to show the use of external polychromy in Classic and Italian buildings. Mr. Barry expresses just doubts about the practice of veneering walls with thin slabs of coloured marble—a method which concealed real construction. The difficulties attending the employment of colour in the London atmosphere are not overlooked, and the author boldly admits that unless our urban atmosphere can be purified of smoke, external polychromy is scarcely within the practical sphere of English town architecture when ordinary materials are used. Lectures VIII. and IX. discuss the application of general principles to practice, and the question of competition and its value to the young architect, are considered; though the author observes with truth, the value of an artist's work can only be measured by its sincerity. Restoration and the position of the architect towards it are made the subject of remark, and the author has grasped the philosophy of the matter. One of the most practical and suggestive lectures of this series is the last, on "Town Architecture and Modern Problems." The dwellings of the middle class—on the principle of co-operation or flats—are amongst the topics discussed, and the author asks whether it is not possible to remedy existing evils and still retain the English separate house principle, or to establish economy of service on the co-operative system, and still retain the habits of life dear to the Englishman. Mr. Barry's suggestion for combining separate houses with common offices in town-squares, is clever. The square has a large basement, containing the kitchen, laundry, baths, wash-houses, reading-rooms, gymnasium, stores; above which it is laid out as a garden, and each of the houses surrounding it have the benefit of the central kitchen. The last series take up the historical view of architecture, and the lectures embrace early military architecture; domestic architecture of the 12th, 13th, 14th, and 15th centuries; English Transitional architecture, or Elizabethan, illustrated by several typical examples, English Renaissance, Italian Renaissance, &c.

The introductory memoir will be read with interest, as affording a view of the career of an architect whose connection with important Government undertakings, and large private practice led him into the front rank. The select competitions for the New Law Courts and National Gallery are of course dwelt upon, no less than the anguish and disappointment that they brought to Mr. Barry during the closing years of his short but active life.

THE BRIGHTON HEALTH CONGRESS.

THE Exhibition of Domestic and Sanitary Appliances and Health Congress at the Royal Pavilion Brighton, was opened on Tuesday. The work of the Congress was inaugurated by a meeting in the Dome on Tuesday night, under the presidency of the Mayor of Brighton, when Dr. B. W. Richardson, F.R.S., delivered an address on "The Seed-Time of Health."

The sectional proceedings commenced at eleven o'clock on Wednesday morning in the Dome. The President of Section A., "Health of Towns" (Mr. Edwin Chadwick, C.B.), took the chair, accompanied by the President of the Congress (Dr. Richardson), the Mayor, and other gentlemen.

Mr. Edward Easton, C.E., F.G.S., read a paper on "The Brighton Corporation Water-works." Brighton, he said, was situated in the midst of a considerable extent of chalky country, and possessed an excellent water supply. It had previously been supplied imperfectly from a well sunk near the Lewes-road, but in 1865 a well was sunk at Goldstone Bottom. The number of houses supplied in 1851 did not exceed 7,000; the number now on the rate-books was about 24,000. The area of the district was, as nearly as possible, seven miles from east to west, about five miles from north to south. The plan had been adopted of dividing the district into four zones or services, each fed by its own reservoir, or reservoirs, with its own system of main pipes. All the zones were connected. The town was supplied both on the intermittent and constant system, and Brighton was now in the position of being able to give constant service to one house and intermittent to the house next door in the same street. The pumping power at Lewes-road was between 130,000 and 150,000 gallons an hour, and Goldstone Bottom 150,000 gallons. The total quantity of water pumped during a year was between 1,100 and 1,200 millions of gallons, equal to about 3,200,000 gallons a day.

Mr. Edwin Chadwick delivered the opening address of the Section, "On the Prevention of Epidemics." He set out by describing the various means adopted to stay the great outbreak of cholera in 1848, in which he took a prominent part, and stating the deductions made from observations then taken. The conclusions that had then been arrived at were that to aggregate disease in a large hospital was a source of danger, and that the very best means of preventing the spread of infection was by the adoption of sanitary measures at the places where, in the cycle of epidemics, they were to be expected. He described in a very interesting manner the precautions taken at York, at Merthyr Tydvil, at Mevagissey, and other places, and the gradual decrease of deaths that followed, and he showed that similar precautions taken at St. Petersburg, Malta, and Memphis had produced the same results. At St. Petersburg, for example, the deaths had decreased from 25,000 to 3,000 in the successive decade. Some other equally startling statistics were given by Mr. Chadwick. By the returns of the Local Government Board, he calculated that we had saved in the death-rate, from diseases of infection, a quarter of a million of lives and three million cases of sickness, and putting these at a money value of £5 for a death and £1 for a sickness, over four millions of money had been saved. He came to the following conclusions:—That cases of small-pox, typhus, and of others of the ordinary epidemics, occur in the greatest proportion, on common conditions of foul air, from stagnant putrefaction, from bad house-drainage, from sewers of deposit, from excrement-sodden sites, from filthy street surfaces, from impure water, and from overcrowding in foul houses. That the entire removal of such conditions by complete sanitation and by improved dwellings is the effectual

* Lectures on Architecture, delivered at the Royal Academy, by the late EDWARD M. BARRY, R.A., Professor of Architecture. London: John Murray.

preventive of diseases of those species, and of ordinary as well as of extraordinary epidemic visitations. That where such diseases continue to occur their spread is best prevented by the separation of the unaffected from the affected, by home treatment if possible; if not, by providing small temporary accommodation; in either case obviating the necessity of removing the sick to a distance, and the danger of aggregating epidemic cases in large hospitals, a proceeding liable to augment the death-rates during epidemics. That skillful and complete works of sanitation and the removal of conditions of stagnancy and putrefactive decomposition are the most efficient means of reducing the expenses of excessive sickness and death-rates.

Dr. Mackey read a paper "On the Geology and Climate of Brighton, from a Health Point of View." Taking the last fifteen years, the mean temperature stood at Brighton at 50deg. in the shade; the Greenwich mean for 60 years 49.1deg.; that at Plymouth for 15 years was 51.6deg., and at Eastbourne for a short period, 51deg. Thus it would be seen that the average of Brighton was slightly higher than Greenwich. The popular idea that autumn was the best time for Brighton was perfectly correct. The mean winter night temperature of Brighton was, at least, 4deg. warmer than that of London.

Dr. Fussell, Medical Officer of Health for East Sussex, read a paper "On the Necessity of Recreation Spaces in all Large Towns."

Mr. E. F. Griffith read a paper "On the Escape of Gases from Ventilating Covers in Towns." He pointed out the evils which existed both in defective house-drainage and the construction of many sewers, and said the nuisance caused by smells prevailed even in towns drained within the last 20 years upon the best-known sanitary principles. He attributed this to bad workmanship, remarking that the sewage discharged into the sewers was frequently putrid from remaining in joints, and, therefore, caused smells to rise into the streets.

Mr. E. B. Ellice Clark, Town Surveyor of Hove, read a lengthy paper "On the Administration of the Sanitary Laws;" and, after two other addresses, Mr. H. F. Lester, B.A., closed the day's proceedings with a paper "On a Reform in Slaughter-Houses," dwelling on the need for sweeping away of private slaughter-houses, and urging the necessity for public establishments under perfect inspection, and also the desirability for devising a mode of putting animals to instantaneous death without pain.

In the evening a *soirée* of the Association was held in the Congress Rooms.

Yesterday was devoted to proceedings in connection with Section B, "Food in Relation to National and Domestic Economy." The President, Mr. John Robert Hollond, M.A., M.P., delivered an opening address, and this was followed by others by Dr. C. Daysdale, on "Cheap Food and Longevity"; Mr. Lightfoot, on "Preservation of Food by Cold"; Mr. T. W. Cardan, on "Honey as an Article of Food"; Miss Yates, on "Bread Reform"; Mr. Winter Blyth (Medical Officer of Health for Marylebone), on "Rational Feeding and Eclectic Diets"; Dr. Whittle, on "The Artificial Dieting of Infants"; Mr. H. S. Mitchell, M.A., on "Lessons on Foods and their Preparation for Schools"; Major F. F. Hallett, on "Food-Plant Improvement."

In the evening, an address was delivered by Mr. R. P. B. Taaffe, M.D. (Lond.), C.S.S. (Lond. and Camb.), Medical Officer of Health for Brighton, on "The Propagation of Disease, through Food and Drink."

To-day (Friday), Section C. (Domestic Health, including Educational Training) meets under the presidency of Dr. Alfred Carpenter. After the President's opening address, papers will be read by Mr. H. H. Collins, F.R.I.B.A. (Secretary Health Dept. Social Science Association), on "Home Sanitation"; Prof. Fleeming Jenkin on "House Inspection"; Mrs. King on "Health in Relation to Clothing"; Mr. W. H. Hallett, F.L.S., F.S.A., on "Domestic-Softening of water from the Chalk"; Mr. E. Bailey-Denton on "Domestic Filtration"; Mr. C. Cassal, F.C.S., on "Health Lessons in Schools"; Mr. H. Stephens, F.C.S., on "An Aspect of Public Elementary Education in Relation to Health"; Mr. L. B. Tuckerman, M.D. (Cleveland, Ohio, U.S.A.), on "Health in Schools"; Mr. R. Scott Moncrieff, C.E., on "The province of the Physician and the Engineer in the Work of

Sanitation"; Dr. Strong on "Hints on Domestic Sanitation," and Mr. R. W. Edis, F.S.A., "On Sanitation in Decoration."

To-morrow, Saturday, December 17th, the Congress will close with a lecture on "Eyesight," to be delivered in the Dome by Mr. Brudenell Carter, F.R.C.S., at eight o'clock p.m.

A NEW SCAFFOLD CRANE.

MESSRS. F. W. REYNOLDS and Co. are the sole licensees and makers of Hurst's Patent Scaffold Crane, which we illustrate here-

with, which seems a handy labour-saving machine for builders and contractors.

It may be quickly fixed, may be used with any sized pole, and can be used either stationary or swinging by reversing the bottom collar. The difficulty of finding a suitable fixing for a block and fall which interferes considerably with this method of raising building materials to the height required, is obviated by the invention illustrated, as the Patent Scaffold Crane can be fixed to any pole in a few minutes. Should the pole be too small for the collars, these may be secretly fixed by wedges.

These cranes are forged of the best S.C. crown iron, and can be made to any size desired.

CHIPS.

The Metropolitan Board of Works on Friday formally approved a Various Powers Bill to be introduced next session. Its objects are to enable the board to make by-laws regulating the traffic over the bridges and on the embankments, to extend the Tooley-street improvement, to authorise the transfer to the board of Peckham Rye, and the acquirement of lands adjoining Tooting Beck Common. A Bill for the amendment of the Metropolitan Management, Buildings, and Thames River (Prevention of Floods) Acts was also approved, but a clause limiting the height and distance from streets of timber stacks was only agreed to on the casting vote of the chairman. At the same meeting it was resolved to invite six firms to tender for the execution of works to the foundation of Waterloo-bridge, Sir J. Bazilgette recommending this course in preference to inviting open tenders.

The east window of St. Mary's parish-church, Antingham, Norfolk, has just been filled with stained glass. It consists of four lights, which are now occupied with the Nativity, the Crucifixion, the Resurrection, and the Ascension of our Lord. The work was carried out by Messrs. J. and J. King, of St. Andrew's, Norwich.

Amongst the prizes distributed on Friday evening to successful students in the technological examinations of the City and Guilds of London Institute, were a silver medal to C. W. Mesurwell, of Glasgow, in iron and steel manufactures and in oils and colours; and bronze medals to J. W. Clarke, London, and J. J. Rawlings, plumbers' work; and W. E. Dalby, tools and mechanical engineering.

A new schoolroom attached to the Unitarian chapel, Ipswich, was opened on Tuesday week. It measures 51ft. by 22ft., and seats between 200 and 300 people. Mr. Farrow, of Ipswich, supplied the plans, and Mr. Wyatt was the builder.

Two medallion lights have been placed in the east window of St. Matthew's Church, Thorpe Hamlet, Norwich. The work, which has been executed by Messrs. J. and J. King, of Norwich, is of 13th-century character, and represents the parables of the Talents and the Labourers.

Mr. Eynals, of Rochford, Essex, was last week elected surveyor to the highway Board of Malling, Kent.

No. 50, Eastcheap, containing 1,655 superficial feet, was let by auction by Messrs. Philip D. Tuckett & Co., of 101, Old Broad-street, on Wednesday last, on building lease for 80 years, at a ground-rent of £1,200 per annum.

Building Intelligence.

ABINGDON.—St. Nicolas Church, Abingdon, originally founded in the time of William the Conqueror, but subsequently enlarged by Nicolas de Coleham between 1289 and 1307, having fallen into great decay, has been repaired and restored, and was re-opened on the 26th ult. The church consists of a nave and chancel, having a west tower, built partly upon the west wall and partly upon two stone piers or legs standing clear of the walls, similar to the oak posts of some old belfries. The addition of an organ chamber and vestry with warming cells under, have been made. A curious feature of the church is that it stands partly on the arch or bridge over the little river Stort, so that, in fact, the water of the stream runs stealthily and noiselessly under the feet of the worshippers. The nave roof having become very much dilapidated, it has been necessary to entirely renew it. This has been done with English oak, trussed rafters of the same scantling as the old, and there are three oak tie-beams, king posts and braces replacing three old ones, the ends only of which were discovered when the roof was being taken off, for the beams had been ruthlessly cut out in order to plaster the ceiling. The roof is covered with plain red tiles, and an ornamental embattled parapet has been erected on the south side, having carved shields and carved gargoyles. The roof now is believed to be an exact reproduction of the one put on the Church by Nicolas de Coleham nearly 600 years ago. The church has been warmed by two of Musgrave's stoves, placed underneath in air-tight chambers, and air flues specially designed by the architect. The contract was taken by Mr. Edward Williams, of Abingdon, for £1,850, but extra work to the extent of £187 has had to be executed for things which it was not easy to foresee, but none the less necessary in the restoration of an old building so dilapidated as St. Nicolas was. The chancel floor was laid by Mr. W. Godwin, of Lugwardine, near Hereford. The architect was Mr. Edwin Dolby, of Abingdon and London.

BIRMINGHAM.—The Building Committee of the Princess Alice Wesleyan Children's Home and Orphanage, proposed to be built at Birmingham, met last week in London to consider what steps should be taken towards erecting the buildings, the fund having now reached £19,000. A discussion arose as to the choice of architect; some members of the committee thought it would be wise to throw the scheme open for competition, but a much larger number spoke in favour of selecting one tried and able architect, to whom the opinions of the committee might be communicated, and who would modify his plans from time to time in conformity thereto. It was eventually decided by a practically unanimous vote to employ Messrs. Ball and Goddard, of Birmingham, who were architects for the new Wesleyan College at Handsworth, recently illustrated in our pages. The following resolutions were also adopted by the meeting, viz.:—(1) That a central block be constructed for the accommodation of 300 children. (2) That the central block shall include a common laundry, and common dining-hall and cooking apparatus. (3) That designs be prepared for a chapel to seat 600, to be erected hereafter. (4) That sites be chosen for twelve houses, each to accommodate twenty-five children, and that a complete drainage system be framed for the whole. (5) That for the present designs for two houses only be obtained. Messrs. Ball and Goddard have received intimation of their appointment.

CAMDEN-TOWN.—The buildings lately erected at the almshouses belonging to St. Martin's-in-the-Fields, Bayham-street, Camden-town, for the purpose of giving increased accommodation to the inmates, were opened on Thursday, the 8th inst. They consist of sculleries and w.c.s attached to the old buildings, and new buildings at the rear for additional inmates, an infirmary, with nurse's rooms, bath-rooms, &c., and a chapel with nave, apsidal chancel, and vestry. The works have been carried out by Mr. Edmund Toms, under the superintendence of Mr. Henry Jacques, architect. Mr. G. Chinnock was clerk of works.

EXETER.—New quarters for the officers at the Exeter Barracks are being built. They consist of a main building and two wings, and contain

a ground-floor and one story. The length of the frontage is 110 feet—against 100 feet in the old quarters—and the height 40 feet. The entire building is of red brick unrelieved by dressings of any kind, but over the openings there is some slightly ornamental brickwork. The brick of the exterior is from Wellington, and that used in the interior is of local manufacture. The only stone used is the Ham Hill of the window-sills. The quarters are surmounted by a somewhat ungainly three-faced clock tower. The accommodation provided is for ten officers and their servants. Each window is fitted with Clarke, Bunnett & Co.'s patent revolving shutters. The contractors are Messrs. Hubbard and Bevan, of Plymouth, represented by their foreman, Mr. Cole, and the building is being put up under the supervision of its designers—the Royal Engineers Department. The erection of the building for the High School for Girls has been commenced, and the work is to be completed by November of 1882. Various designs were sent in in competition for the school, and the Governors selected the plans of Messrs. Hayward and Son, of Exeter. Tenders were invited, several were received, and there was a great divergence between the figures of the highest and the lowest. The tender accepted was that of Mr. Phillips, of Exeter, at about £6,000. The work has been carried on for about six weeks, and the operations are making satisfactory progress. The structure will consist of a main building and two wings, but eventually there will probably be an addition running back from the centre, so that when completed the school will be something in the shape of the letter D. The school will stand on a terrace, its face will be towards the Cathedral, and the main approach will be by a carriage-way opening from the road from Southernhay. The frontage will be 142 feet, and the height of the school—which will consist of ground and first floors—will be about 41 feet. The building is designed in the Tudor style, and in its construction and arrangement it has a distinctly domestic character. The foundations rest on a bed of concrete. The plinth is of the grey stone from Chudleigh, but above the plinth red brick, with Doubling stone dressings, will be used, the whole being capped by a roof of Staffordshire tiles.

IRECHESTER.—The ancient Church of St. Catherine, at Irechester, with its beautiful spire, which stands on so eminent a site that it acts as a landmark for many miles, is about to be restored. The interior of the building has long been in a condition unworthy of the purposes of religious worship, and inadequate to the increasing population of the parish. A meeting of the parishioners was held on the 5th inst., when a Building Committee was elected to engage an architect for the execution of the desired restoration and repair. Mr. W. Talbot Brown, A.R.I.B.A., of Wellington, has been appointed architect for the work. Sharnbrook Church, Beds, has recently had its tower and spire restored by the same architect.

KINGTON.—The parish-church of Kington, Worcestershire, built at the end of the thirteenth century, was respected, after restoration, on Tuesday week. The old stone walls have been repaired, and the internal fittings, where decayed, have been renewed in oak. A tasteless modern window has been removed from east end of chancel, and replaced by one of three lights, in harmony with the general style of the building. The tracery of the nave windows has been restored. The tower has been strengthened, and the half-tinted black-and-white turret upon it repaired. An unsightly gallery has been removed; the plastering has been removed from the roof, which have been renewed in moulded ribs and wall plates and carved paterne. The floors have been laid with encaustic tiles, those in the sanctuary by Mr. Godwin, of Lugwardine, near Hereford, and those in the chancel and nave by Messrs. Webb, of Worcester. The architect was Mr. W. Jeffrey Hopkins, of Worcester; and the contractor, Mr. Job Stanley, of Bromsgrove, near Abbeystead. The cost has been £200.

LETTERSTON, Pembrokeshire.—This church was respected by the Archdeacon of St. David's, on the 30th ult., after considerable alterations and improvements. It was badly rebuilt some thirty years back, and nothing could be colder, more comfortless, or of worse architectural character than the interior prior to the execution of the recent works. The roofs have been

boarded and otherwise improved, and encaustic tiles substituted for the damp stone flagging. New open pitch-pine seats have been provided in the nave and stalls in the chancel, with reading-desks, Communion-table, and altar-railing. A commodious vestry has been added, one of Porritt's warm-air apparatuses supplied, and new chancel-arch, windows and doorways throughout substituted. More, however, requires still to be done when funds permit. The work has been carried out by local tradesmen, from the plans and under the superintendence of Mr. E. H. Liugen Barker, of London, Hereford, and Tenby.

MAIDSTONE.—The foundation-stone of a new Wesleyan chapel was laid at Maidstone on Monday. The new chapel will be 60ft. long and 30ft. wide in internal dimensions, with two transepts 11ft. wide by 8ft. deep. In the rear, and communicating, will be a schoolroom 41ft. by 30ft., and an infant class-room 18ft. 9in., by 13ft., can be added to the area of school-room by opening large folding doors. There will also be a class-room 15ft. by 11ft., a ministers' vestry 12ft. by 11ft. The chapel will be 19ft. high on the walls and 33ft. to the ceiling, which will be boarded over about half-way up the slope of roof. The roof-trusses will be of hammer-beam construction. Accommodation will be provided for about 400 persons on the ground-floor, and provision is made for the addition of galleries when required. The ventilation will be by means of upright inlet shafts and a Boyle's patent extractor on the roof. The latter will be inclosed in a graceful turret about 20ft. high above the ridge. The external walls will be of ragstone faced externally with random work and squared angles. The dressings will be of Corsham down and Box-ground stone. The style of the building will be Gothic of Early English type. The architects are Messrs. Ruck, Son, and Smith, and the builder, Mr. Avar, all of Maidstone.

NEWPORT PAGNELL.—The roof being covered in of the new mill now being erected for Mr. C. H. Whitworth, the event was suitably celebrated on Friday last by a supper to the men. The new mill is a plain but substantial brick building of five stories, surmounted with a bold eaves cornice supported by moulded cantilevers, the roof being covered with slates. The dimensions of the mill proper are 53ft. by 35ft., and there are five floors, which are carried by iron columns and girders. Messrs. Usher and Anthony, of St. Paul's-square, Bedford, are the architects, and the works have been carried out under their personal superintendence by the contractor, Mr. Samuel Foster, of Bedford; Mr. Tomlin being the foreman.

WINNSON.—A swimming-bath, for the use of the students at Beaumont College, has just been completed, at a cost of £3,500, from the designs of Messrs. Byrne and Cronbie, architects, of Windsor, and 303, Strand. The bath-house internally is 80ft. long, 40ft. wide, and 25ft. high. The swimming-basin is 66ft. long, 30ft. wide, with a depth at one end of 1ft., increasing to 7ft. at the other end. The basin itself is formed of cement concrete, 3ft. thick sides, and 18in. thick bottom, four parts Thames gravel and one part Portland cement, rendered inside 1½in. thick with Portland cement, and again lined with Cliff's white-glazed bricks and ornamental pattern borders. The internal walls are rendered in Keene's cement with a dado 6ft. high of Mintons' white-glazed tiles, with ornamental borders top and bottom. Messrs. A. L. Oades, of Egham, were the contractors, the general foreman being Mr. Venton.

The death occurred last week of Mr. Stephen Henry Leach, chief engineer to the Thames Conservancy Board, in whose employ he had been forty-one years. The funeral took place at Chiswick, on Thursday, the 8th, and was largely attended by members of the board and their officials, and of the Chiswick improvement commissioners and school board, of which bodies Mr. Leach was chairman.

A new Baptist chapel was opened at Ross, Herefordshire, on Tuesday week. Mr. G. C. Haddon, of Hereford, was the architect, and Mr. J. B. Kemp, of Ross, who took the contract at £2,599, was the builder. The chapel seats 500 persons, including 216 sittings in the gallery.

A new reservoir is about to be built at Pembury for the Tunbridge Wells local board. The contract has been taken by Mr. H. Potter.

COMPETITIONS.

AMSTERDAM.—The Society for the Propagation of Architecture, of Amsterdam, invites all architects to a competition in designs for an Architects' Club. The building should be free on all sides, and should measure 45 by 35 metres (say 150ft. by 116ft.). It should consist of a basement, three stories, and an entresol; the basement comprising, *inter alia*, two kitchens and three cellars; the ground-floor a parlour, two large halls, with several smaller for exhibition of designs and works of art, and of building materials; the first floor two large halls for saucers and for conversation, a refreshment and a reading-room, a library, and rooms to be temporarily let; the second floor a large room and several smaller for draughtsmen, and a store-room. The secretary's apartments should occupy the entresol. For fuller particulars we must refer to the printed programme, which may be had on application (postage paid). Designs should be sent before May 1, 1882, to the Bureau de la Société pour la Propagation de l'Architecture, Wijde Kapelsteeg No. 2, Amsterdam. The usual rules as to sealed envelopes with motto are adopted. The first prize will be the Society's Gold Medal with 500 Dutch florins (say £42); the second prize a silver medal and 300 florins (say £24); the third a bronze medal and 100 florins (say £8). The successful plan will remain the property of the society. The deciding jury will consist of three foreign and four Dutch architects. We have further received from the same society a published invitation to all stamp-engravers to compete in producing a model for a medal, to be awarded by the society to successful competitors each year. The diameter of the medal required is 3in. Besides a model of natural size, one of double size is desired; also drawings and a short description. The price of the matrix should be stated, and will be paid the successful competitor on delivery. The prizes are medals of gold, silver, and bronze. The limiting date is March 1, 1882. The society which offers these prizes was founded in 1842; it publishes a weekly journal and a large periodical work; and among other operations it describes, from time to time, remarkable old buildings, and invites competition annually for three monuments or other architectural constructions.

BAGSHOT CHURCH.—The design submitted by Messrs. Bromilow and Cheers, of Liverpool, for the proposed church in Bagshot Park, for H.R.H. the Duke of Connaught, has been selected in open competition, which took place in December last.

BOLTON.—According to the *Bolton Daily Chronicle*, at a meeting of the Borough Sanitary Committee on the 7th inst., the following proceedings of the Hospital Sub-committee were approved:—"25th Nov. Mr. Marshall Robinson, architect, attended and submitted two tenders for the work required for carrying out his plans for the Borough Hospital. Resolved, —That the Sub-committee are satisfied that his plans can be carried out in accordance with the conditions of competition." Mr. Marshall Robinson was appointed architect for the proposed Borough Fever Hospital, subject to terms to be arranged with him.

A new school-chapel was dedicated on Friday at Wotton, a district of Heavitree, itself a suburb of Exeter. The building is in the Domestic style of Late Gothic architecture, and consists of nave, chancel, vestry, and south-west porch. It is constructed of local red bricks, and the roofs are covered in by warm, coloured tiles. The reredos, constructed entirely out of old oak beams, from an ancient and recently destroyed building in the immediate neighbourhood, stands upon a boldly-moulded super-altar of red Corshill stone, and consists of three compartments, divided by ornamental buttresses. The reredos, and the super-altar upon which it stands, are the work of Mr. Harry Hems, of Exeter. The general contractor was Mr. Comings, of the same city. The architect was Mr. R. Medley Fulford, F.R.I.B.A.

There are in course of erection at Bognor a new church and monastery for the Servite Monks, or the "Servants of Mary." Mr. J. S. Hansom is the architect, and the builder is Mr. G. Huey, of Parkstone. The works now in hand will cost £6,000, and are to be finished by September next. Westwood Ground-stone, from the quarries of Randell and Saunders, of Corsham, is used for all dressings, the walls being of brick.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—The second meeting of the session was held on Wednesday last, when the chair was taken by Mr. Thos. Morgan, F.S.A. Major Palma di Cesnola exhibited a large collection of ancient Greek glass vessels from his excavations in Cyprus, showing the progress of glass manufacture. The articles were mostly of small size, and beautifully worked with the well-known radiating and wavy patterns, many of which, as was remarked during the discussion which followed, were to be found also in the Venetian glass of mediæval times. Mr. Walter Myers, F.S.A., exhibited a collection of antiquities of Continental origin. Among these were some worked flints acquired at Copenhagen, and many fine and beautiful specimens of Roman fibule and Egyptian bronzes. Mr. C. H. Compton, described some Roman Samian ware from Germany, in every respect similar to what is found in London, affording additional evidence of the fabrication of the articles in the Rhenish provinces. Mr. J. Romilly Allen, exhibited a series of drawings of Transitional Norman iron-work from churches in Shropshire. In the absence of the Rev. Dr. Hooppell, his paper on a supposed Saxon Church in North Gosforth Park was deferred. The ruins are not far from Low Gosforth House. A report was then made by Mr. Loftus Brock, F.S.A., of the uncovering of the remains of Carrow Nunnery, Norwich, by Mr. J. J. Colman, M.P. The site was all but covered at the time of the visit of the Association in 1879, and the extensive excavations undertaken have led to the recovery of the entire ground-plan of the building. It is found to agree with the general arrangements of a Benedictine monastery. The church is cruciform and has had a central tower, the bases of several of the late 11th-century columns remain, and also those of two of the side altars. The chapter-house has been a small apartment, while the day-room has been of considerable extent. A great quantity of elaborately moulded stones and carved capitals have been recovered. The lecturer's remarks were illustrated by a large plan of the remains, prepared by Mr. Alfred G. King, who has superintended the works, and who gave further particulars. A fine series of photographs sent by Mr. Colman were also exhibited. The meeting was brought to a close by a review of the recent congress at Great Malvern, by the chairman.

ROYAL SOCIETY OF ANTIQUARIES.—On Friday evening last the Royal Society of Antiquaries held its third meeting of the present session. Two papers were read—the one by the Rev. Dr. Baron, of Queen's College, Oxford, upon the Church of St. Peter, Manningford Bruce, Wiltshire; and the other by the Rev. Frederick Edward Warren, of St. John's College, Oxford, upon some Anglo-Saxon manumissions in the Leofric Missal. Dr. Baron exhibited ground-plans of Manningford Church, showing its curious apsidal termination, and also of other churches, both English and Continental, by a comparison of which he was led to claim for it a Saxon origin, though he did not ascribe it to an earlier date than the tenth or eleventh century. Dr. Baron also exhibited a curious manuscript on stenography, probably of the date of the reign of James I. Mr. Warren handed round to the members and visitors photographs of several pages of the Leofric Missal, which belonged before the Conquest to the Dean and Chapter of Exeter, but was secured by Sir Thomas Bodley for the Bodleian Library at Oxford, in which it now is.

Since the last meeting of United Grand Lodge, important improvements have been made in the ventilation of the temple, the board-room, the De Grey, the Zeland, and the whole of the rooms in which the various lodges are held. The ventilation improvement works have been carried out by the Sanitary Engineering and Ventilation Company, of Victoria-street, Westminster, who have applied their "Imperial" ventilating tubes and "Imperial" exhaust ventilators, under the direction of Mr. John Gibson, F.R.I.B.A.

At a meeting of the Leeds town council, held last week, it was decided to employ Mr. W. Hoffman Wood, building and quantity surveyor of Leeds, as quantity surveyor for any new buildings erected by the Leeds Corporation.

"To a practical man with a taste for mechanics, and the bumps of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 50c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL, Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—J. C. and Co.—J. K. and Co.—B. and J.—M. Bros. and Co.—S. L. B.—E. H. S.

S. R. (Probably as good as any: but Lockwood and Co. 7, Stationers' Hall-court, publish one or two; send for catalogue.)—A. BANKS. Possibly Trübner and Co., Ludgate-hill, would take it: if not, try G. Street and Co., 30, Cornhill.)—S. C. (12, Great George-street, S.W.)

"BUILDING NEWS" DESIGNING CLUB.

STUDENT M. (Your suggestion has occurred to us before. We cannot notice in detail every design, but do our best to group them and point out their several defects.)

—VIGNETTE. (Received.)—OAKS. (Your drawing received.)—DOL SPRING SPEAR. (Received.)—TEMPLES FOR A. (The distinguishing letter came too late. The plan is suitable for the purpose. It is not necessary to send a sketch for the country club.)

Correspondence.

PRELIMINARY COMPETITIONS.—GLASGOW MUNICIPAL BUILDINGS.

To the Editor of the BUILDING NEWS.

SIR,—If, as your correspondent, "G. W. B.," anticipates, the assessors "avail themselves of the good points, not only in the selected designs, but in any of the others, and embody them in the final instructions," thereby making them the common property of the selected competitors, their action will be quite inconsistent with the spirit and letter of paragraph 7 of the conditions, which runs thus:—"In order to obviate the possibility of the sketch designs lodged in the Preliminary Competition being made use of by the competitors who may be invited to enter into the final competition," &c., &c. If the various "good points" throughout the designs are to be noted by the assessors, and disclosed by them, in the form of instructions, to the selected competitors, the latter might as well be allowed to see the whole of the sketch designs, and call the "good points" for themselves. Such a proceeding on the part of the assessors would be manifestly unfair. It would operate unduly to the advantage of the less meritorious designs; and, if thoroughly carried out, would

bring the whole of the matured designs to a dead level.

The general lines of the final competition seem clearly defined in paragraph 25 of the conditions, as drawings to a scale of 8ft. to the inch, "in which the author's sketch-design, and no other, shall be fully matured." The restriction I have italicised is quite consistent with the issue of separate conditions for the final competition. These might refer to the amplification of the drawings, to specific information in regard to materials, modes of construction, heating, ventilating, cost, &c., &c. Believing, as I do, that the work of the final competition can thus be little more than an enlargement and amplification of the drawings now before the assessors, I hold that the selection of the best design is, virtually, in the power of the assessors at the present time, inasmuch as compliance with the terms I have quoted will render any substantial variation in the relative merits of the designs in the final competition improbable.

An opportunity thus seeming to present itself for relieving those who might so desire it from toiling through a series of what—if my conclusions are correct—would be purposeless drawings; while, at the same time, their claim to a portion of the sum offered towards expenses might fairly be recognised, led me to trouble you with my views on the subject, and to suggest a mode by which I still believe this desirable end might be accomplished without the slightest injustice being done.

Those who consider that £150, apart from the chance of the prize, would repay them for their labour in the two competitions, will, of course, be indifferent to the points I have raised.—I am, &c., A. B. C.

SIR,—Will you permit me to say a few words upon the above subject? I am desirous of showing that all do not share the opinion of your correspondent, "G. W. B." My own feeling is that these preliminary competitions are a waste of time and a mistake; in any case, however, when we see a correspondent suggesting the scaling in of competition designs to a scale of 40ft. to the inch, I think that the acme of absurdity in that direction has been reached. I was a competitor in the Glasgow competition, and, like several others, found the scale much too small for the elevations and perspective; but try to imagine the designing of a large entrance-doorway in a space half an inch square, which would have to be done on a design to the scale suggested by "G. W. B." If only the various boards, &c., would agree to do without perspectives, the most important of all drawings for showing the superiority of one design over another; secondly, do without elevations; and thirdly, accept plans only to a scale of, say, 50ft. to an inch, no doubt competitors would be plentiful. By the way, I think the Walsall School Board showed good judgment in rejecting the memorial of the Walsall architects. If architects cannot compete decently, and in a manner something like creditable to the profession, let them refrain—they are not compelled to compete.—I am, &c., G. W. S.

DUBLIN MUSEUM AND BIRKENHEAD TOWN HALL COMPETITIONS.

SIR,—I feel it is no use making any remarks upon the conditions for the Dublin competition, or even upon what I deem the unsatisfactory correspondence I had with them upon many points which the conditions either left vague or unmentioned. I remember I received replies, saying, "I had nothing to do with this," or, "they could say nothing of that." Such replies were, doubtless, well framed to get through the committee's business; but there is no need to say they were of no use (or perhaps less) to anyone who was trying to send them a good plan to meet all their requirements and conditions. Now, I must say, I looked to find "the promised architect," a well-known man; and, I may say, I expected it would either be the one who framed the Glasgow conditions, or he who built the South Kensington Museum, both of whom the profession regard as honoured men. I confess I have no intention whatever to raise a doubt of any sort about the ability and thorough worthiness of Mr. McCurdy to have confided in him the responsible post he had, "for I have not previously heard of him, or, if I have, I cannot have been deeply impressed." Now, I for one, think the committee could have stated in the conditions something about the internal

arrangements of the present Natural History Museum; for instance, they might have said whether there were more floors than one, and if so, whether the upper one was a gallery or otherwise, for the communicating block had to be designed to suit all this. And it might have saved an immense amount of time and trouble if they had said whether they preferred galleries in the various rooms or not, for some plans would be (and I know one was) nearly all galleries; whilst others, like my own, would contain almost none. "Virtually, it would greatly depend whether the competitor liked galleries or not, as to whether he had a chance of success." For my part, I think galleries uncomfortable, except very wide, and they have a tendency to be draughty, and in a "fire-proof" building they scarcely seem to apply.

Now, again, the conditions of the Birkenhead Competition are "honourable" ones; and were it not that I am trespassing upon your space too much, I would say a word of praise for them. But it seems to me the "Instructions" should have said something about the following all-important questions:—

1. As to the position of the council-chamber and committee-rooms.
2. As to whether the Mayor's rooms should come to the front or the side.
3. As to whether the large hall is preferred in the front or at the back.

For what competitor can possibly calculate the ideas (which on such matters must certainly be formed) upon all these important points, the missing of one of which may lead to a rejection?

What we want in conditions of competitions is not a prepared plan, but the leading features of the clients' desire—and one would think this was an easy matter for them to give; and yet the whole profession can, and will in their hearts, honour the Birkenhead Council, and the intending competitors will feel some confidence in Mr. Barry.—I am, &c.,

A LATELY DISAPPOINTED ONE.

Dec. 13th.

PROVINCIAL ARCHITECTS AND THE INSTITUTE.

SIR,—Instead of endeavouring to improve the status of the Institute by practical suggestions of utility, Mr. Thomas Drew, after wandering over a large field of querulous exposition, arrives at the conclusion that all would be well if the "name of every fairly competent and qualified practising architect in the three kingdoms held in his locality of practice in honest and honourable repute," were registered under the authority of the R.I.B.A.

Could a suggestion be more vague or unpractical? Imagine the court of inquiry: the, perhaps, incompetent local opinion of, perhaps, local incompetence.

Mr. Drew is scarcely within the region of accuracy in stating that there is a laborious enticement of architects to join the Institute, and having been a member of Council, it comes badly from him to sneer at the front seats occupied by that body.

A fitting commentary, however, on the unwise remarks of Mr. Drew is the fact that out of sixteen candidates, whose nomination having been recently opposed by the Council, were recommended for admission as *Fellows*, eight are from the provinces.—I am, &c.,

WILLIAM WOODWARD.

CLERKS OF WORKS.

SIR,—As a clerk of works of fifteen years' standing, I shall have pleasure in linking my name to the formation of an association, provided that its rudimentary rule-constitution is a professional society, and not a trades-union.

Permit me to further explain by mildly airing a little personal grievance. I applied for the appointment of a large board-school, and fondly trusted that my fifteen years of local credentials would prove unassailable, and was forthwith ingloriously ousted by a working foreman of joiners.

Of course, we must all have our first job somewhere, and against this new addition to our ranks I haven't a word to say, although I confess I was smarting a little as I met him this morning in the High-street, with his hats at his elbows and his breakfast-cup under his arm. Now this novice as a C.W. is, as a joiner, a trade-unionist, and can make a telling and a

sensible speech at a trades-union or any other meeting of genuine working men. I need not remind you that board-schools are paid for with ratepayers' money, and ratepayers' representatives are not always quite perfectly free from a little tinge of party devotion.

Whether our new recruit will continue to hold as a C.W. the same voice in the union as he did as a joiner, is more than I am able to tell you; but I can see how serious complications are likely to arise. Doubtless upon the building he will hold his own, as heretofore, among the workmen, certainly so among the joiners. I am not quite so sure of the plumbers and the masons, for workmen are peculiarly sensitive, not to say zealous, upon these little points. But I give him every credit for sound moral courage, and it is elsewhere that his fortitude may be the more severely tried. His late employer has a chance of becoming his new contractor, and he may feel himself in a very delicate position among his late, and his possibly yet, upon future buildings, masters.

Now the moral I would propound is that "Another Clerk of Works" must not put clerks of works and builders' foremen into the same class together. They are no more one body than are architects and builders.—I am, &c.,

ONE C.W. MORE.

SIR,—I have read with interest the communications in your valued paper by "Clerks of Works," as to the desirability of forming a society, composed of clerks of works and builders' foremen, and others who may be holding responsible situations in the building trade. It will scarcely need to be pointed out the good that would accrue to the trade by more friction one with another. At present theirs is an isolated position, each one doing his particular work for his employer.

I think that competitive examinations on construction might be held, and prizes and certificates awarded to those taking part in them, and proving themselves in the front by their works and deeds.

These examinations might be presided over by architects and builders of repute. The parties holding certificates would then be so much more valued for their skill by the architects and builders with whom they may have to deal; and it would be of great service when, by any unforeseen circumstance, they are obliged to change situations.—I am, &c.,

CHARLES SHORE.

THE SCREENS AT RODMERSHAM CHURCH.

SIR,—Accompanying your capital illustration of the chancel screens at this interesting old Kentish church (Dec. 9), reference, in the descriptive matter, is made to them as "oak screens." It may be passingly instructive to record that, at least, one and that the ancient rood-screen, was not oak at all, but chestnut. The work of restoring these charming screens was entrusted into my hands by Mr. S. Slingsby Stallwood, the architect for the renovation of the church, and after removing the paint and whitewash of successive ages from the existing fragments remaining of the uprights of the chancel screen, it soon became evident that the wood was not oak at all, but 15th-century chestnut.

Most of us are aware of the interest Mr. Thomas Blashill has taken in the subject of "chestnut *versus* oak," and the exhaustive paper he read thereon some time ago is fresh in the minds of many readers. Therein Mr. Blashill testified that in all his researches he never came across any old chestnut—on close examination all that appeared at first so to be turned out, in reality, to be oak.

As no doubt could exist in my mind that the Rodmersham work in question was veritable chestnut, in the interests of science I sent, with Mr. Stallwood's permission, Mr. Blashill a base, and after a careful and anxious investigation, he has reported upon it. Therein he says:—

"I have had the fragments from the Perpendicular rood-screen at Rodmersham Church, Kent, cut and planed. There is no trace of medullary rays visible to the eye, nor is there any sign of any pattern or 'flower' on the surface when it is cut 'on the quarter.' It is, therefore, certainly not oak. I have compared it with some pieces of wood which can be proved to be modern chestnut, and I have

no doubt whatever that this specimen is also chestnut.

"I have, as you know so well, for many years been endeavouring earnestly to find an instance of the use of chestnut in mediæval carpentry, and yours is the first I have seen. It is exceedingly interesting, and leads one to hope that other cases may be found."

Whilst upon this subject, I may add that a number of the old West-country carved coffers are of chestnut. The material has nothing like the lasting powers of oak, however.—I am, &c.,

Exeter.

HARRY HEMS.

TESTING TRAPS.

SIR,—Mr. Davies, in his article upon page 752, which I read with very great interest, says he is not in any way interested in the manufacture of traps, I beg to say that I am in the same position. When I took out provisional protection for my improved siphon-trap, I did so because I was fully assured of its value; but having since had my attention drawn to the ∇ -trap, made by Du Bois, I found it could so easily be altered to answer all the purposes of my patent trap, that I considered it useless to proceed with the patent; the trap can therefore be made by anyone, when they will find that it possesses all the advantages which I claim for it.

Mr. Davies still maintains that he has proved his points by his experiments, and refers to an adjourned meeting held on Monday, 21st November, which I certainly was surprised should have been held without notice having been given to the committee. As Messrs. Pullen have removed their scaffolding, for the present, I suppose the experiments are at an end; but in order that your readers may not come to wrong conclusions, I beg to refer to a few of the mistakes which have been made in connection with them, which are of vital importance, and which I am prepared to prove at any time, either in Margate or London:—

1st. Mr. Davies tried his basin experiments with a plunger, and compared the results with the flushing of a direct-action closet or housemaid's sink. Now why try this kind of closet with a plunger, when in practice there is no such action? The proper test of such a closet is by a pail of water or slops thrown in carelessly.

2nd. Mr. Davies had the foot of his soil-pipe dipping into water. What does that represent? Certainly nothing in general practice. Mr. Davies assured me he had tried both with foot open and closed, and found no difference in the effect. My experience, however, is very different, for I find a very much greater strain upon the trap with foot of soil-pipe open.

3rd. The great amount of drop given between valve of closet and water-line of trap.

Mr. Davies made a great mistake when he thought he was going to settle this important question by a few experiments. Why, he has only just begun. If he will try further, and just alter the length and fall of his branch pieces, he will find many conditions under which his helmet-trap will tremble for its safety unless protected by ventilation.

When I first visited Messrs. Pullen, I was certainly a little puzzled to find them untrap the ∇ so readily, and I told those gentlemen I could not understand why they could untrap it there and I could not do so at Margate—at same time, my eye caught the length of the drop at the valve-closet, and I mentioned this to Messrs. Pullen and Mr. Davies. As I was determined to satisfy myself, I went into some very careful experiments with the same arrangements as those at Messrs. Pullen's, described on page 540, and amongst others I tried the following, which will clearly prove Nos. 2 and 3 of my objections.

I fixed an Underhay's valve-closet, firmly bedded at the seating, into a helmet-trap with 1in. seal and 13in. drop, branch 12in. long with 2in. fall into soil-pipe, 27ft. long and without ventilation; the soil-pipe being open at foot. A pail of water poured into basin, and the handle raised as in ordinary practice, unsealed the trap 5 times out of 6. I then placed at foot of soil-pipe a pail of water, allowing pipe to dip into it 3in. A similar flush would only lower the water-line 1in., and we could not untrap it. We now lowered the closet, and gave a drop of 10in., that being about what it would be in practice. With soil-pipe open at foot, a pail of water, as before, untrapped every time; with soil-pipe closed, a pail almost untrapped it every time.

Now these experiments prove my assertion that the long drop is beneficial to the helmet-trap, as is also the closed soil-pipe at foot.

Mr. Davies, I know, has said in my hearing that he would never fix a ∇ -trap without ventilation if he could help it—but at the experiments on the 19th, it was asserted over and over again that the helmet was quite safe without any ventilation whatever.—I am, &c.,

DANIEL EMPTAGE, S.E.

Margate, December 10.

Intercommunication.

QUESTIONS.

[6821].—**Colour on Parchment.**—If any of your readers can furnish me with any information as to the best means of getting colour to run even on parchment I shall receive it with thanks. I have had several survey plans to endorse on deeds, and the parts to be coloured have puzzled me very much. I have mixed with gall, also tried other little things usual in general work, besides laying on the colour with great care, but of no avail, as it finishes patchy, speckled, and uneven, and if the surface is large, shows every mark of the brush, consequently spoiling the work, as far as neatness and appearance are concerned.—AN OLD SUBSCRIBER.

[6822].—**Making New Pavements.**—To what extent is owner of house property, built about two years, liable for paying in front of house, and how is charge arrived at and made? Is owner also responsible for paving to return flank wall?—H. L.

[6823].—**Width of Roads.**—I have recently removed an old hedge and bank by side of a public road and built a wall in lieu of it, setting it back a few feet. The road surveyor of the district has, however, complained that it is not set back far enough. He requires it set back 15 ft. from crown of road. Has the Highway Board any right to demand this, and if so, under what Act of Parliament; and does the Act apply to a country lane as well as to streets, and if so, cannot my client claim compensation for the strip of land surrendered?—ALPHA.

[6824].—**Floors.**—Will Mr. McLachlan, or some other reader, reply how to calculate the strength of floors? What allowance is made for the ring-bolting, and is anything allowed for the floor-boards in calculating?—ENQUIRER.

[6825].—**Surveyor's Licence.**—Does a surveyor require an appraiser's licence for taking particulars, making inventory, valuing and drawing up claim against an insurance office for damage by fire?—D. A. B.

[6826].—**Heating Apparatus.**—I should be glad of particulars of a system of heating small churches which I have seen used, consisting of a stove sunk under a grating in the floor of the building, and a flue underground leading to a chimney some distance off. Is it known as "Poult's" system, and who supplies it? Is there any limit to length of flue, and how is it checked to admit heat into building from flue? Is there no risk? What is approximate cost?—BETA.

[6827].—**Book on Dilapidations.**—What is the best book (and by whom published) upon "Ecclesiastical Dilapidations"?—S. S.

[6828].—**Granite Pavements.**—I shall be obliged to any of your readers for information as to the qualities of various granite paving-stones, viz., Welsh, Irish, and Cumberland granites, and the Cleve Hill Dials on Ludlow. Which of these kinds would be most desirable on a main road under heavy traffic, with a gradient of 1 in 100; where I wish to employ a stone at moderate cost, but to avoid any having a tendency to wear smooth or become slippery?—PEGASUS.

[6829].—**Concrete Roof.**—I have a Portland cement concrete roof, only allowing enough fall to carry off the rain; the thickness is from six to eight inches. In warm weather I am not troubled with damp; but, the colder it is outside, and proportionately warmer inside, the greater is the damp, which then accumulates and drops off. The cement is necessarily somewhat porous, but the action of the damp is greater where least to be expected—where there is the greatest fall, and is strongest of all on some exposed painted ironwork—indicating condensation as a great cause. I mention this for the information and study of savants, but wish to ask a practical question. I propose to paint or oil the exterior surface. The latter plan is well known to preserve stone; but I am doubtful of its effect on cement. Would the cement kill the oil, or the oil deteriorate the cement? I have a fancy for doing this, as it would not change the character of the work materially, and would not look shabby in a short time, and require constant repainting. If oiling would do, I presume linseed oil would be the best, but, whether boiled or not would also be a question. If painted, my idea would be to give two good coats of lead, and two or three of oil. Probably some of your experienced readers may give me and your other readers a wrinkle.—PORTLAND.

REPLIES.

[6825].—**Variation of Compass.**—EASTON.—In my reply, on page 773, for "variation in Morayshire, in 1563, being 20° 30' W.," read "23° 30'."—P. PLAYFAIR.

[6826].—**Girder.**—This would have been answered before; but at first I was too busy over the Glasgow competition, and since then I have been unwell. The girder as it should be is now shown with a diagram of forces, the girder itself is really a compound of two simple trussed girders as shown, hence the reactions of the wall act at each corner of the girder, and in the present case equally at each; if the number of joints receiving the loads were odd in number, the centre joint would have its load divided on the two walls and borne by the two lower corners, which would then have larger reactions than the upper ones. To draw the diagram of forces, first make a horizontal line CC' of such length as will represent the total load borne by the joints 1, 2, 3, and 4 to a scale of so many tons or lbs. to the inch. In the present case assume 5 tons to be carried by the girder at top and equally distributed, this would give one ton to be borne by each of the four joints 1, 2, 3, and 4, and $\frac{1}{2}$ ton direct on each wall, the last exerting no strain on the girder will therefore be no further considered. Assume for the diagram of forces a scale of 1 in. to a ton, the line CC' will then be 2 in. long, and equally divided into four parts representing the loads on the four joints also the reactions of the wall, which are also equally divided into four parts. This line is called the line of external forces. The

load borne by joint 1 is shown by CC' at top of line of external forces, that borne by joint 2 at C'C' just below, by joint 3 at C''C' and by joint 4 at C'''C'. The reaction at the left lower corner of girder is at Aa, at the right lower corner at Bb, at the left upper corner at Cc, and at the right upper corner at C'b. Therefore the polygon of external forces represented by the line CC is in equilibrium, the loads acting downwards throughout its length, and the reactions upwards neutralising each other. From the point a on the line of external forces draw ac parallel to the brace ac of girder, and from the point A on the line of external forces draw Ac parallel to the tie Aa of girder, meeting the last drawn line at the point c. The triangle Aac is the triangle of forces for the left lower corner of girder, Aa tends upwards, being the reaction on the wall, and following round ac supposing the triangle were applied to the girder, would tend towards the joint, the brace ac is therefore in compression, and still following round c, ca tends from the joint, therefore the tie is in tension; and since the forces follow round the triangle in the same direction the joint at left lower corner is in equilibrium. In the same way the triangle bAd is the triangle of forces for the right lower corner of girder, bA being the reaction of the wall tends upwards, Ad tends from the joint, again supposing the triangle of forces to be applied to the joint, ad tends towards the joint, the tie Ad is therefore in tension and the brace db in compression and the joint is in equilibrium as before. From the upper C on the line of external forces draw Ce parallel to the piece Ce of girder, and from the point a on the line of external forces draw ae parallel to the brace ae of girder and meeting the last

drawn line in the point c. The triangle aCc is the triangle of forces for the left upper corner of girder, aC tends upwards being the reaction of the wall, Ce tends towards the joint, and ca from the joint, therefore Ce is in compression and ca in tension. In the same manner cbf is the triangle of forces for the right upper corner and shows cf to be in compression, and fb in tension. From the point e in the diagram of forces draw eg parallel to the brace eg of girder, and from the point c draw cg parallel to the brace cg and meeting the last drawn line at the point g, caeg is the polygon of forces for the left juncture of braces in girder. As the brace ac was shown to be in compression, ca must tend toward the joint, and in the diagram of forces in the opposite direction to its position in the triangle of forces Aac, in the same manner the brace ae being in tension, the line ae must tend from the joint, and again in the opposite direction to its position in the triangle of forces, aCe. Moreover, cae follow round in the same direction, and, continuing this, eg will tend towards the joint, and gc from the joint; therefore, the brace eg is in compression, and the brace gc is in tension. In like manner will be drawn fhd, the polygon of forces for the right juncture of braces. We will now consider the forces in joint 1. The pieces ge and ce have been shown to be in compression, therefore, the forces tend towards the joints, and in the opposite direction they had before, an ICC on the scale of external forces represents the load on joint 1; and the three forces follow round in the same direction. Join C'g, and it will be found to complete the polygon gcC',

the line C'g being parallel with the piece C'g of girder, and showing the force tending toward the joint; therefore, the piece C'g is in compression. In the same manner C'f is the polygon of forces for joint 4, and the piece C'h of girder is shown to be in compression. The pieces Aa and cg of girder were shown to be in tension; they, therefore, tend from the joint, and in the left joint on tie-rod, in the opposite directions to those they had before. From g draw gk parallel to the piece gk of girder, and produce Ac, till it meets the last in k. A c g k A is the polygon of forces for that joint. Following round in the direction Aa, cg, gk will be found to tend toward the joint, and kA from it; therefore, the brace gk is in compression, and the tie kA is in tension. In like manner A d h k A is the polygon of forces for the right joint on tie, and k h will be found to be in compression. Since the pieces k g, g C' are in compression, and, therefore, at the joint 2 act from it, and in opposite directions to those they had before, they follow round in the same direction, as also the load on C' C'. C' C' k completes the polygon for the joint, which reads k g C' C', C' C' k tended towards the joint, therefore the piece C' C' k of girder is in compression. The polygon C' C' h k completes the figure, and is the polygon of forces for joint 3. It will be found that in each triangle or polygon of forces, these all tend in the same direction, which shows that each joint is in equilibrium. It will be also seen in the diagram of forces that there in each line read twice over and in opposite directions, which proves the whole structure also to be in equilibrium. This diagram of forces also shows that in the outer pieces of the girder, or, as they are sometimes termed, the flanges, that the strains increase in a regular ratio from the walls towards the centre, whilst on the other hand the strains on the braces decrease, so that in the centre there are none. If "H. D." will work out a diagram of forces for a lattice girder of at least 9 or 10 bays in length, he will find the above-mentioned increase and decrease of strains much more apparent. "H. D." may think my girder does not bear much similarity to a lattice girder; that, however, arises from the small number of divisions therein—if he adds one more division, the centre load would be borne by two braces, both in compression meeting at the joint, and there would be two lattice divisions on each side, instead of one as in the present case. The case under consideration shows the greatest possible gap in centre; this would occur whenever there is an odd number of divisions. The braces meeting at a joint are always, one in compression and one in tension, except at the centre of a girder when the two which meet at the top would both be in compression, and at the bottom both in tension. If any more braces were added to the girder under consideration it would be found that they would be both in compression and in tension, which is absurd. The strains can be measured off to scale.—HUGH MCLACHLAN.

[6831].—**Old Crosses in Cornwall.**—Recurring to this fascinating subject again, there is a general impression amongst thoughtful men that the old crosses, in very many instances, are of a date far anterior to that of the churches they so often stand near unto. Very probably, when a manor was first traced out, and its boundaries fixed, an open space was cleared for the transaction of business. Such village greens were called, in the Western parts, from an early period, "stows." Hence, in Cornwall, we have Morwenstow, Padstow, Warbstow, Davidstow, Michaelstow, Petrekeastow, Jacobstow, &c., &c. At these public places manor courts were held, sports were celebrated, tithing men met together, and levies were made for public service. Of course, such spots, in such times, were necessarily hallowed by religious rites, the stow blessed with the name of some favourite saint—and as a remembrance of the dedication, a cross would be reared. Possibly, hundreds of years might then elapse ere a church was built, but when it was, it would probably be raised upon that part of the stow where the primitive folk had been accustomed to bury their dead, and close by the venerable emblem of Christianity which had for so long marked the site of public ground. The very word "cross" is not, I believe, of English origin, but comes from the Cornish, Welsh, or Irish! A comprehensive view of a typical Cornish cross occurred in the *Illustrated London News* recently (Nov. 19th). Therein an evening scene in St. Lewan churchyard, near unto the Land's End, is cleverly drawn. Upon a crude, granite stile, some happy rustic lovers sit, whilst a tottering old grandpa, feebly feels his way towards the tomb. Just above the bankside, a genuine Tan cross rears its venerable grey head, and gives immense individuality to the scene. It may be pleasant to record here that the finest cross in all Cornwall has just been unearthed and re-erected by the Rev. W. Willmott, at Quethiock. It seems that, a few months ago, whilst some workmen were engaged in excavating in the southern part of Quethiock churchyard, they came upon the head and base of a handsome old granite cross. Further attention having been directed to some gate-posts, it was found that these actually formed the missing shaft, which had been hammered into two and utilised. The four pieces put together fitted exactly, and formed a perfect four-holed Greek cross. These have been all put up again upon the spot where tradition says the cross formerly stood, i.e., just south of, and about 20 yards from, the church. Its base is circular, and is 4 ft. 6 in. in diam. The head is pierced with four Trefods, symbolical of the Trinity, even as the inclosing ring represents Eternity. The head is 2 ft. 6 in. in diam. The shaft was a monolith, between 10 ft. and 11 ft. high, and beaded at each angle. The entire height of the Quethiock cross is 14 ft., several feet higher than any other in Cornwall. It is not an uncommon thing for the shafts of ancient crosses to be converted into gate-posts. Last year I was commissioned to restore the old cross at Honiton's Clist. "But," said the gentleman interested, "the stem is now doing duty as a post at a farm some miles away, and several times when it has been removed, the story goes that the Devil has fetched it back in the night!" I have some gratification in recording that I have put that old cross up again in such a way that no "devil" will ever be able to shift it anymore in a night, work at it as hard as he will! As a set-off to the happy recovery of the Quethiock cross, I am sorry to say that an old Latin cross which stood outside the south door of St. Kew Church, disappeared three years ago when the building was restored. This cross was certainly there in 1878; it is not there now. It has been whispered that it was actually broken up and used in the rebuilding of the church, but

such a piece of vandalism hardly seems creditable. This, however, I can testify to, and that is that the vicar of St. Keyne actually advertised his church's beautiful old carved oak crosses for sale in the Plymouth newspapers. By a most fortunate chance, the advertisement was seen by Mr. James Peters St. Aubyn, the well-known architect. To save them to the county, Mr. St. Aubyn generously bought the lot, and placed them in the south aisle of St. Ewe Church, where they now are. St. Ewe contains the finest oak-rood-screen in Cornwall. It is grained on both sides, is 15th-century work, and not unlike those of Somerset and Devon. I had the satisfaction of restoring it recently under Mr. St. Aubyn's careful superintendence. The removal of antiquities from one church to another is often open to grave objection. In Bodmin Church, for instance, a number of the roof bosses bear the arms of the families by whom the roof was given. If those bosses were translated to another church they would provokingly falsify the records. Every reader who visits Cornwall should go to St. Keyne, if only to drink at the celebrated well there, for:—

"If the husband of this gifted well,
Shall drink before his wife,
A happy man henceforth is he,
For he shall be master for life
But if the wife should drink of it first,
God help the husband then!"

—HARRY HEMS.

[6742].—**Compressibility of Air in Sewers.**—**MISPRINT.**—The word *above* on the ninth line from bottom should be *half*.—HUGH McLAUGHLIN.

[6760].—**Sp. G. and Crushing Weight of Stones.**—In my opinion Mr. Trickett would have shown himself less of a partisan if he had answered the whole question asked, instead of only on that stone in which he is more immediately interested. On the authority of Prof. Hull, the sp. g. of Red Mansfield stone in dry masses is 2.338, and in particles 2.753; its crushing weight is 5.12 lb. per sq. inch, or between 325 and 329 tons per sq. foot. The Dumfries stone referred to by "Veritas" is probably the same as the Corschill, and a few years ago I heard of the same stone used in the same buildings under both names. The strength of both the Corschill and Red Mansfield stones bears a crushing weight, as compared with the Bath and Portland stones, is very great, the ratio of the four being as follows:—Bath 1, Portland 1.42, Red Mansfield 3.42 and Corschill 5.31, taking the last at the mean of the three cubes supplied by Mr. Trickett. One important point in stones is the expense of working them, and I believe it will generally be found that this increases with the strength and hardness of the stones, perhaps in not so great a proportion, and exceptions will be found to such a rule owing to the unevenness of grain, veins, &c. I also think that comparing the Corschill and Red Mansfield stones, it will be found that the latter is the most even-grained stone and would be the most durable; the former has veins in part like grain in timber, which while adding to the beauty of the stone, I fear takes from its strength; this is to be seen to a much larger extent in some of the red sandstone in Germany; much of the stone at the Archbishop's Palace at Mainz appears to be of petrified timber.—HUGH McLAUGHLIN.

[6761].—**Baths.**—A discussion with much information on the subject of bath, their fittings, and mode of heating took place in the *Building News*, 1873, it commenced by an article dated Jan. 3rd of that year, it was followed by letters and another article in the following numbers, Jan. 10, 24, 31, Feb. 11, 21, 28, and April 18, the last of no so much importance. The size of cisterns necessarily depends on the supply required for house, and how often in each day the bath may be used or filled, also is the hot-water cistern required to supply house as well as baths? Fifteen gals. per day is allowed, or domestic pump sees for each adult and child, and by Metcalf's Pocket-Book 35 gals. for each time of using a bath. Having measured the bath in the house in which I dwell, I consider this insufficient, and make it 51 gals., and, according to one account, I find a bath when full holds 100 gals., this would appear correct. In the house in which I dwell, the hot-water cistern supplies bath, housemaid's sink and scullery and would hold about 42 gals., it is heated from a boiler at back of kitchen, and is filled by a small lead cistern from main cistern above, it being situated a little below the main cistern, the hot and cold water pipes run along side, this danger from frost is avoided. There is, of course, a separate cistern for drinking-water at the bottom of the house, and, since the house has been built, about twelve years, the cisterns and supply pipes therefrom have never frozen. The bath is fitted with 1 1/2 in. hot and cold service pipes, 1 in. waste and overflow pipes, the hot opening into lead safe below bath, and from thence, by a warming pipe into the courtyard, about 25 ft. below. The hot water inlet has 1 in. flow off or waste pipe conducted into the housemaid's sink beneath it.—HUGH McLAUGHLIN.

[6766].—**Heating Chapel.**—In my opinion, the best and cheapest method for the purpose named is "hot-air." A. B. M. might ask for estimates from Messrs. Grundy, Constantine, and Boyd, or other respectable manufacturers, he may remember that the cheapest of any method is not always the best.—H. McLAUGHLIN.

[6767].—**Fixing Weather Tiling.**—One way, and the simplest that is carried out, is to nail or peg the tiles to the mortar joints between the brick courses; this may be further improved by nailing the tiles to the brickwork in cement, which, I believe, has also been done without any fastening to the courses by nailing. Possibly the best method is first to battan the wall, and then secure the tiles to the battening in the usual manner.—H. McLAUGHLIN.

[6767].—**Breaking Weight of Girder.**—I wish to correct an error of the engraver, who, in reproducing the sketch, which compares the lifting power of my contribution to this work, *Building News*, has had to do with diagonal lines to the floor plate and angle-iron of girder. This did not appear in my original drawing. All that was crossed there were the lower angle-iron, floor plate, and two lower of the web, following the conditions of the formula given. I only wished to show, as stated in my reply, that the portion of the section that had been crossed over, the portion of the bottom flange.—ALFRED C. HUBLEY.

[6787].—**Breaking Weight of Girder.**—I notice in your "ante communication" column of last week an issue two answers to a query, which appear very excessive for a girder of that construction. According to the working out of Moleworth's formula, I find the breaking weight is 23 1/2 tons.—D. H. ROBINSON.

[6794].—**Problem.**—B. pays A. 4-14 of £1,050 (the cash paid in advance), equal £380, and A. returns to B. 10-11 of £200 (the excess of rent beyond the £250 per annum), equal £142 17s. 2d., so that A's balance is £157 2s. 10d., which, so far, agrees with the answer of "W. U. O.," but I do not consider this equitable if B is to pay a proportionate price, and for this reason:—A. pays down the whole £1,050 ten years before B. has any interest in the property, and this sum of £157 2s. 10d. has been all the time useless to A. (otherwise B. wouldn't give it back) whilst instrumental in securing some benefit which B. will enjoy—as evidenced by augmented rent, pointing to increased value—and which A. loses, though both pay in striking the above balance an identical rate. A., in fact, ought to receive, in addition to £157 2s. 10d., compound interest thereon for ten years at 4 per cent. per annum, which would amount to £75 9s. 4d., making the total sum due to A. from B., £232 12s. 2d.—W. J. CHRISTY.

[6794].—**Problem.**—Mr. S. Daws writes we are all wrong. I differ from him, and call his attention to the following figures:—The rent during the lease would be £3,700, which, divided by 250 = 14'8. A. having the lease 10 years would be liable for 10 parts, B. for 4'8. We have only to deal with the following amounts (see issue of Dec. 21):—1818-255, 509-959, and the extra of £50 per annum for four years = 212-32.

	1818-255	
Add together	509-959	
Divide by 14'8	2328-244 = 157'4	
157'4 x 4'8 B's share =	755-52	
Then 212-32 x 14'8 =	143-346	
A's share being 10 parts, B. is entitled to	143-346	
	612-66	

Within a few decimals of mine of 2nd inst.—G. B. L.

[6797].—**Villa.**—Replying to "Young Architect," I am afraid any answers he may receive will only mislead him on his questions, as it is almost impossible for one not knowing the site and conditions to answer. I can, therefore, only give general replies. 1. Prospect ought certainly to have something to do with the floor on which the drawing-room is placed, and if other things do not interfere the rule of placing it on the ground-floor may be waived in this case. 2. This question depends entirely on the habits of the occupant. If he is fond of social gatherings a service door would be very necessary; generally in small villas one door is made to answer. 3. This question also depends largely on the same consideration. A lavatory and w.c. attached would be necessary in every well-planned villa, and the ground floor is the right place for it. 4. Consult Wright's "Hints to Young Architects."—G. H. G.

[6799].—**Contracts.**—Had the contractor been allowed to erect the stone fence as originally intended, it is only fair to suppose he would have made a profit upon it. Seeing that the architect sent his account for iron-work to the contractor for payment, it is only right that he should charge some profit for lying out of his money, and the trouble he had in the matter.—E. CALVERT.

[6800].—**Liability of Builders.**—When the architect first discovered a fault in the wall he should have written the builder at once upon the subject. It is too late to find fault six months after the building is completed. I had a parallel case in regard to a retaining wall, which bulged as soon as it was built. I noticed it at the time, and spoke to the contractor's foreman on the subject, but did not write about it to the contractor. This wall ultimately fell, and the combined action of frost and rain causing a lateral pressure on the wall got the blame of it. Some unforeseen agency may have been at work to cause the fall of your wall. I can scarcely conceive that it was not built plumb.—E. CALVERT.

[6801].—**Professional Practice.**—If your client wishes a copy of the sad documents, why not let him have them? Everyone likes to see what they are paying for, although they may not altogether understand the account. You can do less harm in yielding than refusing.—E. CALVERT.

[6803].—**Hoop-Iron Bond.**—This should not be carried through opening.—T. R. H.

[6803].—**Hoop-Iron Bond.**—Some architects prefer the band carried through the openings and afterwards cut, but to this there is a great objection—viz., the eventual rusting of the iron and discolouration of the brickwork.—LEWIS.

[6805].—**Bath.**—If "Alba" would write "Eureka," 52, Queen Victoria-street, he would possibly get the information required. The information is too lengthy to insert in this paper.—E. ALBA CONCRETE.

[6805].—**Bath.**—One scarcely sees how the cement can be permanently whitened. Paint would never stand; but I know of cases where baths are annually lime-whited.—LEWIS.

[6808].—**Brick Arcade Arches.**—As a practical man, I would strongly advise your correspondent to have centres for each of his arches, and not strike them until absolutely necessary—that is, if he wishes or expects his work to stand.—LEWIS.

[6808].—**Brick Arcade Arches.**—It does not require the advice of an "able contributor" to reply to "One in Doubt," or I should not attempt it. A centre must be made for every arch in the arcade, and should be left in as long as possible, due attention being paid to their being properly eased as the weight gets on them, but do not strike them until it is absolutely necessary.—B. S. J.

[6809].—**Repairs.**—It appears that A., under the will, becomes, as it were, trustee for the property to B. He is, therefore, bound at his death to deliver up the said property, unless any agreement to the contrary in the same state and condition as it was in when he received it; hence A. should also insure.—LEWIS.

[6810].—**Ownership of Drawings.**—Unless there is some special agreement, the builder is not compelled

to deliver up to the architect the drawings with which he has been furnished to carry out the works. It would be rather amusing to see their state and condition after knocking about on a job, as it is not every builder who sends out tracings on to the works and keeps the drawings in his office. If the architect wishes to try the question he must enter an action against the builder for unlawful detention, and I would advise the latter to try it out.—LEWIS.

[6810].—**Ownership of Drawings.**—In my query the word "favourites" is printed in the fourth line instead of "furnishes." I think the error is the printer's, as I do not think it any favour to the builder.—C. B.

[6811].—**Force of Impact.**—In Spence's "Dictionary of Engineering," under the article "Pile Driver," will be found the required information. The force of the blow amounts to the weight of the falling body, multiplied by its velocity, at the instant of striking the obstacle. In this case the velocity is that acquired from falling through a space of 7 in. = 7-12 ft., and is found from the equation

$$V = 32 \cdot 1 \cdot 6 \sqrt{\frac{S}{g}}$$

where $g = 16 \cdot 1 \cdot 12$ and $S = 7 \cdot 12$. Substituting these values

$$V = 32 \cdot 1 \cdot 6 \sqrt{\frac{7}{193}} = 32 \cdot 1 \cdot 6 \sqrt{0.0362694} \\ = 32 \cdot 1 \cdot 6 \times 0.1904 \\ = 6.125$$

so that the force of the blow = 3×6.125

$$= 18'375 \text{ cwt.} \\ = 1 \text{ cwt. } 42 \text{ lb.}$$

—W. J. CHRISTY.

[6812].—**Ventilating Pipes.**—If "Architectus" procures a copy of the by-laws of the district, he will find therein the rules which relate to the ventilation of drains, &c., and with them he must comply.—LEWIS.

[6812].—**Ventilating Pipes.**—"Architectus" does not give size and position of his one ventilating pipe, nor sufficient detail to enable one to judge the case properly. The siphon he has inserted between house and sewer is not effectual without ventilation. By "the surveyor," I presume he means the surveyor of the local authority, and if the model by-laws of the Local Government Board, or by-laws similar thereto, are in force within the district, then "Architectus" has not complied with the provisions of such by-laws as to ventilation of drainage, which, described shortly, are as follows:—Trap in drain between house and sewer and as near sewer as practicable. (a.) One untrapped opening (not less than 4 in.) from surface of ground, as near as can be to the trap, down to the drain, and on house side of trap. A second untrapped opening at highest part of drains, carried up by pipe (not less than 4 in.) clear of openings into house, and in no case less than 10 ft. in height. Where the foregoing are impracticable, the following shall be substituted:—(b.) Carry up pipe (not less than 4 in.) between house and trap to a height of not less than 10 ft. The second opening to be at highest part of drains, and to be level with ground surface. All soil pipes to be fixed outside and carried up (clear of openings into house) full size, which in no case is to be less than 4 in. in diameter. Where the situation, sectional area, height, and mode of construction of the upward continuation of soil pipe shall be in accordance with the requirements as to ventilating pipes, such soil-pipe may be deemed to provide the necessary opening for ventilation, or, in other words, to answer in lieu of such pipe mentioned in (a) and (b). "Architectus" should obtain a copy of the by-laws referred to.—C. E.

[6813].—**Water.**—Various methods of keeping the water back have been tried, but they are uncertain, costly, and generally useless. Drain, if possible.—T. R. H.

[6813].—**Water.**—Take up the paving and put in about 4 in. of good cement concrete, and then plaster over this and up the sides 1 in. thick in cement to above where water comes in. If properly done the remedy will be effectual. Asphalt would also do, but the expense is much greater.—LEWIS.

[6815].—**Hospital Construction.**—In reply to "Sigma," pilot stoves or jets of gas are desirable in most cases where central stoves are used in hospital wards. But the horizontal flues in Mr. H. Saxon Snell's thermohydric grates are encased in sand, and are so constructed otherwise that piloting is unnecessary. Full details of these grates, and the manner of constructing the flues are given in Mr. H. Saxon Snell's "Charitable and Parochial Establishments," but the makers, Messrs. Potter and Sons, Oxford-street, would, no doubt, furnish any applicant with full details.—C. M.

[6815].—**Hospital Construction.**—At the London Temperance Hotel, Hampstead-road, in a number of Manchester stoves (Shorland's) all having draught smoke-flues passing under the floors from centre of ward. The draughts have all been very good, and no "pilot stoves" are required.—FRED R. BARKER.

[6816].—**Cracked Pipes.**—I have known the best quality pipe crushed by the pressure of earth in deep trenches, and should advise that in such work, or when so near the surface as to be liable to damage from a heavy roller, they be encased in 6 in. or 12 in. of fine concrete.—T. R. H.

[6817].—**Whitewash.**—If there be no other reason than that the ivy should grow on the wall, the whitewash could be scraped and swept off.—LEWIS.

[6820].—**Demurrage.**—The arbitration clause in contract clearly refers to the architect being sole arbitrator for extras only, and not for any differences or disputes. I think, however, he would be secure in giving certificate for contract and extras with the contractors mentioned. It is, however, always difficult to give a correct opinion unless one is thoroughly conversant with the whole case.—LEWIS.

[6820].—**Demurrage.**—The architect has discretionary power with regard to damages as much as in any other part of the contract. The clause as to time is useful and necessary; but, for all that, the enforcement of the fine would often be unjust and harsh. Sometimes the period for completion is absurdly short. The architect must consider weather, extra works, and alterations.—T. R. H.

LEGAL INTELLIGENCE.

METROPOLITAN BOARD OF WORKS V. STEED.—High Court of Justice: Queen's Bench Division. (Sittings in Bane, before Mr. Justice Grove and Mr. Justice Lopes.)—This was a case which was argued last week, when the Court took time to consider its judgment. It appeared that the respondent had been summoned before a police magistrate for infringing a section of the Metropolis Local Management Act, which requires that no road shall be formed as a street for carriage traffic unless such road be widened to the full width of 40ft., or unless such street shall be open at both ends. The road in respect of which the respondent was summoned was 400ft. long, leading out of the Holloway-road. It was 40ft. wide, but at the extreme end from Holloway-road it abutted on another man's land, where a bar was put up prohibiting further traffic, so that the road, in effect, was a *cul de sac*, and was not open at both ends. The magistrates, however, held that, the road being of the statutory width, no offence had been committed under the statute, whereupon the Board of Works appealed, when Mr. Poland appeared for the respondent, and Mr. Biron for the Board of Works. Mr. Justice Groves: In this case, at the conclusion of the arguments, we were inclined to think that the case should be re-argued before three judges, as we were not entirely of the same mind. Now, however, we take the same view, and, therefore, we proceed to give judgment. This is a special case framed by a magistrate, and the main question is as to the meaning to be attributed to section 98 of the Metropolis Local Management Act, and to one single word in that section, and that is the meaning of the word "or"—whether it is disjunctive or conjunctive. To my mind the word "or" means "nor," and is disjunctive. His lordship here read the section, and continued: It would certainly have been better and more grammatical, if the sense I give to the word "or" is right, had the word been printed "nor" instead of "or." The real sense is that the road must be of the specified width, and be open at both ends. This is, I think, the meaning of the statute, and the reading of the magistrate was, to say the least, far-fetched. A very long and narrow street would hardly be any better or more salubrious with both ends open than if one end was closed. The street might be a quarter of a mile long, and the open end would be of no practical value. I do not think we are doing in this case what we have often refused to do in other cases—viz., construing the Act against the plain meaning of its words. Here, where the word "or" applies to the two prohibitions, the word "or," when preceded by a negative sentence, has a different meaning to what it has when preceded by an affirmative one. I have not looked specially, or else I could find instances in Acts of Parliament and in well-known writers where the word does bear these meanings. For instance, suppose I say you must have your house drained or ventilated, there the word "or" is plainly alternative, and you will satisfy the conditions if the house is either drained or ventilated; but if I say you must not have your house undrained or unventilated, that clearly means that you must have your house neither undrained nor unventilated. Here, in this statute, there is a preceding negative sentence, and, according to the example I have given, the word "or" is disjunctive, and must be read as "nor." In my opinion, therefore, the appeal must be allowed. Mr. Justice Lopes delivered judgment to the same effect.

THE WREXHAM TOWN COUNCIL AND THE LESSEE OF THE SEWAGE FARM.—On Wednesday week the disputes which have arisen between Lieut.-Col. Jones, V.C., the lessee of the Hafod-y-wern Farm, and the Corporation, as to the carrying out of the contract as originally agreed upon, came on for arbitration before Mr. Clare Sewell Read, acting for Lieut.-Col. Jones, and Mr. Evan Morris, solicitor, Wrexham, representing the Council. The arbitrators are also to decide the amount of damages (if any), to be paid to Lieut.-Col. Jones for the breaches of the covenant complained of. Mr. C. W. Cresswell, instructed by Mr. Vaughan Williams, solicitor, Wrexham, appeared for Lieut.-Col. Jones, and Mr. Higgins, instructed by the Town Clerk of Wrexham, for the Corporation. The inquiry was adjourned, after some evidence had been heard, to a date to be subsequently agreed upon.

ANOTHER CLAIM FOR EXTRAORDINARY TRAFFIC.—On Tuesday week, at the Apsinston Police-court, the case of The Seaton Local Board v. The Beer Freestone Company was heard. Mr. George Tweed, of Honiton (instructed by Mr. E. H. Wilton, solicitor, Colyton, and Clerk to the Seaton Local Board), appeared for the local board; and Mr. Arthur Ward, of Exeter, represented the defendants. In opening the case, Mr. Tweed said that he should ask the bench for an order that the defendants should pay the sum of £32 5s., on the ground that they had incurred that sum owing to their causing extraordinary traffic and excessive

weight to pass over the Beer-road from a point called Beer-hill to the Seaton Railway Station. The proceedings were taken under the 23rd section of the Highways Act, 1878. After a short consultation, the Chairman said that the Bench had no hesitation in coming to the conclusion that there had been extraordinary traffic and excessive weight, but taking into account the fact that the Company only began to work the quarries in the month of July, 1880, the Bench considered that three-quarters of the claim would be an adequate amount, and, therefore, they would make an order for £24—the costs to follow judgment. Mr. Ward intimated that he should give the necessary notice of appeal in this case.

WATER SUPPLY AND SANITARY MATTERS.

KILCREGGAN AND COVE WATER SUPPLY.—The first sod of the works for providing pure water to the sea-side resorts of Kilcreggan and Cove, N.B., was publicly turned on the 26th ult. The scheme has been prepared and is being superintended by Mr. Brand, C.E., of the firm of Messrs. Wharrie, Colledge, and Brand, civil engineers, Bath-street, Glasgow. The water is brought from the loch at Lochan-Ghlas-Laoigh, on the hill above Coulpport; this has a surface area of 20 acres, and lies 510ft. above the sea-level, and the water has been pronounced by the city analyst of Glasgow as of the same quality as Loch Katrine water, except that it contains more vegetable matter. A supply of 42,000,000 gallons is proposed to be taken, equal to 503 days' supply at 40 gallons per head, and the water will be conveyed in 12in. pipes to Duclage farm, where, after filtration, it will be stored in a tank holding 165,000 gallons, and afterwards will flow by gravitation to the villages to be supplied. The length of pipes is 13 miles. Mr. Peter Quin has taken the contract for laying the pipes and erection of filters; Messrs. D. Y. Stewart and Co. have that for the supply of pipes; and Messrs. Allen and McLellan that for the valves, &c.

THE FORFAR SEWAGE-FARM.—Mr. Campbell, the officer of the board of supervision, in a report to the board under the Public Health Act, says of the Forfar sewage-farm:—The Rivers Pollution Act, wherever enforced, has closed against local authorities the former easy mode of disposing of sewage by passing it on with all its impurities to the nearest stream. How to separate, in the volume of liquid poured through the sewers, the foul matter carried off by the water from the water itself, is a problem which the local authorities of inland towns and villages are now bound to solve. The water must be restored, as far as possible, to its original state of purity before it is allowed to enter stream or river. I found the solution of this problem exhibited in the sewage-farm of Forfar. I saw the foul, dark liquid passed over the farm, and on examining the effluent outlet, the water was seen pouring from it in appearance pure, as from a fountain spring. The system adopted at Forfar is that of intermittent downward filtration, combined with surface irrigation, which was carried out by Messrs. Bailey Denton, Son, and North, the engineers, of Whitehall-place, London.

ROSS.—At the last meeting of the Ross Town Commissioners, it was resolved, "That the scheme of Messrs. Gatto and Beesley for supplying the town of Ross with water from the River Wye, taken from above the rocks, and pumping it up to the high ground near Springfield and filtering it, be adopted; and that the clerk be instructed to apply to the Local Government Board for sanction to a loan of £7,000, to be raised by the commissioners to carry out the works."

RHONDDA VALLEY SEWERAGE SCHEME.—Mr. Lomax, C.E., the engineer appointed to carry out the sewerage of the Rhondda Valley, on Thursday week explained to the members of the Ystrad-fodwg local board his scheme. It is divided into two portions, No. 1 dealing with Trehafod, Porth, Cymmer, Ynshyr, Paridy, Penygraig Tongpandy, Llywynnyn, and a portion of Pontrhondla. For this district, having a population of 24,000, the engineer proposed to lay a main intercepting sewer along the bed of the Rhondda, an alternative scheme proposing to carry the intercepting sewer along vacant land adjoining the river in certain places. No. 2 district deals with the remaining hamlets and villages with a separate sewer, and the collected sewage is to be precipitated and filtered through earth, the effluent passing into the Rhondda. The scheme will be carried out, if finally approved, under the supervision of Mr. W. Jones, surveyor to the local board.

The local board of Claines, near Worcester, last week instructed Mr. Purchas, C.E., to inspect the district, and to report on the best way of disposing of the surface-water and slops.

Our Office Table.

THE terrible disaster at Vienna teaches no new lesson: it only adds to the bitter experience already accumulated of the results of neglecting old ones. We have only very narrowly missed such a calamity in this country on more than one occasion—in 1865, for instance, when the Surrey Theatre was burnt down in so short a space of time that, had it occurred at night instead of during the day, when the theatre was of course empty, very few of the many hundreds who would have been inside could have escaped with their lives. Fires at theatres are fast becoming more fatal than battlefields, yet no theatre as yet has been responsible for loss of life so great as that which occurred in 1863 at the church of La Campana at Santiago, when, in one hour, 2,000 people were reduced to ashes, so that the comparison of the construction of theatres with that of churches, made by some well-meaning advisers, does not go for much. What is wanted is the more thorough enforcement of well-devised regulations, both as regards theatre construction and appliances, and the rigorous punishment of any theatre proprietor who causes death by his neglect of their observance. Meanwhile—especially during the approaching pantomimes, with their flaring transformation scenes—every father of a family had better carefully note the peculiarities of the passages by means of which he obtains entrance, and mentally calculate his chances of exit, with a child or two on each arm, through a maddened and terror-stricken mob.

A LARGE and influential meeting was held in the Chapter House at Westminster on Tuesday, in furtherance of a scheme for raising a memorial to the late Dean Stanley. The Dean of Westminster presided, and among the speakers were the Prince of Wales, Earl Granville, the Archbishop of Canterbury, Lord Salisbury, Lord Lorne, and Mr. J. Russell Lowell. It was resolved to raise a national memorial to the late Dean, to take the form of a recumbent figure in marble, to be placed in the Abbey, and the completion of the windows in the Chapter House, in accordance with the plan commenced by himself.

The following memorial, signed by Sir Henry Cole, Mr. William Morris, Mr. H. S. Milman, director of the Society of Antiquaries; Mr. J. L. Pearson, R.A., architect of Westminster Abbey; Mr. F. C. Penrose, and others, has been presented to the Governors of Westminster School by the Dean of Westminster.—"On behalf of a meeting of gentlemen interested in the preservation of Ashburnham House and of the ancient remains on its site, and earnestly desirous that no encroachment should be made on the ground closely adjacent to the Abbey Church of Westminster, we venture to request that the governing body of Westminster School will not come to any decision adverse to the proposal about to be made by the Dean and Chapter until they have received and heard a deputation from such meeting on the subject."

THE Fifteenth Annual Convention of the American Institute of Architects closed on November 17, after a very agreeable and harmonious meeting. The convention, according to the *American Architect*, seems to have been quite as well attended as usual, and although no important questions were decided or even discussed, the field was at least left in a favourable condition for such as may come up in future. On the whole, the past year has been a prosperous one for the Institute. The individual chapters have not perhaps gained so much as was anticipated from the relaxing of the bonds which connected them with the national body; but the same step has had the effect of removing the Institute, as it were, to a somewhat higher and less familiar sphere, increasing the dignity of the organisation, and perhaps so far furthering the objects to which it was intended to apply itself. The opening address, by Mr. Latrobe, of Baltimore, was of itself enough to make the present convention memorable.

THE twenty-seventh annual general meeting of the members of the Society of Engineers was held on Monday evening last, the 12th inst., in the Society's Hall, Victoria-street, Westminster. The chair was occupied by Mr. Jabez Church, vice-president. The following gentlemen were balloted for and duly elected as the council and

officers for the ensuing year, viz.:—As president, Mr. Jabez Church; as vice-presidents, Mr. F. E. Duckham, Mr. Arthur Rigg, and Mr. W. Schouheyder; as ordinary members of council, Mr. R. Berridge, Mr. S. Cutler, Mr. C. Gandon, Mr. C. J. Light, Mr. Perry F. Nursey, Mr. Heber Duckham, Mr. A. F. Phillips, and Mr. Arthur T. Wainisley—the three last-named gentlemen being new members of the council; as honorary secretary and treasurer, Mr. Alfred Williams; and as auditor, Mr. W. H. Bennett. The proceedings terminated by a general vote of thanks to the council and officers of 1881, which was duly acknowledged by the chairman.

BLAST-FURNACE Slag and its Uses was the subject of a paper read on Saturday evening, at the Middlesbrough Oddfellows' Hall, by Mr. Charles Wood, of the Tees Ironworks. Slag (said the lecturer) was now being turned into various commercial products, whereas for many years it was only used for road-making. Perhaps the largest utiliser of slag was Mr. J. Fowler, whose vast undertaking at the Tees breakwater showed marvellous enterprise, in which some half a million tons of slag were annually used. Mr. Wood showed the process of procuring the slag for the South Gare breakwater, saying that the latter was so far completed, after several years' workmanship, that on Saturday orders were received to cease sending slag there, and the contractors were preparing to send it instead to the North Gare breakwater. Another stage in the utilisation of slag was to run the liquid slag direct from the furnace into a mould. Casts had been so made that were beautiful to look at; many attempts had been made to bring that product into marketable use, but eventually abandoned. Slag paving-blocks, Wood's slag shingling machine, slag sand, concrete, and slag wool were next referred to, the process of making each and the texture of each being minutely explained. It was stated that of the concrete bricks about 130,000 tons per week were making, consuming about 20,000 tons of slag per annum.

In consequence of the distribution of the Royal Academy prizes taking place on Saturday night, the students decided to give their supper on Monday, the 12th. The supper was given at Willis's rooms, Mr. Wilton Grossmith being in the chair, and supported by the president, Sir Frederick Leighton, Messrs. F. R. Pickersgill, R.A., Alma Tadema, R.A., J. C. Horsley, R.A., E. Armitage, R.A., W. C. Dobson, R.A., J. E. Hodgson, R.A., G. D. Leslie, R.A., W. Calder Marshall, R.A., H. T. Wells, R.A., Edwin Long, R.A., W. W. Ouless, R.A., E. B. Bird, A.R.A., F. Dicksee, A.R.A., S. L. Fildes, A.R.A., Frank Holl, A.R.A., P. R. Morris, A.R.A., Val Prinsep, A.R.A., Marcus Stone, A.R.A., Prof. Marshall, Mr. R. Phené Spiers, Mr. Ballantyne, and others. There were about 300 present altogether, being the largest entertainment of the sort ever given. The speakers were few in number. Captain Ballantyne, R.N., responded for the "Army, Navy, and Volunteers"; Sir Frederick Leighton, P.R.A., for "the members and professors of the Royal Academy"; and Messrs. Fisher, Hook, Juce, Junck, and Paret for the prizetakers, proposed by Mr. J. C. Horsley, R.A. The entertainment was of a most brilliant character, including recitations by Sir William Magnay, Bart., and Mr. H. Beerboom Tree; songs by Mr. G. L. Calkin and Mr. Arthur Mathison, songs and recitations by Mr. Terry, the actor; and songs, recitations, and musical sketches by Mr. George Grossmith; the company not separating till after 2 a.m.

The third of the series of Cantor lectures by Mr. Thomas Bolas, F.C.S. (on "The Industrial uses of the Calcium Compounds") was delivered on Monday, December 5th. After treating with sulphate of lime and its occurrence in nature, the lecturer mentioned the various qualities and species of gypsum, and alabaster, and proceeded to describe plaster of Paris, its preparation, and uses. The fire-proof concrete of Messrs. Dennett and Ingle, prepared from highly calcined gypsum, was shown and favourably commented upon. The lecturer also passed round a sample of "Super-super" plaster manufactured by Messrs. Bellman and Ivey, of 95, Wigmore-street, W., and called attention to its extremely fine character. The application of plaster of Paris, in the form of a stucco marble, as manufactured by the same firm, was explained, and the specimens shown (in which the material was applied to columns,

pilasters, wall-linings and pedestals for statuary) were much admired on account of their high polish and admirable representation of the marbles.

THE First Norfolk Artillery Challenge trophy, intended for competition in repository drill, was modelled by Mr. G. Archard, from drawings prepared by Mr. H. Dudley Arnott, architect, of Great Yarmouth. The trophy represents a 61-pounder M.L.R. gun of 71wt., mounted on a temporary sleigh, built up of the stores used in the service in dismounting and shipping ordnance. The materials used in the model (excepting the gun, shells, and cordage, which are of solid silver) is the same as that in actual service, and, together with the guns, shells, cordage, and other portions of the trophy, modelled to a scale of lin. to the foot. The plateau upon which the gun and sleigh rest is supported by six cannon shells and festooned with parbuckle ropes. The base of wainscot oak, with ebony reliefs, bears upon its several sides silver shields containing the arms of the different towns which are the head-quarters of the various batteries, viz., Norwich, Beccles, Lowestoft, and Aldeburgh, the arms of the brigade head-quarters, Yarmouth, being richly enamelled, and in high relief.

WE regret to learn that Mr. George Childs has recently died at his residence, 21, Offord-road, Barnsbury, after a long and painful illness, leaving his wife and family in great difficulties and a daughter severely afflicted. Many of our readers must have had occasion to avail themselves of Mr. Childs' services, and we feel sure if any of them feel sufficiently interested in his misfortunes to assist in any way those he has left behind him, their kindness will be wisely and beneficially displayed.

CHIPS.

Mr. C. B. Birch, A.R.A., has been commissioned by the Liverpool Conservative Club to execute the statue of Lord Beaconsfield to be erected in front of St. George's Hall.

A handsomely-carved Caen-stone pulpit, with red Mansfield columns to base, in the Early English style of architecture, has recently been completed for St. Stephen's Church, Nottingham, by Messrs. Jones and Willis, of Birmingham and London. The body consists of gabled panels—gables supported by red serpentine marble columns—and with the subjects, in panels, of the Four Evangelists, with carved monogram to fill centre panel. The gables are finished above with diaper-work and green serpent ne marble.

A memorial stained-glass window has been placed in Shaw church, Berks, the subject being the miracle at Cana of Galilee. Mr. Alexander Gibbs, of Bloomsbury, carried out the work.

The Bromsgrove local board received a report from Mr. Parker, C.E., as to a sewerage scheme of outlying roads, estimated to cost £2,000.

The Poole town council have adopted plans by their borough surveyor, Mr. H. Miller, for proposed baths and washhouses, the estimated cost being £4,000.

"Barracks" for the Salvation Army have just been opened in Willow-street, Coley, near Reading. The building seats 1,000 persons, and is said to have cost £2,000. "Commissioner" Sherwood, of the Head-quarters, Whitechapel, acted as architect.

At a general assembly of the Royal Academy held last week, Mr. Peter Graham, painter, was elected a Royal Academician.

In our description last week of the new Sandford-street Board-schools at Swindon, on p. 758, the name of Mr. T. Elsley, Great Portland-street, the manufacturer of the window-fittings, was incorrectly given as "Elsey."

Unless some arrangement is made, the construction of another bridge over the Tay at Dundee may be abandoned. The 21st section of the New Tay Bridge Viaduct Act, passed last session, provides that the old structure must be abandoned and removed to the satisfaction of the Board of Trade before the new one is erected. Last Friday, Mr. Stirling, the chairman of the North British Railway, several of the directors, and the engineer, had a meeting with the Dundee Harbour trustees, to discuss this unforeseen impediment to the progress of the new undertaking.

Holloway's Ointment and Pills are never at fault in successfully disposing of skin diseases, eruptions, sores, and venereal affections. In all venereal diseases there is a tendency to be relied upon, and by their means the most delicate may become strong, and the foulest blood may be gradually changed into the purest fluid.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—London Institution, Finsbury-circus. "Colour as Applied to Architecture," by G. Aitchison, A.R.A., F.R.I.B.A., 5 p.m.
Surveyors' Institution, 8 p.m.
Royal Institute of British Architects. "The Artistic Treatment of Constructional Ironwork," by H. H. Stannus, A.R.I.B.A., 8 p.m.
TUESDAY.—Institution of Civil Engineers, Annual general meeting, 8 p.m.
THURSDAY.—London Institution. "Mark Twain," by Rev. H. R. Haweis, M.A., 7 p.m.
Edinburgh Architectural Association. Annual Dinner.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE FOURTH ORDINARY MEETING of the Institution will be held on MONDAY, the 19th instant, at 5 p.m., when a Paper by HUGH STANNUS, Associate on THE ARTISTIC TREATMENT OF CONSTRUCTIONAL IRONWORK, will be read.
J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.
9, Conduit street, Hanover-square London, W.

Epps's Cocoa.—Grateful and Comforting.—It is a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame. *—Civil Service Gazette.*—Made simply with boiling water or milk. Only in Packets labelled *—JAMES EPPS & CO., Homoeopathic Chemists, London.*—Makers of Epps's Chocolate Essence for afternoon use.

Lampough's Pyretic Saline is refreshing most agreeable, and the preventive and curative of FEVERS, RHEUMATISM, SMALLPOX, SKIN DISEASES, and many other ailments. Sold by chemists throughout the world, and the M-Ker, 113, Holborn Hill. *Use no substitute. See Medical Testimony.*

Douling Freestone and Ham Hill Stone

of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,

Norton-sub-Hamdon, Ilminster, Somerset.

—[Advt.]—

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates.

General Repairs and Alterations Executed.

Experienced Workmen always in readiness, and sent to any part of the country.—[Advt.]

BATH STONE. BOX GROUND, THE BEST FOR ALL EXTERNAL USE. CORSHAM DOWN

CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.

(See trade advt. on p. XXIII.) A377.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

BATTERSEA, S.W.—For the enlargement of Stamford-street School, Battersea Park road, by 400 places, for the London School Board:—

Boyce, T.	£7,940 0 0
Hobson, J. D.	7,624 0 0
Downs, W.	7,353 0 0
Shurair, W.	6,993 0 0
Atherton and Latta	6,970 0 0
Marsland, J.	6,885 0 0
Nightingale, B. E.	6,725 0 0
Higgs and Hill	6,784 0 0
Oldrey, W.	6,784 0 0
Lathey Bros., Battersea	6,462 0 0

[Cost per head of school buildings, £5 16s. 11d.; total cost per head, £16 11s. 4d.]

BERMONDSEY, S.E.—For alterations and extension of premises, The Grange, Bermondsey, for Messrs. S. Barrow and Brother, Messrs. E. Kingdon and Son, architects. Quantities by the architects:—

Buller	£475 0 0
Wells	353 0 0
Eldridge and Gee (accepted)	318 0 0

BETHNAL GREEN.—For the erection of a school for 1,100 children in Mansford-street, Be haul Green, for the London School Board:—

Higgs and Hill (accepted on revised plans), £13,550

Cost per head of school-buildings, £5 8s. 6d.; total cost per head, £9 13s. 8d.]

BLACKHEATH, S.E.—For constructing 110 ft. run of 15 in. sewer in Charlton-road, Blackheath, for the Greenwich district board of works:—

Pount, J., Lee (accepted)	£160 0 0
---------------------------	-----	-----	----------

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 23, 1881.

GEORGE EDMUND STREET, R.A.

DEATH has been very busy amongst us this year, and busiest among our best. Our Christmas Number, indeed, is in great part an obituary, and the losses we record elsewhere, dwarfed as they are in comparison with the great loss which overshadows the heart of every one to whom the name and reputation were dear of the man whose life and works best embodied this century's noblest traditions of English architecture, make up no mean contribution to the death roll of 1881. Some of these men, indeed, already belonged either to the past or to the future as far as our knowledge of them was concerned. To most of us, Decimus Burton and Anthony Salvin were familiar only by their works, and the others had hardly done more than give promise of the fair careers that seemed to await them, but the death of George Edmund Street re-awakens even more poignantly the emotions of regret and grief with which William Burges was laid to rest last spring. Both were without rivals in their own spheres, and only rivals themselves in the splendour and truthfulness of their work, and the double blank left by the loss of both in English architecture is, indeed, a dark one. The death of each of them, too, caused doubtless by the self-same devotion to their work, had also this in common, that none of us thought we were about to lose them. Not many days since we recorded with pleasure Mr. Street's partial convalescence—not without misgiving, as we remembered how we published the same statement with regard to Burges, and how that was succeeded the next week, just as now, by the news of his death. From the attack of paralysis with which he was seized a few weeks since, Mr. Street had, indeed, so far recovered his strength that he was enabled to leave the house, and was actually preparing to make a journey to Egypt for the benefit of his health, when he was again struck down with paralysis on Thursday week, and from this attack he never rallied, but expired last Sunday night at the comparatively early age of 57, at his house in Cavendish-place. It is almost needless to say that his death removes one of the most active and conscientious, as he was certainly the ablest, exponent of Gothic architecture and art of the present generation. His death, moreover, leaves a void in the ranks of the profession, not only in this country but on the Continent and in America. Mr. Street was as well known in Paris and in Rome as in England, and had won a distinguished reputation among architects and artists in the United States, and the expression of the esteem in which he was held by his foreign brethren was emphasised by many marks of personal regard.

Mr. Street was born at Woodford, in Essex, in 1824, where his father, Mr. Thomas Street, lived, who was the head of a firm of London solicitors. Receiving his education at the Collegiate School at Camberwell, in March, 1841, he commenced his professional education at Winchester, and became a pupil of Mr. Owen B. Carter, an architect of more than local reputation, and well known as a skilful draughtsman, with whom he remained three years. In April, 1844, Mr. Street entered the office of the late Sir G. Gilbert Scott, where he remained till 1849, when he went to Wantage and commenced practice for himself. At this place he formed an intimate friendship with the

rector, the Rev. D. Butler. In the year 1852, having been appointed diocesan architect, he went to live in Oxford, and in the same year married his first wife, Mariquita, the daughter of Robert Proctor, Esq., of Gey's House, near Maidenhead, the issue of which marriage is his only son, Mr. Arthur Edmund Street, who was born in 1855, and has been lately with his father, and has taken an active part in his business. The appointment to the office of diocesan architect was obtained through the friendship of the late Bishop Wilberforce, who quickly perceived the ability and earnestness of the young architect, who was, moreover, a staunch Churchman. Mr. Street came to London in 1856, and first began to practise at 33, Montague-place, after which he moved to 51, Russell-square, where he practised till 1870, in which year he removed to his last residence in Cavendish-place. Mr. Street, having been left a widower in 1874, on Jan. 7th, 1876, married Jessie Mary Anne, daughter of Mr. William Holland, who met with her fatal illness while on a visit to Rome, and died in London only two months after the marriage.

Mr. Street held the appointment of diocesan architect not only of Oxford but to the dioceses of York, Oxford, Winchester, and Salisbury. His comparatively short career has been one of almost unparalleled activity, only equalled indeed by that of his illustrious predecessor, Sir Gilbert Scott. He was a great traveller; his draughtsmanship was unrivalled, and the rapidity and accuracy with which he could sketch out working details for his numerous works on the spur of the moment, and without the aid of instruments, was remarkable. It is well known that something like 3,000 working drawings were prepared by his own hand for the new Courts of Justice, and that he had lately furnished details for this great work which had practically completed his labours in connection with that undertaking. He knew personally most of the celebrated buildings in Europe; few of them had not at one time or another been sketched by him, and he lost no opportunity of recording the results of his labours. He seemed never to tire of taking the front in any movement or controversy which promised to help the cause of art in any manner. It was, however, his work as a practical architect which has brought his name into world-wide repute. He erected dwellings in every county in England, in Scotland, and in Ireland, as well as in many European cities. His earliest work was in Cornwall—viz., at Biscovey, and other parts of the county, and at Hadley Church, in Essex (circa 1844). As an ecclesiastical architect he attained, after Sir Gilbert Scott, the foremost position and the widest practice ever held probably by one architect in any age or country. We can only name here a few of his most noteworthy new churches, appending below a more complete list. Among them are Kingstone Church, Dorset—built in marble for Lord Eldon; St. Mary Magdalene, Paddington; Toddington Church; St. Saviour's, Eastbourne; St. John's, Torquay; All Saints', Clifton; St. John the Divine, Kennington; St. James the Less, Garden-street; the Garrison Church, at Portsmouth; and St. Margaret's, Liverpool. Among the numerous restorations and additions to churches, we may name Christ Church and Synod Hall, Dublin; new nave and western towers of Bristol Cathedral; Kildare Cathedral, the south transept of York Minster; St. Luke's, Lower Norwood; St. Peter's Mancroft, Norwich—now in progress; St. Peter's, Bournemouth; Salisbury Cathedral; St. George's, Bloomsbury; Wellington Barrack Chapel—a wonderful transformation, as pointed out by Mr. Arthur W. Blomfield—as noteworthy examples of his

skill as a restorer. Of churches abroad, may be mentioned two in Rome—one for the English and one for the Americans; one in Paris, the Memorial Church in Constantinople, besides English churches at Genoa, Loussanne, Vesay, Murren, &c. A very unique series of about a dozen churches was designed by Mr. Street in Yorkshire for one client, Sir Tatton Sykes.

Among houses and other buildings we must particularly mention Dunecht House and chapel for Lord Crawford and Balcarres; St. Margaret's Convent, East Grinstead; Holmdale, near Dorking; Dundee House of Mercy; Haddo House, additions and chapels; Cuddesdon, Theological College, Longmead, Bishopstoke; school buildings at Uppingham, and at Marlborough; house in Cadogan-square, private chapels, Grwyth Castle, and at Luton Hoo. His last and greatest work, the Royal Courts of Justice (to which he was appointed architect in 1868), is the one on which his reputation will mainly rest, and it is some satisfaction to know that the building is practically complete; and that the drawings which Mr. Street has left behind him will enable every detail to be finished in its integrity. Mr. Street's reputation, as we have said, was as great abroad as at home, as the honours and distinctions won by him prove. One of the earlier competitions (1855-6) in which he engaged was that for the cathedral at Lille, in which he won the second premium, the first going to Messrs. W. Burges and H. Clutton. How the work and the premiated designs were ultimately handed over to a local competitor, who occupied a low place in the contest, we recounted in April last in our memoir of Mr. Burges.

We have not named one building in our list which deserves more than casual notice, as it stands quite distinct in its character and design. It is the beautiful little church erected at Holmbury, Surrey, at his own cost, and which was consecrated and presented to the parish in 1879, and near which Mr. Street had built his country house. "The Church," he remarked, in alluding to his gift, "has been so constant a friend to me, that a crowning desire of my life was to do something for it in return." He had, indeed, throughout his life been a consistent and earnest Churchman. For many years he was a member of the congregation, and, indeed, the churchwarden, of All Saints', Margaret-street, the valued and trusted friend of the late Mr. Richards, and of his successor, Mr. Berdmore Compton. He was also, up to the time of his death, on the council of the English Church Union. He was also, throughout his life, a devoted ecclesiastical student, and spent much of his time in the designing of metalwork and ecclesiastical furniture. In every instance which we have seen, he has shown, not only a thorough acquaintance with the styles he designed in, but the true spirit and feeling of the artist.

The distinctions which were awarded to Mr. Street were numerous. In 1859 he became Fellow of the Institute; in 1867 he was elected an Associate of the Royal Academy, and in 1871 became R.A., and also occupied the high post of Treasurer, in succession to Mr. Edward M. Barry. He was elected President of the Institute this year; he was also Fellow of the Society of Antiquaries; he was a member of the Imperial and Royal Academy of Fine Arts at Vienna, and a Knight of the Legion of Honour, besides a number of other societies. It is not probably out of the remembrance of our readers that, on the refusal of Mr. John Ruskin, on the very moment of the presentation, to receive the Royal Gold Medal of the Institute of British Architects, Mr. Street enabled the Council to escape the difficulty of their position by accepting

it. In 1878 a correspondence took place between Mr. Street and the Archbishop of Canterbury, as to his replacement, at the instance of Dr. Thomson, by Sir Edmund Beckett, as architect to the York Diocesan Society, and later, our readers know what an active part he took in the matter of the restoration of St. Alban's Abbey, as well as his strenuous exertions to save the west front of St. Mark's, Venice, from what he considered the destroying hand of the modern restorer, and called meetings, of which he was the chairman, at his house.

In matters of professional practice he was always ready to use his influence as a champion of right. In 1880 he presented the competitions memorial to the Institute Council, a document which has had some practical effect in bringing about recent reforms of the Institute. Few of our readers have forgotten his recent election as president to the Institute of British Architects. Whatever may have been urged by the supporters of the Council, there could have been but one opinion as to the pre-eminent fitness of Mr. Street for the post. As an exponent of the art side of architecture, he enlisted the attention and support of many of the leading architects, especially the younger members, and his recent utterances from the presidential chair at the opening of the session still ring in the ears of those who listened to him, and must have convinced even his opponents of his earnestness in the cause of art and professional reform. Turning from his active career as an architect, we may refer to Mr. Street's position as an exponent of architecture. As a lecturer, he was always worth listening to for his earnestness and vigorous advocacy of Gothic principles. Our own pages have, from time to time, teemed with the results of his consistent teaching. As long ago as 1859, he made an appeal on behalf of the study of the Mediæval architecture of Italy, which appeared in a letter in our pages, in reply to Mr. Parker, and delivered lectures on the same subject (*BUILDING NEWS*, January 7, 1859). In 1879 he delivered a lecture on his favourite phase of Gothic, the Early English, before the St. Paul's Ecclesiological Society, a paper marked by thorough knowledge of the details of this beautiful period, which was reported in full, and illustrated by diagrams, in the *BUILDING NEWS*. As lecturer on architecture at the Royal Academy, Mr. Street has had no equal of late years, and his election to the Chair of Architecture was a well-paid tribute to his ability. We need not here say much of the thoroughness, learning, and earnestness shown in the course of lectures he gave at the Academy, which were reported in full by us at the time. They were masterpieces of teaching, clear and incisive in style, and though they clearly expressed the author's preferences, they showed him to be an accomplished student of other great schools of art, and one who could sympathise with Classic as well as Gothic design. The preliminary lecture was especially excellent in its enunciation of sound principle, and the thoroughly good advice it gave to the student of architecture, and we may express a hope that the few lectures delivered by him will be published in due course.

Mr. Street was the author of several important works. The "Brick and Marble Architecture of North Italy, in the Middle Ages," 1855, was a work which followed Mr. Ruskin's celebrated book on the Stones of Venice, and was written when its author's impressions of Italian Gothic were strong and vivid, and the influence of the style may be seen in many of the earlier works of the author, as at St. James', Westminster. The book exercised a powerful influence over the Gothicists of the day, though it is well to remark that Mr. Street's taste under-

went a change in favour of a more Northern style. The "Brick and Marble Architecture" was followed by "Some Account of Gothic Architecture in Spain," 1865, another work evincing a keen feeling for and appreciation of the more florid types to be found in that country.

Mr. Street's position and character as an architect, and a due estimate of his work, may safely be left to the dispassionate judgment of posterity. He was always sincere in his views, and fearless in asserting them, and he will ever hold an unrivalled position as a Gothicist who caught up the Gothic spirit in its thoroughness and integrity. As a thorough Churchman he had a real sympathy with the style he practised, and seemed ever to display those capabilities which we are accustomed to associate with the Mediæval masters. No other great Gothicist of our own age, save perhaps Pugin, ever devoted so much time and thought in the preparation of his designs, and as we are told on the best authority, no architect who ever lived drew so much with his own hand as Mr. Street. It was this practice which has stamped on all his work so much individuality of character, and the personal interest in art the deceased artist never failed to inculcate in all his spoken and written utterances. The value of draughtsmanship, pure and simple by the hand and eye, unaided by instruments, was ever enjoined by him on all students. Mr. Street's inaugural address at the Institute was a strong protest against the flippant style and meretricious kinds of display aimed at by many architects. How strongly he insisted upon the necessities of plan and construction, few will forget who then heard him. There is one quality in all his executed works, and notably the New Law Courts, which may well be referred to, and that is the massive character of his work. Mr. Street was never tired of dwelling on the value of real durability in building as far above every other consideration, and the employment of ornament only when it could be well afforded. The New Palace of Justice has been the subject of many adverse critical remarks, and the question of the real authorship of the plan, which is its greatest merit, has been already again raised, not very gracefully we think, by an anonymous writer. We are, at any rate, glad to see that the architect most interested in this matter—one of the four architects who are all that remain out of the ten who took part in that ever memorable competition, has promptly recorded his testimony to the fact that "Mr. Street has stamped the impress of his own fertile imagination not only on his plan, but on every detail and feature of his work," and that "none can rob his memory of any of the honour due to his genius alone as the designer of the new Palace of Justice."

Like others of his professional brethren, who, it might be thought, could have little in common with the art instincts of its designer, Mr. Street had his scheme for the completion of our metropolitan cathedral. Our readers may remember that we have more than once expressed our conviction that his proposal to retain the choir as at present for ordinary services, and to erect a second altar of more magnificent proportions under the dome, always seemed to us the most sensible of the many suggestions made from time to time, and the realisation of his idea would, it seems to us, be no unfitting memorial of his name, if such should eventually be contemplated, in addition to those which he built far and wide for himself throughout his short but active life, and of which few knew the full extent, so absent was there any disposition in their author to talk about his own performances. One of his latest letters to us recalls the modesty with which he shunned anything like ostentation or flattery. After his acceptance

of the Chair of Architecture at the Royal Academy, we had begun, naturally enough, to speak and write of him as of his predecessors. In a letter written just after the delivery of his inaugural address to the students at the Academy, he remarks:—"I notice you have begun to speak of me as 'Professor Street.' I hardly know myself under that designation, and should, indeed, be glad if you would not continue to use it." Whether this disinclination to wear titles would have extended so far as a refusal of that which must, sooner or later, have been pressed on his acceptance on the completion of his great work, we cannot say; upon all such titular distinctions, at any rate, he could well afford to look with contempt.

The Dean of Westminster has, in accordance with the prayer of the council of the Institute, supported by Sir Frederick Leighton, P.R.A., sanctioned the interment of the remains in Westminster Abbey, and the funeral will take place on Thursday next, the 29th December.

In the height of his fame, writes the *Guardian*, but before his work was done, has passed away one of our most distinguished architects. There is something more than usually pathetic and touching in the close of his brilliant career at such a moment. For the great work, which has employed him for so many years, and of which the manifold anxieties have probably tried his health and strength to the breaking strain, is upon the point of completion. It is as when the ship founders within sight of the port—as when the racer drops within reach of the goal. A work like that of the Law Courts could not go on without not merely much criticism, but much contradiction and dis-paragement. While gradually rising, and before the whole plan had disclosed itself, expressions of misgiving and disappointment might escape even friendly lips. But the architect, who saw the whole as it would be in imaginative vision, could look forward to the time when the effect of the completed whole would furnish his answer to objections founded on partial judgments, and justify his design by revealing the idea which had inspired it. We have seen successive portions of the building rise and extend themselves. We have seen scaffoldings disappear, and exhibit portion after portion of the finished, the highly finished, detail of the structure. A little while longer, and all that was planned would have been realised; and the architect would have had the knowledge that the work had received his care to the last, and that as a whole, and as perfect as he could make it, it represented what he intended. But there is a wide interval between *almost* and *completely*. He has not been allowed to see the end of the greatest of his efforts. Mr. Street's merits as an architect will be more properly judged elsewhere than in a hasty notice. But one or two points occur at once. No one had a greater sense of his calling as one of the fine arts. He studied it with enthusiasm, and with serious thought on its principles and purposes. He was an indefatigable observer, and his range of observation was very wide. He had a keen sense for all that is original and characteristic, and his ready and skilful pencil was always at command to record what he noted. And he himself in temper and genius was original and bold. Daring is not always a guarantee for success; but in Mr. Street's work there was always the mark of an idea which he wanted to express, and which he not seldom expressed with striking distinctness and nobleness, often with great beauty. But beauty was not what he first aimed at. It came, and it was welcomed, in the train of severe adaptation to the purpose in view, and with severe subjection of all subordinate detail and ornament to the main end and character of his work. But he never went out of his way to bring it in; he never sacrificed anything of truth and force to purchase it. He was a very genuine worker and a very genuine man. The Church has lost in him not merely a servant who thought nothing that his art could furnish too good for its service, but an intelligent and earnest member, who took the deepest interest in all that concerned its hopes and its difficulties. He has left his mark in great and

well-known churches, with which the world is familiar. But there are not a few persons, we imagine, who can remember how in some obscure country parish, Mr. Street has given ungrudgingly time and thought and pains, and has taken as much personal interest in making a plain village church suitable for G.D.'s worship, in all soundness of work and fitness of arrangements, as if he was watching over the rising magnificence of a cathedral. The Church and the clergy of England owe him a great debt, not merely for the work which he has done, but for the example which he set of religious devotion in the application of his art, and for the conscientious care which he showed that what he undertook for religion should be carried out as worthy of a purpose which he thought the highest an artist can set before himself.

Of Mr. Street's works we have illustrated the following:—New Law Courts, original block plan in the *Building News* for Feb. 22, 1867; original design (bird's-eye view) May 24, 1867 (N.E. angle) June 7, 1867 (interior of central hall), Sept. 3, 1867; (Strand front and new Temple Bar) June 26, 1868; the Embankment design, April 23 and May 3, 1871; the accepted design as carried out (Strand front), Nov. 17 and Dec. 8, 1871; (public staircase to galleries), Dec. 1, 1871; (interior central hall), Sept. 26, 1873. Cathedrals: Christ Church, Dublin, restoration, May 26, 1871; (St. Mary's Episcopal, Edinburgh, competition design), Jan. 10 and 17, 1873; (Bristol, new nave), Oct. 20, 1876, and Sept. 2, 1881. Convent (St. Margaret's, East Grinstead), Dec. 18, 1868. College (Wilberforce mem., Cuddesdon), Aug. 6, 1873. Churches (SS. Philip and James, Oxford), Aug. 30, 1861, and Feb. 20, 1863. (St. James the Less, Garden-street, Westminster), May 2, 1862 (St. Mary, Stone, near Dartford), April 10, 1863, and June 23, 1866; (St. Peter, Burnmouth), Nov. 27, 1863, and May 3, 1879; (St. Mary, Clifton), Dec. 16, 1864 (and four page illustration), August 4, 1865; (do. *rescotos in*), May 9, 1873; ("Crimean memorial, Constantinople"), Aug. 21, 1878; (St. John, Torquay), Oct. 16, 1868; (Teddington-park, Cheltenham), Jan. 7, 1870; (St. Saviour, Eastbourne), July 15, 1870; (Teddington), Dec. 20, 1871; (English ch. Rome, selected design for), May 24, 1872; (St. John, Moordown, Burnmouth), Aug. 29, 1873; (Kingsmead, Dorset), Sept. 4, 1874; (St. Mary, Southampton, D.C.), 21, 1877; (St. Mary, Speenhamland, Newbury), May 30, 1879; (St. Mary, Holmbury, Dorset), Sept. 19, 1879; (St. Mary, Monmouth, restoration and additions), Oct. 31, 1879. Rectory (Wigan), Oct. 3, 1873. Memorial brass (Sir Gilbert Scott, Westminster Abbey), Sept. 12, 1879.

Among his published works are: "Distinctive Features of the Middle Pointed Churches of Cornwall," a pamphlet, 1850; "Churches at Lubeck," pamphlet, 1854; "Brick and Marble in the Middle Ages; Notes of a Tour in the North of Italy," with illustrations by the author, issued in 1858; "Urgent Plea for the Revival of the True Principles of Architecture in the Public Buildings of Oxford University," 1858; "Architecture in the Thirteenth Century," 1863; "Gothic Architecture in Spain," 1865; "The Study of Foreign Gothic Architecture, and its Influence on English Art," 1868; "Report to the Dean and Chapter of Christ Church Cathedral, Dublin," 1868; "The Site of the New Law Courts," a correspondence with the late Prof. E. M. Barry, extending over 1869-72; "The New Courts of Justice," a reply to Mr. Jas. Ferguson and others, 1872; "Remarks and Suggestions on the Scheme for the Completion of St. Paul's Cathedral," in which the author proposes to retain the choir as at present, but to erect a second altar under the dome—in 1878. In 1858 Mr. Street drew the illustrations to the Rev. J. Barrow's book on "Soulmore Organs," and in 1869 he read a paper on Cathedrals at the Liverpool Church Congress. Before the Royal Institute of British Architects Mr. Street read the following papers:—"Churches of Le Puy en Velay in Auvergne," in January, 1861; "Restoration of St. Michael Penkevel Church, Cornwall," in December, 1862; "English Woodwork in the 13th and 14th Centuries," February, 1865; "Differences of Style in Old Buildings," November, 1869; and his inaugural address at the opening of the present session on the 7th ult., which will be fresh in the memory of all.

FINE AND DECORATIVE ART EXHIBITION.

THE second exhibition of pictures and works of decorative art was opened at the "European" Galleries, New Bond-street, last week. The collection of oil-paintings and water-colour drawings, which is, we understand, a new feature of this exhibition, comprises many works by artists of repute. On the first floor the visitor will find several noticeable pictures. L. Valles, in the "Poisoning Scene in Hamlet" (214), has been happy in the grouping and colour of his admirable picture. "Night and Sleep" is an imaginative study by E. Pickering, who has certainly caught somewhat of the spirit of Mr. Burne-Jones' style, though at some distance. One of the finest

marine subjects is Walter Shaw's "Off the Coast of Cornwall"—a very fine example of this artist's skill as a marine painter; the reflection of the setting sun on the water, the splash and spray of the waves as they rebound from the rocky headland, are painted with much technical power. We notice also No. 222, 235, and J. Pettie's "Lady of the 17th Century," as pictures of mark. A. Ludovici, jun., is the painter of two clever studies, "Clown" and "Pantaloone," and J. R. Herbert, R.A., contributes, "The Ridge of Hampstead Heath," known as the "Painters' Walk," "Ups and Downs," "Windsor Castle," and other landscapes, in his finished style of execution. Clara Montalbi's "Funeral at Venice" (250), a large picture, of considerable power, is full of the poetic feeling and luminous atmosphere which characterise this lady's work; the architecture is the least satisfactory part of the performance. "La Manola au Balcon" (258), a dark Spanish lady at a balcony, by A. Robert; J. E. Maxfield's "Young Lord," H. Muckley's "Flowers" (269), F. W. Topham's "Christening Party" (272), C. Calthrop's "In the Garden," are all admirable. We must notice also in praise a reduced copy of L. Filde's Royal Academy picture "Betty," a well-known and pleasant study of a girl coming out of a corn-field with a bucket on her arm; E. Barclay's "A Kabyle Woodman" (284), A. Bouchet's "A Negro Melodist," both feelingly painted, and a very pleasant group, "Still Life" (313), by S. Carter, jun., and the admirable truthful little study, "The Brook Side," by R. Collinson, next. "The Border Country," by J. W. Oakes, A.R.A., is thoroughly natural and vigorous in handling. The wild expanse of moorland, backed by dark mountain, and the grassy foreground are painted with much real feeling and power. E. Parton's "Still Pool," is another large picture of merit. We notice a replica of A. Ludovici's, "Le Feu Follet," in the Suffolk-street Gallery; and on the screen we remark several pictures by eminent masters. "Dwellers in Tents" (339), by F. Goodall, R.A. "The Shoemaker's Shop" (340), a lightly sketched study, by Capo Bianchi. J. Ammonier's "View in the Cotswold Hills" (341), "Emblems of Life," by J. R. Herbert, R.A., and a charming bit of finished execution and colour, "A Stranger in my Studio," by L. Alma Tadema, R.A., equal to this master's power as a delineator of *objets de luxe*.

"The Boyhood of Raleigh," by J. E. Millais, R.A., a study for a picture at the Academy is broadly painted in Mr. Millais's best manner. The young navigator is seated on the shore, his hands folded across his knees. A. Hennebiq in 356 has a highly finished incident, "A Sale of Objects of Art" (356), in which the grouping of the dealers in curios is excellent. No. 354 is a clever twilight effect.

The water-colours comprise several works of merit. Towneley Green's "Windfalls," Birket Foster's "Rome" (124), G. Truefit's "Design for Houses at Worthing" may be noticed in passing through the gallery. Madame de Cool has some choice paintings of flowers, No. 146, for example, crisp in drawing and rich in colour. No. 147 is another group of drooping tulips, very cleverly drawn. Kate Hastings sends "Autumn" (153) and "Spring," two studies in a light decorative key of colour. "Leaves from a Sketchbook," by Bernard Evans (168), is clever; we notice also a feeling sketch of "Cornfield," by J. Syer, jun.; J. D. Linton's "Day Dreams," a cleverly-drawn study of two girls, draped in yellow and scarlet—two colours which hardly blend agreeably. "Buy an Apple, Sir," is a skilful drawing of a little girl by Adrian Stokes. J. Orrock sends a pleasing landscape (174)—we note the same artist's clever sketch of oak, "In Charnwood" (185); a view of Abergavenny,

by H. Canty; "Lincoln," by A. B. Donaldson (191), and two clever sketches by Bernard Evans (193, 194), broadly handled, of "Summer and Winter." The wild winter's night depicted in 194 is drawn with much vigour. The same artist's view of Barmouth from the hills has fine depth of tone: the round-headed trees and distant blue sea have an almost oil-like opacity. Drawings in monochrome, and several etchings and engravings, are on view.

The works of decorative art are interesting. Chief among these we may draw attention to Felix and Wayman's art furniture. The cabinets, and Chippendale and Heppelwhite chairs in mahogany are good reproductions of the 18th century style. Maw and Co., Broseley, contribute specimens of mosaic tiles and pavements in Anglo-Roman style, some well-designed conventional floral tiles, hand-painted, intended for fireplace decorations, &c. We note, also, a display of art tiles by J. R. Thomson, Southwark, and painted plates by Bessie Guillod and Mrs. Mallam. A case of very fine faience by Boulenger and Co., Choisy-le-Roi, Seine, is on view, the faience being delicate cream colour, with ornament in alto relievo, decorated with gold, also *pâtes sur pâtes*, &c. E. Tourteau is also exhibitor of some choice faience, painted plaques, &c., worth notice. A pair of cloisonné enamel Chinese vases, by Mr. W. F. Ingram; and a case of Limoges enamels deserve attention for their beauty and delicacy of execution; also a case of rare goldsmith's work and jewellery by Messrs. Haneock. Choice specimens of Henri-Deux ware, by H. Boulenger, and of modelled faience, barbotine and plaques by E. Schopin; and bijouterie, painted in enamel, and some terra-cotta ware are exhibited.

Several examples of tapestry, by J. Hungerford Pollen, decorative panels by A. H. S. Westlake and B. Guillod, and ceilings are on view; we notice a very rich wall-decoration by G. C. Haite, in which the "Sunflower" has been adopted. The foliage and flowers are boldly drawn on a gold ground, with a dark dado. Messrs. Wylie and Lockhead, Glasgow, are the exhibitors. A design for a chimney-piece frieze in marble is also shown. The Lincrusta-Walton and the Papyrotile Company have specimens of their respective wall decorations well worthy of inspection. We must mention also some memorial and other brasswork by T. J. Gawthorp, Long Acre, and a terra-cotta statuette, the "Mother of Moses," by T. N. MacLean. The Ceramic Goods Co. have a stand of specimens of their hardware, called "inlaid chromo-litho vitreous ware," in various colours. The designs on the plates and vases are inlaid, and the colours are in good taste. The ware stands any amount of scratching or rough usage, and is extremely hard and durable, and likely to come into general requisition for artistic purposes. The Decorative Needlework Society have specimens of some choice embroidery and screens, and the decorative needlework of the College, Stratford, &c., may be looked at. There are also examples of decorative ironwork or enamelled iron by Willing and Co.; some wrought-iron lamps by L. Wilhelm, and other metal work, may be noticed. The model stamps for stamping designs and patterns on linen and fabrics for embroidery, shown by Hans Denk, are worth the visitor's attention. Those interested in decoration, French art faience, sculpture, tapestries, enamels, and jewellery, will be repaid by a glance at the European galleries.

SOME NOTES ON ANCIENT FLOORS.

IT may not be generally known that floors have attached to them a history which, to be made interesting, requires only to be

* The late Mr. W. Burges, A.R.A., won the competition for this church, but Mr. Street, who was placed second, carried out the work.

chap'ered out into dates or periods by the technically educated chronologist.

The use of floors for dwelling-houses—and under the name “floors,” we are referring mainly to the surface covering of floors, such a surface as flooring boards nowadays usually supply—is one of such antiquity that a history of floors is to be dated back to the most remote times.

Far away into by-gone ages, and long before a primitive civilisation created for the nineteenth and following centuries, records of flooring, or any other forms of architecture, the cave-dwelling tribes of these islands made for themselves floors to render warm and dry their secret recesses. Had we time and space at our disposal, we should experience no great amount of difficulty in tracing the progress of architectural civilisation, from the times when these barbaric tribes strewed over their cave-bottoms bundles of dried rushes, to later days when powdered and dampened clay, mixed with these rushes, rendered the same floor more or less damp-proof, and passing onward, and over the period when mosaic and tiled floors were common, to the introduction of wooden floors, until, eventually, we arrived at the times when those what may justly be termed “Art Floors” were constructed, we could refer our readers to those splendid specimens of parquetry flooring now to be seen in most of the European capitals. The palaces of the nobility of Russia contain some of the finest examples of mosaic wooden floors, and there are many of these of which it may truly be said that they are of wondrous splendour. Perhaps the most wonderful of all these specimens are to be met with in the palaces of the Czar of Russia.

There are large floors in the Winter Palace of the Czar, constructed entirely of small squares of tropical woods, and it is said that one of these large spaces is made up of pieces of wood, none of which exceeds an inch square in size. In the Summer Palace of the Czar of Russia there is, in particular, one splendid specimen of mosaic flooring. It is entirely made up of small squares of ebony wood, extravagantly inlaid with mother-of-pearl.

But although the subject or history of floors is not to be treated in this paper other than in a discursive way, there is, nevertheless, sufficient space at disposal wherein to touch upon a good many matters of interest connected with the floors of by-gone periods. We have had furnished to us, by means of the recent excavations, conducted by Dr. Schliemann at Troy, examples of the floors of the flint or pre-historic age. It is extremely unlikely that there will ever be any earlier examples than these furnished to us. The floors brought to light are found to have been made by means of reeds having been laid across the posts, and then covered with powdered clay. This primitive form of manufacture, and one which is adopted by some of the birds of the air in the building of their nests, has formed the basis of a plan for several of the patented floors of recent days.

We do not find that floors were ever boarded over with wood until houses had attached to them an upper story. There have been a good many examples of ancient floors preserved by the great eruption of the volcano Vesuvius, which, in A.D. 79, overwhelmed the Cities of Stabiae, Herculaneum, and Pompeii, and which caused them to lie buried under horizontal beds of loose tufa and lapilli until the middle of the 15th century. The disentanglement of Pompeii, which began in 1755, has brought to light valuable specimens of mosaic and tile-flooring, which the extravagant luxury of the age greatly affected. Some of these floors are made of marble. In no instance can it be found that wood has been employed. The extraordinary freshness of the

colours of the unearthed floors at Pompeii, and their great beauty of design, show clearly enough that in those days to the securing of an elegant floor a great amount of attention was paid.

We are not able to find any distinct records of wood having been employed for the boarding of the floors of dwelling-houses until towards the latter part of the middle ages, when an upper story began to be attached to middle-class houses in consequence of the increased value of land. The most abundant specimens of these early wooden floors are to be met with in London, probably for the reason that land being of higher values there than elsewhere, upper-storied houses were more common. The name of “lofts” was given to these upper storied rooms on their first introduction, from whence we have the compound word sentence of “up-a-loft,” and the word “cock-loft” has, probably, the same derivation, for we find it now to be occasionally employed in some of the villages in the Midland counties to signify an up-stairs bedroom.

Wooden floors appear to have had their origin in Sweden, and this, probably, for the reason that wood was there the most convenient and abundant material at hand. With the rude implements and tools common in Sweden two or more centuries ago, and with the primitive notions of joinery which the inhabitants possessed, very rude flooring-boards were, as might have been expected, turned out. For instance, no attempt was made to reduce the flooring-boards to a parallel width. On the contrary, they were laid down with all the natural taper of the tree, from which they had been cut, preserved. By reversing each board, however, and by placing together alternately a broad and narrow-ended board, a tolerably close-jointed floor was secured, although a rather peculiar appearance was the result.

Those wooden floors are yet exceedingly common in all parts of Scandinavia, and the primitive method of manufacturing them is resorted to in some parts of Sweden and Norway at the present day. The Early English custom, now out of date, of strewing rushes over the floors, as a sign of welcome to coming guests, is still common in all parts of Sweden, although the tassels of pine-trees are there substituted for the rushes, on account of the resinous exhalations which the pine-leaves emit, and which are greatly esteemed by the Swedes for their supposed hygienic properties.

In England, and just previous to the general introduction of wood flooring-boards, the floors of dwelling-houses were mostly made by plastering a concrete preparation over reeds, the latter of which were fastened to the joists. When the concrete became dry it assumed the character of a solid slab of unbroken stone, and inasmuch as it was strong enough to bear a heavy load of itself, without the aid of the supporting joists, and because it was fireproof, the plan produced a good floor. Its demerit was that it struck cold, even through the carpet with which it was usually covered. A good many examples of these concrete floors are to be found in the country-houses throughout the Midland Counties of England, and most of them are in a most excellent state of preservation—thus proving that they are of a very lasting character. Two cogent circumstances induced to the general adoption of wooden floors. These were, firstly, the repeal of the duties placed upon foreign timber; and secondly, the introduction of steam-power planing-machinery. At the time that all flooring-boards were laboriously planed by means of hand-labour, as alluded to in our article in last week's issue of the BUILDING NEWS, entitled “Some Notes on Flooring Boards,” and when the duty upon foreign timber

added greatly to the cost of wooden floors, such floors were esteemed too much of a luxury to be covered over with carpet. A perfectly clean floor was then the delight of housekeepers, and a considerable amount of pains was bestowed upon the securing of one. For mansions and palaces English oak was usually employed, although fir-wood was nearly as much esteemed, and indeed, was almost as expensive, for the imported logs were sold at 4s. to 5s. per cubic foot. As will be seen by the subjoined sec-

tional sketches, about half, or nearly half, of the wood was not used.

The feather or grain of the firwood boards was highly esteemed, and it was displayed with as much effect as possible. The worst effect arising from strongly-grained wood being employed for flooring-boards was that, not being protected with any sort of covering, the grain soon worked up under the action of traffic into splinters, and occasionally very serious accidents resulted therefrom. The logs out of which the boards were sawn were imported either from Archangel or St. Petersburg, and for the purpose of flooring they were always selected with peculiar care. They usually came in sizes varying from 15 to 18 in. square. There are no similar logs reaching

this country nowadays, the wood being always sawn into deals or boards on the other side, and so reaching us in a converted form. The annexed sketch, showing in what manner the boards were cut out of the logs, explains with what care the sap-wood and the shaken part of the heart were avoided, and it will also show how the feathered or grained wood was secured.

The logs were cut by hand-sawyers, who were, for the most part, a drunken and degraded lot of workmen—men whose presence could never be relied upon, and who

in consequence of the demand there existed for them, gave themselves such "airs and graces" as to earn for themselves the ironical title of "lords of the building trade."

Of course, the system of cutting the logs varied somewhat in accordance with the peculiarity of the log being cut, but the main principle, as shown in the sketch, was adhered to.

The boards, being planed, were put together with dowels, and any show of nails was most carefully hidden. Being laid, it was customary to keep the boards bright by applying a preparation of beeswax, and, with the aid of a large amount of "elbow-grease," a really beautiful floor was obtained. The economy and practicability of using machine-prepared flooring-boards, which have been furnished by the steam-power planing-machine, have caused these floors to be things of the past, and, although a good number of examples of these floors still exist in our old houses, we feel justified in ranking them under the title of "ancient floors."

We have, for the present, exhausted the subject of ancient floors, so far as we have felt justified in entering upon the details associated with them. Our sketch-paper, for it cannot be deemed to be anything more, has merely touched upon a history which, extended, is capable of furnishing material enough for a folio volume. But, before we place aside our pen, we desire to call the attention of architects to the eminent practicability of employing some of the beautifully-coloured and figured woods of the tropics for flooring purposes. There is mahogany, for instance, which would provide a floor that even our fastidious ancestors might well envy. Good straight, well-coloured mahogany logs can be bought for about 4d. to 5d. per superficial foot of inch thick (nett measure). In well selected logs there should not occur more than about one-fifth of waste.

Reckoning 3d. per foot for the machine work required to be done in the cutting of the logs and in the planing of the boards, it will be seen that prepared mahogany flooring-boards could be produced at about 7d. per foot at the most, or about 58s. per square, which is not more than an ordinary wooden floor costs when covered with carpet. For library or smoking-room floors mahogany would be highly suitable, and nothing could surpass it for beauty. There are other goods to be got which are cheaper than mahogany—American walnut, for instance—which would also make an elegant floor; but to the former wood we attach our preference. It has many qualities to recommend it; its beauty of grain, its rich colour, its unshrinking character, its tenacity with which it holds to nails, and lastly, the fire-resisting quality which it unquestionably possesses.

TECHNICAL EDUCATION AND ART WORKMANSHIP.

IT would be very hard to find a subject connected with art in these latter days of more import than that of what is so familiarly termed, Technical Education, and that this is so is sufficiently proved by the fact that an English Royal Commission on Technical Education has been busy in Paris for some time past in visiting the higher, the secondary, and the primary instruction schools, and more especially and particularly those in which manual and technical instruction is provided. Their special object, we are told, is to inquire into the education of those engaged in "manufacturing" and industrial pursuits, and includes the bearing of that instruction on the industry of the country in which it is given. Their commission is thus not a little wide and comprehensive, for they are to enquire into the state of instruction in

the districts in which cotton, woollen, and silk manufactures are carried on; and, also, which so nearly touches ourselves, into the pottery manufacture as it now is in other countries, and to find out what are the resources available for the like purpose in the pottery districts in this England of ours. Truly a subject of no small interest. The commissioners have, it would appear, already commenced their labours by visiting Yorkshire and Staffordshire. It is also the intention of the commissioners to visit Germany, and they have, indeed, as it is, already set on foot, in Berlin, some preliminary investigations.

Now this, as it appears to us, is a very important matter, and when looked into closely, exhibits a state of things not a little curious and instructive; for might we not in the first place ask how it is that we, who have had an architecture for some centuries in the past of our own, need to go into foreign parts for any such purpose as is here indicated? For it is to be observed that we are going into far off places, not simply to learn what they in foreign parts are doing, for purposes of simple comparison, but to learn a something and a somewhat of them, and then to profit in some way or the other by it; and, in short, if truth must be told, to copy their ways of work, if not the very work itself. But few will, in all probability, demur to this; but if any do so it may, perchance, occur to them to ask how it is that we are not sufficient unto ourselves, and able, not only to do our own work, whatever it may be, in our own way, but to offer it to others as exemplars of that nationalised and individualised work, and as evidence too of what we, as a distinct nationality, can do in art in this nineteenth century, and what the results are of our educational system, in so far as it influences fine art, and the production of objects of fine art. It would be impossible, as we take it, to find a subject of more curious and instructive import than this, however looked at.

And here, in the first place, let it be observed that the especial object of the commissioners is to ascertain what the foreign systems are of fine-art instructions, and what they are now doing in the "drilling" (there is no better or more accurately descriptive word) of bodies of students or workmen and workwomen, in the manipulative power, and in combination towards the production of a given art result, as a plate, or a dish, or a cup or saucer, confining ourselves, by way of illustration and simplicity of outlook, to works in clay and china-ware. There is no better or more useful illustration possible, or one more universal in its application. It would be impossible to do without art, and fine art, in the production of objects of burnt clay. No mere goodness of form—mere form, or outline—will suffice. There must needs be more than this: there must be drawing, and outlines, and colour, and even pictures in it and on it; and the great question then really is not alone who is to do this, but how is it to be best done, and what is the best system, or practical way of doing it. And here it is that we may well go back into the past of things, and into far-off and distant countries, and centres of art action to find out what has been done, in them, under conditions so widely different from anything we see, or can find, round and about us, always bearing in mind that in this, our clay machinery, of which the old world never dreamed, can, if need be, do all but the whole of the work.

We shall then look forward, with no small curiosity and interest, to the report of this commission of inquiry into such a subject, for it is only by inquiry on the spot, and in each special spot, that thorough and exhaustive answers can be got to the many and great questions involved. We do not dare to anticipate what the result of this inquiry may be; but there can be but little doubt,

that in these days, and certainly in all civilised, and the highly civilised centres of Europe, e.g., Paris, Berlin, and the other great centres of art manufacture, the system in the main is the very same, and that the work, whatever it be, is more or less divided, and that the object, whatever it is, is the production of a given number of hands, and that the same object passes perhaps through a number of stages, and that the very simplest and most common object, designed and manufactured, is the result of an ingenious application of art labour ingeniously divided, and so apportioned, as to most economically utilise the artistic and manipulative power of each workman, as a working force, the design being already prepared for him or them. We had from the late Herbert Minton, the well known manufacturer, some important details of his mode of work in vogue in his own manufactory and workshops, and he always contended that the division of labour, thus applied, was a necessary consequence of our modern idea of art, and art manufacture.

But how different all this, whatever its advantages or disadvantages, from the old-world and antique way of work, and how different the art action of the workman and workmen who, in past days, did bring such objects into the world's markets, or into their own markets. We are often reminded, in one way or another, of this wonderful power of organisation, and of the wonderful results of this division of labour, whereby an object, or rather the raw materials for it, enter at one door of a long room, and after passing through a number of "hands," each doing a little to it, passes out of the opposite doorway a finished and complete art object, and the more fully and in detail this can be done, no man working with his right hand knowing what his left is doing, and the more effective the organisation which produces it, the better is it fitted for the world's market, and the cheaper it is, and, consequently, the more widely diffused. Indeed, as Minton boasted, it then must needs go round the world, and it certainly does so, and it may, therefore, be a question indeed, as to how far, and how deeply education has helped, and how far it is likely to help, or to hinder, its development in the future. And this, as must be admitted, depends a good deal as to what is meant by "education" in its art aspect, and as to its influence on the mind, and even manual power, of the executive workman; and more than all, as to how far, and in what way, he can, as an individual, make use of it, and thus compel the world to look at his work.

How curious, then, it would be if the imperial commissioners, after looking at the now so universal ways of work, as they are doing, could, but for a short hour, get but a glimpse of, say, an "Etruscan" workshop, such a one as must have been common when the famous "vases" were moulded into form and painted, and could they, at the same time, get to see, for a passing moment, the workmen at their work. The shop, itself, could have been but a rough one, and the mechanical appliances but of rude construction; no steam-engine most certainly, and the *modus operandi* of the human element in this rough workshop would, indeed, have surprised the imperial commission, for each individual workman must needs have been an artist himself. Let the vase-room in any one of the capital cities they visit bear its testimony to this, and the longer, and more closely the objects, one by one, are looked at and studied, the more emphatically will the truth of it assert itself. In the rough days of the old world, the workman was himself an artist, however rough and uncultured he might be, and our own museums, and those on the Continent, sufficiently prove and bear this out, for in them we do, indeed, see, not alone the work itself, e.g., a Greek vase, and its form, and outline, and

the drawing in it, and the painting; but we do see as well, not alone the workmen, but the workman, and the artist, however rude. We cannot but hope that the imperial commissioners will look well into this phase of this curious subject. C. B. A.

OBITUARY.

DECIMUS BURTON.

IN Mr. Decimus Burton the profession has lost one of the few surviving links which connected the present with the past generation of architects. Mr. Burton was one of a band of architects of which Holland and Nash were the leaders. He was born in 1800, and was the son of Jas. Burton, the only survivor of the family. In his father's office, and that of the late Mr. Geo. Maddox, he received his architectural education. His principal works were commenced between 1823 and 1826. These comprise Holwood House, Kent; improvements at Tunbridge Wells for Mr. J. Ward; and at the same time Grove House, Regent's Park, for Mr. G. Greenough; and the Colosseneum, Regent's Park, for Mr. Thos. Horner. From 1826 to 1841 Mr. Burton was engaged on the buildings in the Zoological Society's Gardens, and from 1825 to 1846 he was employed in the design of the improvements and entrances at Hyde Park. The Royal entrance in Constitution Hill was from his design, but was not carried out in its integrity, and we believe was always a source of disappointment to the architect. His other principal works are the mansions of Lord de Clifford and Lord Stuart de Rothesay; the Athenaeum Club House, Pall Mall; Halford House, Regent's Park; Charing-cross Hospital, Rectory, Sevenoaks; additions to Pains Hill and to East Cliff House, Ramsgate, for Sir Moses Montefiore; Devonshire House staircase; the Marquis of Hertford's villa, Regent's Park; Broom's Hill; Burrwood; Boreham; Club Chambers, Regent's-street; Grimstone Park Mansion, Yorkshire, for Lord Howden; the United Service Club improvements; Dublin Phoenix Park improvements, the latter from 1834 to 1849. He was also architect to the Royal Botanic Society from 1840 to 1850, for which he designed all the principal buildings which were executed under his direction. Among other houses are Stanwick, built for Lord Prudhoe; Carlton House, Bentham Hill; Penhurst, Oakland; and Cagburn, Hastings. One of his chief works was the Palm House and Winter Garden at Kew, an illustration and details of which we gave last year, and which our readers may remember led to a question of the real authorship of the design. Mr. Burton's favourite style was monumental, and adapted itself to the public edifices he was called upon to design, but was ill-suited for domestic buildings, a branch of practice in which he ultimately managed to secure a large share. He, in fact, relinquished public works from a desire to avoid the disappointments and vexations incidental to it. One of his most successful designs for residences was the Doric villa he built in Regent's Park for Mr. G. B. Greenough. The portico in *antae*, and the circular bay with engaged columns group pleasingly together. Mr. Burton was at least skilful in making the severe Greek forms adapt themselves to domestic buildings, and some of his best designs show success in adapting the style for modern use; but the rising school of Gothicism were beginning to create a distaste for this inflexible style, and Mr. Burton, like a few others of his school, turned their hands to the design of Gothic houses, many of which he erected. Grimstone House, Yorkshire, is one of the most successful of his Classic residences. The design partakes of an Italian character, and its long front, enriched by an open order and a campanile at one end, is an example of Mr. Burton's taste as a designer.

Mr. Burton had a cottage residence at St. Leonard-on-Sea, a place his father started; but he lately came to live in his town residence, 1, Gloucester-house, Gloucester-terrace, Hyde-park, where he died last Wednesday week, at the advanced age of 81. He was never married. His remains were interred on Tuesday last at Kensal Green Cemetery. Mr. Decimus Burton was made a Fellow of the Institute of British Architects in 1834, and with the excep-

tion of his intimate friend, Professor Donaldson, was the oldest member of the Institute, has filled the office of vice-president, and was a donor to the funds of that body. He was also a Fellow of the Royal Society, and a Fellow of the Society of Antiquaries.

ANTHONY SALVIN.

The announcement of the death of Mr. Anthony Salvin, F.S.A., an event which occurred on Sunday morning, at his residence, Hawksfold, Fernhurst, Hazelmere, carries us back to the earliest days of the Gothic revival. The late Mr. Salvin, who has died in his 83rd year, commenced practice nearly sixty years ago, at a time when the enthusiasm of architectural students had been aroused by the recent publication of the elder Rickman's "Attempt to Discriminate the Styles of English Architecture," and early attracted attention by his adaptation of the formal Late Gothic, just then rising into favour in domestic work. Although he showed in his subsequent practice that he could work in all phases of English Gothic, from what was then considered Late Norman to fully-developed Tudor and even Renaissance, this Early Fifteenth-century style was that in which those which will be permanently regarded as his most successful works were carried out, and in all an infusion of a Scottish element, due to his early associations, is evident. As an architect, his works, which were to a very large extent executed for members of the aristocracy, were marked by a taste and a refinement much in advance of his age. Much of his earlier church work he would, doubtless, in his later years have been glad to have seen effaced; but the true principles of four Mediaeval ecclesiastical architecture were not fully comprehended in those days, and it should also be remembered that a church architect half a century ago had to educate and vigilantly watch at every turn not only his assistants, but yet more his builders and their foremen. Mr. Salvin was a well-read and accomplished gentleman; a good linguist, and an artist of great ability, but of such extremely retiring manners that his high attainments and social qualities were little known beyond a small circle. It is probably due to this cause—to his marked diffidence as to his own powers, and possibly to some extent to his commencing practice with the ambiguous advantage of possessing large private means independently of his profession, that he never became conspicuous in the learned societies to which he belonged, nor contributed papers to the Institute or the other bodies with which he was associated. He was a quick and vigorous draughtsman, and would with great rapidity sketch, always in perspective, for a client his ideas of what should be done. In the decoration of buildings he displayed a rich elaboration, which, in its day, was highly admired, and a fine sense of colour harmony, which will give his works a lasting interest. Mr. Salvin's earliest building of note was Moreby Hall, near York, built for Mr. H. Preston, a Tudor building of brick, faced with stone, with mullions and double transoms to windows, which was erected between 1828 and 1832. Mamhead, near Exeter, the seat of Mr. Robert Newman, was begun in the former year, and was not completed till 1838; it is entirely built of stone, and is a work of considerable size and importance. In 1837 he carried out and fitted up Seaford Castle, Sussex, for Mr. Hussey in the same early 16th-century Baronial style. To attempt to give a complete list of Mr. Salvin's works would occupy more space than is at our disposal. His practice was very extensive, and included the repair of palaces, the erection and restoration of castles, mansions, cottages, lodges, colleges, cathedrals, churches, banks, hospitals, bridges, and every class of building. As architect to the last and present Dukes of Northumberland, and a valued friend and adviser of the former nobleman, he designed and superintended the execution of work to the extent of many hundreds of thousands, including Alwick Castle, six district churches in Northumberland, besides three in Tynemouth; many cottages, bridges, and other improvements to the estate, in addition to Albury House, which cost £34,000. It may be noted that in 1870, a few years before the demolition of Northumberland House in the Strand, he added a new ball-room to that mansion. For these works, for the heads of the Percy family, the late Mr. George Smith, of the firm of Smith and Co., was the builder. Among his

other works we may passingly enumerate, roughly following the order of execution—Brancepeth Castle, where he carried out alterations and additions at the beginning and near the close of his practice; Moreby Hall, 1828-33, which cost £10,000; Methley Hall, for Earl Mexborough, cost £17,000; the additions to Farham Hall, Framlingham, for the Hon. G. F. Curzon; Barworton House, for the Hon. G. F. Hamilton, afterwards Lord Boyne, in 1835; Cowsley Hall; Durham University, 1835-40; Observatory and Cathedral, 1844; Grey-stoke Castle, for the Hon. H. Howard; Rufford Abbey, in "the Dukeries," for the Earl of Seaborough, 1838-40; Warden Hall, Chorley, for Mr. Ffarington; at Cambridge, masters' lodge, 1842, and two new masters' courts to Trinity College, 1859-61, Perpendicular in style; the restoration of Holy Sepulchre ("Round") Church; and at much more recent dates Trinity Hall, the new Anatomical Schools, and the new buildings of Caius College, of Jacobean character; Kelham Hall, for Mr. Speaker Manners Sutton, afterwards Lord Canterbury; repairs to Carnarvon, Carlisle, and Newark-on-Trent Castles; Ilafod House, North Wales, the erection of which was entirely abandoned after £21,000 had been expended; Narwerth Hall for Earl Carlisle, 1846-8; Peckforton Castle, Tarporley, for Mr. (now Lord) Tolemache, 1846-50; a 13th-century stone building fitted in o.k.; Tabley House, Cheshire; restoration of the choir of Wells Cathedral; Flixton Hall, Bungay, for Sir R. A. Adair; restoration of Rockingham Castle and Lanercost Priory; Pattendale Hall; Gurney's Bank, Norwich; extensive works at Balliol College, Oxford; yacht club-houses at Queenstown and West Cowes; Keele Hall, Staffs, 1855-60; Marbury Hall, Cheshire, Italian in style; Congham, Norfolk; Crosscigge, Foresby, White (Cumberland), and Somerset halls; Dunster Castle, for Mr. Luttrell; Manchester Hall, Cumberland; Warwick Castle for a long period till 1866; additions to Encombe Hall, Dorset, for Earl Eldon, £40,000; additions to Budball House, £11,000; and Thorsby Hall, in the Dukeries, for Earl Manvers, in the Renaissance style, one of the most charming and effective of his works. At the Tower of London he carried out, during a long series of years, only ended in 1873, important works, including the restoration of the Traitors' Gate, Beauchamps, Saltery, White, and St. Thomas's Towers, and the adaptation of the latter for use as the jewel-room; and at Windsor Castle, the new and piquant roof to the Curfew Tower; the restoration of the Hundred Steps; of the Embankment-wall to High-street; Henry VII.'s library; the Canons' residences, &c. Mr. Salvin practically retired from the profession 10 years since, owing to feeble health, but continued a few of his works, perhaps the last to be given up being the important commissions for Lord Leconfield, the restoration of Petworth Castle, and the new town mansion in Chesterfield-gardens, which by his desire were transferred to his lifelong friend, the late Mr. T. H. Wyatt. Mr. Salvin was one of the senior members of the Royal Institute of British Architects, having been elected Fellow in 1836, two years after its foundation; but beyond serving the honorary office of Vice-President, he never took any prominent part in its management; in 1863 he was awarded the Royal Gold Medal. For many years he had been a Fellow of the Royal Society of Antiquaries.

Mr. Salvin married the daughter of the well-known landscape gardener, Mr. Nesfield, who predeceased him, and he leaves a son Osbert and two daughters. His eldest son, Anthony, followed the profession of an architect, having an office in Adam-street, Adelphi, but died last year. Of the elder Salvin's assistants we may mention his nephew, Mr. Robert Nesfield and Mr. R. Norman Shaw, R.A., the joint authors of the well-known "Sketches." The funeral of the subject of our notice takes place to-day (Friday), at the quiet country churchyard of New Ground, Fernhurst.

ARTHUR L. BRADBEER.

Mr. Arthur L. Bradbeer, of Lowestoft, one of the earliest and most constant of the members of our "Designing Club," has, after an illness of only four weeks, been removed by death. He was attached to Mr. Chenene, of Lowestoft, and for several months afterwards an assistant of Mr. Angelo W. R. Simpson, of Blackburn. Since then he has had the charge of a new hos-

pital at Worthing, and returned home for a holiday in October last, having seen the hospital completed. He took a chill, broke a blood-vessel, and rapid consumption of the lungs supervened, and he died on the 17th of November. He was making his way well upward in his profession, when suddenly, with scarcely any warning, he was called away at the early age of 24.

ALFRED JAMES HISCOCKS.

Mr. Alfred James Hiscocks, F.R.I.B.A., and L.M.S.A.S., died on Sunday at his residence, Alfred Lodge, East Hill, Wandsworth, in the 76th year of his age. Mr. Hiscocks had been for 37 years district surveyor of Wandsworth and Tooting, under the Metropolitan Board of Works and their predecessors. He joined the Institute as an Associate in 1838, and became a Fellow in 1866.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the ordinary meeting of the Royal Institute of British Architects, held at its rooms, 9, Conduit-street, W., on Monday, a paper on "The Artistic Treatment of Constructional Ironwork" was to have been read by Mr. Hugh Stannus, Associate; but, in view of the recent death of the President, Mr. G. E. Street, R.A., it was deemed advisable by the Council that the communication should be postponed. A letter of condolence from the hon. secretaries of the Architectural Association having been read, Professor HAYTER LEWIS, Vice-President, said:—Before I allude to the event which has just taken place, I have also the very unpleasant task of referring to the deaths of two other of our distinguished members and past vice-presidents, Mr. Anthony Salvin and Mr. Decimus Burton. Mr. Salvin was probably better known to the generation immediately before us than to the present, and he was known as a very earnest worker in the same cause as Mr. Street, whom he predeceased by but a single day. Many of our large castles and country seats owed their designs to him, and up to the latest period, I believe, his life was occupied in extensive restorations in London. Mr. Decimus Burton's works are well known. If I remember rightly, two of the clubs in Pall-mall—the Athenaeum and the Senior United—were his works, and you all know his work at the entrance to the Park. In his time there was no architect better known, and none ever more respected than Mr. Decimus Burton. I now have to allude to the business of this evening. The Council, of course, could not by any possibility postpone their meeting, the event having happened at so very recent a period. It was only about half-past ten on Sunday night that Mr. Street died. I told you at our last meeting that I had had an interview with him, and I likewise read a portion of a letter from his son, and I know what were the feelings of his physicians. Those feelings were decidedly hopeful, and the favourable signs continued throughout the week. Last Friday he was to have left town for Egypt, where he hoped to spend some short time in entire repose. It was a new country to him, and one which he always wished to see, and of which he would, no doubt, have made valuable use in his future writings. But, man proposes; God disposes. On Thursday afternoon, while sitting conversing with an old friend, an Academician, he was struck down heavily by a severe stroke of paralysis. The whole of the left side was paralysed, and he was rendered speechless. For some little time he was conscious. He suffered no pain, but from the first few hours after he was struck till he died he remained unconscious. He had, I need scarcely say, every possible advantage that the skill and science of physicians could bestow, and the love of his family and friends, and I hope you will not think me descending to trivialities if I add, the affectionate solicitude of the domestics about him. Mr. Street has been too much before the artistic world to need that I should give you much of his history, and you all knew him too well and respected him too highly to require that I should say much in his eulogy. To many of us he was known as a friend—heartily and cheery and ready of wit—giving and taking sallies and home-thrusts in the most playful way. Above all, he was sincere, fearless in asserting his own views, and no doubt sometimes came into collision with

others, towards whom he may have appeared to bear himself somewhat harshly. But who is there that feels strongly that does not speak and write strongly? And I know of no one to whom, from my personal knowledge of him, I could more closely apply the beautiful words of Shakespeare in the advice of Polonius to Laertes,—

"The friends thou hast, and their adoption trial,
Grapple them to thy soul with hooks of steel."

To all of us he was known as a skilful artist, a most powerful writer, a fearless champion of the views he considered right. Fearless of what others thought or of what the results to himself might be, he had the courage of his opinions, and he stuck to them through thick and thin, no matter what the loss of profit or place might be to him. To those who have known him by and in his works, he was a high-minded gentleman, a friend to all that was noble and true in art; ever ready to aid the progress of art in every shape, sparing no exertion of any kind that he thought needful, and attending to his work in all its details, which, indeed, he looked on as being as important as the whole design itself. He was an absolute master of every detail, and those who knew him well must often have been struck by his marvellous power of work. As an instance of this, I may tell you that in his great work, the New Law Courts, where there are hardly two windows or two doors which have the same moulding, there is not a single moulding from top to bottom which was not drawn out by himself in full size. Others will speak more worthily than I, but none can be more sensible of the loss of a dear friend, and no one can feel more keenly than I that a great power in art passed away when George Edmund Street died. It is hardly necessary for me to add that the Council have passed a resolution of condolence with the members of Mr. Street's family—his son, his brother, and his sister—and, as a mere form, I will ask your acquiescence in that resolution, for I am sure that you will all heartily and thoroughly endorse it. It is to the effect that the secretaries be requested to transmit to Mr. Arthur Edmund Street a letter in the name of the Council expressive of their sorrow, collectively and individually, at the loss they have sustained in the death of Mr. Street, and of condolence with the family in their sudden bereavement. I ask you to express your formal acquiescence in the action of the Council.

Mr. BEESFORD-HOPE, M.P., said:—I have a painful duty to discharge, and one which I should have shrunk from taking on myself; but, looking round the room, I find I enjoy the melancholy pre-eminence of being the senior past President here, and in that character I venture now to speak. I venture to come forward in this moment of solemn grief to make myself the mouthpiece of the Institute, as the institute, and not only of its governing body, to the world. In this dreadful year—forgive me if I talk with very strong personal feeling—in this dreadful year of 1881 we have been walking in *tenebris et umbrâ mortis*. I am glad there are only ten more days in this year to be passed, and I pray God they may not be days of catastrophe. I cannot help reflecting that it was just six weeks ago that I was standing up where I stand now, and was addressing him whom we now mourn, healthy, vigorous, earnest, delivering that grand, massive address, well argued, logical, powerful in tone, admirable in composition. We all were proud of him. Could any of us then have thought that in only six weeks we should have met as we are meeting here to-night? I feel that we have come to bury Cæsar, not to praise him, but we must say something. But you, Sir, have so clearly pointed out the great, good points of his grand character that I feel there is very little for me to add as to his honesty, his boldness, the way he conquered people by the conviction that about him was no trickery, no diplomacy in a bad sense, his fearless, earnest advocacy of what was right, and true, and beautiful—beautiful in the moral and in the material world. He has passed away young, but he has passed away in many ways full of honours; he has passed away our President; he has passed away ten years a Royal Academician; passed away just completing the monumental building of our own later generation—the New Law Courts. He has gone, following only by a short time his noble-hearted rival,

Burges. I could go on for a long time, but I should only by piling up words weaken the sorrow that wells up in our hearts. I move that that resolution be made the resolution of the Institute, and after that that we dismiss all other and less pressing business, and go away in sorrow to meditate on him we have lost, and to make him our personal and our artistic example of our own exertions.

Mr. CHARLES BARRY, Past-President, seconded the resolution. He could not forget that during the three years he occupied the chair of the Institute Mr. Street, as Vice-President, was his loyal coadjutor, a man much his superior in mental vigour and artistic power, but one who did not feel it inconsistent with the possession of those greater powers to give the chair every possible support. It was known, of course, that on certain points they thought it their duty to take different views, and had since followed opposite courses, but beyond that official difference of opinion the friendship between them, which had been the growth of many years and which was greatly cemented by their three years' association, never faltered for a moment.

The resolution was agreed to *sub silentio*.

Mr. HORACE JONES, V.P., City Architect, moved that as a fit tribute of respect to the memory of the deceased the business set down for the meeting be adjourned.

Mr. EWAN CHRISTIAN, V.P., seconded the motion, remarking that a great light had been quenched and that the art world had lost a prince and a leader.

The motion was at once agreed to, also in silence.

Mr. BARRY added that the senior Vice-President (Prof. Lewis) and the two secretaries had that day been appointed by the Council a committee to take such measures as they thought fit to do public honour to the memory of the late Mr. Street, and to make known to their friends, as well as time permitted, what arrangements would be made.

The proceedings then terminated.

LECTURES AT SMOKE ABATEMENT EXHIBITION.

AT the recent Smoke Abatement Exhibition Captain Douglas Galton, C.B., F.R.S., read a paper on "The Abatement of Smoke in Fires for Warming and Ventilation." We had now, he said, arrived at this point—that the absolute disappearance of smoke from manufacturing chimneys in England depended only upon the desire of the manufacturer himself to avoid smoke. It was certain also that if the smoke from domestic fires were stopped the manufacturers would soon follow the example, as smoke was only permitted to exist because the community was not sufficiently educated as yet to realise the necessity of getting rid of it. The removal of this nuisance would probably be a very slow matter, but it was indubitable that smoke seriously affected the health of those who breathed air polluted by it, and while it was not the only impurity of town air, it was a very serious one. The author referred to the fact that the evil of a polluted atmosphere in London was growing in an accelerated ratio, and now a persistent canopy hung over London which was only removed from one part of the metropolis to another by any but a very strong wind. He urged that all ventilating arrangements would be useless unless we could bring pure air through the ventilators. If it was admitted that pure air was a necessity we must be prepared to make some sacrifices in the warming arrangements in order to secure it. The methods of ventilating and warming in use in houses might be classed under three heads:—1st, the use of open fire-places; 2nd, close stoves or coils of pipes in the several rooms or passages; and 3rd, fresh air warmed either by a stove, or by hot-water pipes in the basement, and conveyed to rooms by flues. In the two last arrangements the coal could and should be burned without smoke. With the ordinary open fire there was more difficulty. The open fireplace of the old-fashioned pattern was undoubtedly the best engine of ventilation for a room; moreover, the open fire possessed many advantages as a means of warming. But with all its merits it was a relic of barbarism; and an ordinary open fire would not burn bituminous coal without smoke. In the Exhibition the numerous grates which claimed

to prevent the creation of smoke might be spoken of under three heads:—1st. Those which brought air warmed or otherwise to the top or back of the fire. The usual barrack fireplaces would, when the fire was attended to, prevent most of the smoke, and with trifling alterations would be almost entirely smoke-consuming. Under the same head Messrs. Burnard and Bishop exhibited, in the glow-grate, a fireplace which claimed to prevent smoke. Griffin's grate would also fall under this head. 2nd. Those which drew down the gases and flame through the fire to unite with warmed air, or otherwise, at the back, whence the gases passed up the chimney. Of this class the Derwent Foundry grate might be instanced as one form. 3rd. Those based on the principle of coking the coal before use. Of this class Dr. Arnett's was the earliest example; a method which had many adaptations in the Exhibition. 4th. Those which claimed to obtain a smokeless fire by means of smokeless coal. 5th. The plan of using coke and gas, as proposed by Dr. Siemens; or 6th. The combustion of gas on asbestos, or gas on fire-clay balls—the latter could only be classed as mere makeshifts which did not give the real advantages of the open fire. Unless the substantial advantages and comfort of the open fire were preserved, it was not worth while to retain it. If these substantial advantages had to be sacrificed in the prevention of the smoke, we might just as well face the question boldly and abolish the open fire. Having pointed out some of the disadvantages of the open fire, in wasted heat, labour, and force, Captain Galt said there were two other modes of conveying heat to rooms which might be adopted—gas and steam. In the first, we should continue to have separate fires, but we should have our fuel conveyed without labour to the point where wanted. If the gas companies would arrange to give gas suitable for heating purposes at a cheap rate, improved methods of employing the gas for warming and ventilation could easily be devised. At the present time, whilst great progress had been made in the application of gas as a fuel for cooking purposes, the arrangements for warming and ventilation had not been satisfactory; but that was because the price of gas for lighting purposes was too high to admit of its economical use simply as a fuel for warming and ventilation. In applying heat for ventilation, in which case the whole of the products of combustion of the coal would be utilised, it might be assumed that with coal at 20s. a ton, and gas at 3s. 4d. 1,000 cubic feet, gas would be seven times as dear as coal; but for heating purposes, where the whole of the products of the combustion of coal cannot be utilised, but where the heat given out by gas can be almost all made available, the cost with gas would vary from three to six times that of coal. In cooking, the actual cost of gas would be about three-and-a-half times that of coal. Where a coal fire had to be maintained all day to perform occasional work which could be done with gas in three or four hours, gas might be cheaper than coals. Moreover, the facility with which gas afforded of obtaining at a moment's notice a fire exactly suited to the requirements of the cook, compensated for the difference of cost. By the use of gas each individual created the heat he required in his own house, just as he would do with coal. Gas was simply a convenient form of fuel which conveyed itself wherever it was wanted, and created comparatively little dirt. But if gas was burned in a room, it consumed and vitiated the air of the room, unless accompanied by special ventilating appliances. The other system for avoiding the use of coal in houses was the use of steam, according to the system which had been adopted in the United States of North America, and which was called the "Combination System of Steam Heating." Under this system of steam heating, for towns and villages, of which Mr. Holly was the projector, the steam was supplied from a central fire to a large number of houses for domestic purposes, and thus the necessity of having separate fires in each house was avoided. In fact, by this system heat was supplied from some central place, just as water is supplied; so that each person could take, and pay for by meter, what heat he required, either for warming, ventilation, cooking, or washing, or for power in working machinery. Having given some details of the Holly system (which was fully described in our issue for October 14, page 491) the author added that

the loss by condensation in the street main had been ascertained to be not more than 2½ per cent., and the prices paid for heat in the United States were a lump sum of 8s. per 1,000 cubic feet of air-space per annum, or for an artisan's house about 10d. to 1s. 3d. a week. At these prices gas was about five times as expensive as steam, while the latter system would vastly diminish the risk of fire. In conclusion he said:—If we are to give up the open fire for heating, we must reconsider all our warming arrangements, and adopt a new starting-point. The arrangements hitherto suggested for applying gas to heating purposes are all of a makeshift character. They have been based upon the open fire or the coal stove. The gas fire is but a clumsy attempt to imitate the coal fire, without the charm and great merits which, with all its inconveniences, the open coal fire possesses. Similarly the arrangements for steam heating and for heating by hot water leave much to be desired in a hygienic point of view. Warmed air alone does not produce comfort, because it is less pleasant and invigorating to breathe than cold air, and it leaves the walls colder than the air of the room, and the heat of the body is radiated to the colder walls. To avoid this cause of discomfort, the temperature of the warmed air is frequently raised beyond what is either comfortable or healthy for breathing, and thus discomfort in one form or the other can with difficulty be avoided. To insure comfort it is essential to combine warmth in the walls and floors with cool air to breathe; as, for instance, air at a temperature of 54° to 58°. By the use of gas as a warming medium we might communicate warmth to skirtings or dados in a room, and thus avoid the uncomfortable feeling of radiating the heat from our bodies to the cold walls of the room. In a similar way, hot water or steam might be applied. Special arrangements must also be made for the change of air in a room. It is in these directions that we should seek to apply heat for warming purposes if the open fire is discontinued; but it would at the same time be necessary to make arrangements for the frequent change of the air of the room.

On Saturday afternoon, Mr. Thomas Fletcher, F.C.S., of Warrington, delivered an interesting lecture on the subject of "Economy of Fuel for Domestic Purposes," before a large audience at the Smoke and Fog Prevention Exhibition at South Kensington, which will be found fully reported in to-day's *English Mechanic and World of Science*. His object was to show, from his own practical experience, how, at a very small first cost, the coal consumption in private houses could be reduced to about one-half, with far less labour, dirt, and smoke. Taking for granted that the open fire will not be superseded in our time, he dwelt at some length on the momentous distinction between convected and radiant heat, and insisted that for economy of fuel, since all metals conducted the heat away and were bad radiators, no metal should be used in making grates unless absolutely necessary. Our first care must be, as far as possible, to encase our fires with a non-conductor, and the best was builders' fire-clay. It was shown how, by mixing this with silicate of soda, at 1s. 3d. a gallon, our present iron grates might be cheaply plastered over, or patched in case of cracks. He had thus adapted his own fireplaces. If building again, he said, he should build every fireplace entirely of bricks and tiles, using metal bars, two at most, in front only, the ends of which would be built into the bricks at the sides. As for the question of utilising the heat which escaped up the chimney, the lecturer said that in his own house the flues were built in inside walls, and were but half a brick thick. The back of the fire in one room did much towards heating the room behind it, and the warmth of the flues could be distinctly felt in every room up to the top of the house.

The second lecture in connection with the exhibition was given on Monday evening in the Lecture-hall, South Kensington, by Dr. Neale, on the subject of chemical lungs for purifying the air in workshops, hospitals, and the Underground Railway. The lecturer observed that impure air, especially when it reached the degree of foulness noticeable in the Underground Railway, was an evil with which all Londoners were painfully familiar. His remarks would have special reference to the condition of the air in the Underground tunnel, through which so many thousands of travellers passed every day;

and the apparatus which he would explain was the result of the conception that each train might be furnished with an artificial lung, by which the noxious gases generated might be consumed. These noxious products were carbonic acid gas, sulphur gases, and carbonic oxide. The carbonic oxide could not be got rid of by any chemical means; but much might be done to disinfect the vitiated atmosphere if the carbonic acid gas and the sulphur gases, which were the chief constituents of the air of the tunnel, could be exposed to the action of caustic alkalis. According to his scheme each train would carry its chemical lung in a carriage fitted either with a fan which would drive the air through tanks of lime-water, or with a system of gills in the shape of trays of slaked lime, through which the air would be made to pass with great rapidity. It appeared certain from calculations made that if each train were fitted in this manner, the whole of the air in the tunnel would be forced through the lungs and purified every twenty minutes. From a chemical and mechanical point of view the operation was sufficiently simple, while the cost of the lime that would be required was inconsiderable. His plan had been known to the directors of the railway for the last eighteen months, but various arguments were urged against its adoption, and, as everyone was aware, nothing of the kind had been attempted. The arrangements that he recommended for purifying the air in workshops and hospitals were similar in principle, but were less complicated and less expensive. Chemical punkahs, several of which had already been successfully tried, were so contrived as to bring the vitiated air into contact with a caustic solution of soda. The punkah itself, which is made of a vegetable fibre, is saturated with this mixture by means of a reservoir at the top of the fan, the weakness of the capillary attraction rendering necessary this method of saturation. There was no doubt, indeed, experience showed, that this apparatus was efficient and easily managed wherever scientific ventilation was impracticable. Examples of the chemical punkah were exhibited in the lecture-room, and a vote of thanks was accorded to the lecturer.

THE INSTITUTION OF CIVIL ENGINEERS.

THE sixty-third annual general meeting was held on Tuesday, the 20th of December, the president Mr. Abernethy, F.R.S.E., being in the chair. The notice convening the meeting having been read, and scrutineers of the ballot for the election of a council for the ensuing year having been appointed, the secretary read the annual report of the council upon the proceedings of the Institution during their period of office and upon its general condition.

It had been pointed out by Thomas Tredgold in 1828, when requested to define the nature and objects of civil engineering, that the domain of the civil engineer would extend with every discovery of science. A comparison of the papers contributed thirty years ago with those of the present day bore out this opinion, as it showed the great changes brought about in the interval in the practice of the profession by the new industrial applications of science. Having regard to the increasing number of subjects which occupied the attention of engineers, it was manifestly important that the papers read at the meetings of the Institution, and selected for publication, should be so varied as to be useful to its members in whatever branch of the profession they might be engaged. The tendency of modern manufacturing processes was to rely more and more upon machinery, the design and construction of which, as it became more elaborate, could no longer be the work of the mere handicraftsman, but called forth the highest powers of the skilled engineer. It thus happened that men were now to be found exercising engineering vocations widely different from those of the designers of roads, bridges, and similar public works, who, very erroneously, had often alone been recognised as civil engineers. As the Institution was largely composed of the former class, it was necessary that the range of subjects for papers should be widened, so that all interests might be consulted. The Council appealed to the four volumes of "Minutes of Proceedings" issued since the last annual meeting, as evidence of the success that had been attained in this direction.

A short synopsis was then given of the contents of the four volumes. It was stated that, besides Mr. Abernethy's address as president, which related mainly to the remarkable growth of dock and harbour accommodation for the commercial marine, fourteen papers had been read and discussed at the ordinary meetings, while thirty-seven other communications had been selected for printing, including six students' papers out of eighteen read at as many supplemental meetings. The combined articles ranged over most of the questions now occupying the attention of engineers. The foreign abstracts continued to be highly appreciated, especially by members resident in distant countries who were debarred from access to information respecting the progress of engineering on the Continent and in America.

During the past year there had been an increase of 52 members, 119 associate members, and 49 students, with a decrease of 16 associates, while the honorary members remained the same. There were on the books on the 30th of November last, 18 honorary members, 1,261 members, 1,406 associate members, 552 associates, 662 students; together, 3,899. At the same date in 1860, the number of members of all classes was exactly 1,000. The Student class had only been created fourteen years. In the interval, 1,462 candidates had been admitted, of whom 400 had since been elected into the Corporation, and 400 had ceased to belong to the Institution and in most instances to the profession. The deceases had been at the rate of 19 per 1,000, and had included several very old members, notably Mr. James Ashwell, the survivor of the five founders of the Institution.

The income last year was £12,393 11s. 5d., besides which the receipts had included £3,076 14s. on account of admission fees and i.e. compositions (which were rigidly treated as capital, and were not used for defraying ordinary expenses), and £431 5s. 6d. from dividends on trust funds. The general expenditure had amounted to £12,092 7s. 11d.

The President then presented the premiums and prizes to the respective recipients, and, in doing so, expressed his high sense of the obligations the general body of members were under to the authors of papers.

THE TOWERS AND STEEPLES OF WREN.*

THE steeples of Wren will always have an interest to the architect. Mr. Andrew T. Taylor, A.R.I.B.A., has brought out a little book under the above title, with illustrations and a descriptive and critical essay. The substance of the essay recently gained the Medal of the Institute, since which it has been revised and further illustrated. The sketches, plans, and sections given in the book have been made by the author on the spot, and though on a small scale, appear to be trustworthy and accurately drawn. Many of the steeples have been pulled down, and of these the author has obtained the best representations, chiefly from Mr. Clayton's valuable work on the subject. The critical essay prefixed to the book gives a rapid sketch of the evolution of towers, steeples, and spires, couched in rather high-flown language, tracing the history of the tower, from the Tower of Babel to the steeples of Wren. The merits of Wren's steeples are examined, their scientific construction pointed out, and the author refers to the care Wren bestowed on building his towers and steeples without the aid of iron tie-rods. Alluding to the merits of these steeples, Mr. Taylor remarks upon their proportions, that all Wren's towers would bear lanterns or spires without destroying their appearance, and that all the steeples with lead lanterns would bear the removal of the upper portions without detracting from the beauty of the towers. As architectural features these towers were never poised on roofs, or made to rise from behind porticos, but sprang from the ground in a plain and dignified manner, the upper stages only being varied in outline.

The steeples illustrated and described are classed into (1) those in London, existing and pulled down, and (2) those outside of London. The existing towers are divided into (1) stone

steeples, of which there are nine; (2) the timber and lead spires and lanterns; and (3) the towers (12 in number).

Plate I illustrates six of these steeples—St. Bride's, St. Mary-le-Bow, St. Vedast's, Fosterlane; Christ Church, Newgate-street; Campanile of St. Paul's, St. Dunstan-in-the-East. These are drawn as perspective sketches to a small scale. Describing St. Mary-le-Bow, Cheapside, Mr. Taylor says Wren, in sinking the foundations, came upon an old Roman causeway 4ft. thick, and on this the tower was built. The tower was begun in 1671, and finished in 1677, and cost £7,388, or nearly as much as the church. The author thinks the cylinder behind the beautiful peristyle might have been increased in diameter 3ft., which would have given greater solidity. A section of this steeple, as well as that of St. Bride, are given, showing the central spiral staircases. The campanili of St. Paul's are considered justly amongst the finest of Wren's compositions. St. Bride's steeple is carried on an ogee-shaped dome. Sections and plans of the other steeples are given, which will be found useful. St. Michael's, College-hill; St. Stephen's, Walbrook; St. James's, Giltick-hill; St. Mary Magdalene, complete the stone steeples illustrated. The second and third of these are compositions of much grace and beauty, and the sketches given of them are truthful. The lead spires and lanterns include the following illustrations:—St. Magnus, London-bridge; St. Margaret Pattens, St. Swithin, Cannon-street; St. Augustine and St. Faith, St. Anne and St. Agnes, St. Belet, St. Edmund-the-King, St. James, Westminster; St. Margaret, Lothbury; St. Lawrence Jewry, St. Martin, Ludgate-hill; St. Mary Abchurch, St. Mary Aldemary, St. Mary Bassishaw, St. Mildred, Bread-street; St. Nicholas, Fish-street; St. Stephen, Coleman-street; St. Peter, Cornhill. Of these, St. Magnus, London-bridge, is, perhaps, one of the best; but in many of the leaden lanterns we discern playful outline and picturesqueness. St. Augustine's, Watling-street; St. Martin's, Ludgate; St. James's, Westminster; St. Margaret, Lothbury; St. Mary Abchurch, and St. Mildred, Bread-street, are all unique compositions which serve to indicate the materials used in their upper part. We cannot mistake these lanterns for stone ones.

Several towers of much beauty appear. All Hallows, Lombard-street, is one of the plainest. In this part we find the tower of the gateway of Christ Church College, Oxford, a domical lantern termination in Late Gothic crowning Wolsey's tower. The Gothic towers of St. Alban, Wood-street, St. Mary Aldemary, St. Michael's, Cornhill, are characteristic, and some of them possess a dignity despite their detail. Mr. Taylor's little work is increased in interest and value by the sketches of the steeples and towers which have been pulled down. We are glad to find a correct sketch of St. Antholin's, Watling-street, a stone spire of much simplicity and character. The critical remarks appended to some of the descriptions are just, though we are inclined to disagree with the author sometimes. The translation of the Gothic types into Classic forms was one of the remarkable instances of Wren's power, as pointed out in describing St. Margaret Pattens; but St. Antholin is even a better illustration of this. In conclusion, the author pleads for the preservation of the steeples of Wren, and it is saying a good deal when we hear of so decided a Gothist as Mr. Street advocating the same cause. Mr. Taylor's book is neatly printed and got up by B. T. Batsford, and we commend it to every one who takes an interest in the history of our English Renaissance, and who requires a compendious handbook to the steeples of England's greatest architect. As a record of many of the towers which have been taken down, and of others which are likely to disappear in a few years, the work has a special value to all antiquaries.

LONDON MARKETS.

THE new market at Leadenhall was opened last week. It has been designed by the City Architect and—so a City contemporary says—his "powers of design are very well displayed in this his latest achievement." Entrance is obtained from Gracechurch-street, through a gateway, a handsome and substantial structure, with two wings. An area between 26,000 and

27,000ft. has been built over and covered in to form the market, to which there is at present access by roadways 30ft. wide from Gracechurch-street on the west and from Leadenhall-street on the north. A new street, which will give an approach from Lime-street, is nearly finished, and it is proposed to make another new street from the end of the south arcade to Fenchurch-street. The principal arcade, running east and west, is about 290ft. long and has a width of 30ft. throughout. The shops on either side are of two storeys above the ground floor, and have cellars. These shops have a frontage of about 16ft. each and they extend back from 16ft. to 35ft. As now divided, there are 31 shops let to retail and wholesale dealers, all the old tenants, it is said, except some of the live-stock dealers, having had accommodation provided, and at rents below the value of the land for commercial purposes. The land to the north-west, at the corner of Gracechurch and Leadenhall streets, a part of the old Hide Market, has been let on lease, and offices and shops will be built upon it. A double system of drains has been provided in the new market, the upper to carry off surface water. The market has been erected by Messrs. Nightingale, at a cost of nearly £50,000. The shutters and fittings in connection therewith for the shops were supplied by Messrs. Francis and Co., 174, Gray's-Inn-road.

Encouraged by the success of their fruit and vegetable market at Stratford, the Great Eastern Railway Company are now constructing an extensive fish, fruit, and vegetable market underneath their new goods depot at Bishopsgate, formerly their passenger terminus. The area set apart for the purpose is about 4½ acres. Three lines of rails will be laid down the centre of the plot, to which trucks will be lowered by hydraulic hoists from the goods station above. On the north will be a row of 33 warehouses for fish, and on the south 16 large warehouses for fruit and vegetables, each having a cellar beneath and offices, and other trade conveniences on the rail level. The fruit and vegetable warehouses will also be provided with a "dock" or siding, which will accommodate one, two or three trucks, according to the extent of its area, and there will be a line of rails running the whole length of the exterior of the market, communicating by two sidings with the three centre rails. Each row of warehouses will have a covered roadway along the whole front protecting the loading of carts and wagons during inclement weather. The market will have four entrances, two from Brick-lane, one from Bethnal-green-road, and one from Norton Folgate. The market and approaches will be illuminated by the electric light, and will be open at night for retail trade, as well as in the morning and during the whole of the day for wholesale business. Part of the market is expected to be ready in three, and the whole to be completed in six months.

WHAT IS THE CAUSE OF PLUGS OR PUTTY-HOLES SHOWING?

AS for the above, says the *American Carriage Monthly*, there are a great many answers given. Almost every painter you ask will give you a different reason, while the majority of them will tell you when the plugs show that it is the fault of the body-maker in not putting them in right, and the body-maker will tell you that it is the painter's fault, and so it goes.

We have heard some men tell us the way they overcame this difficulty of keeping the plugs from showing, which is to avoid putting any glue in the hole; glue the edges of the plug only, and as you drive it in, avoid coming in contact with the head of the screw, because if you let it touch the screw the wood is temporarily upset, and as it seeks its natural condition, and being free to expand but one way because of the screw head back, they are bound to come beyond the panel on the outside surface, but if they are not driven back upon the screw-head it will be more than likely, instead of showing on the outer surface, to go the other way, which would prevent it from showing.

Be this true or not, we cannot tell; but there is one thing certain, they show, and the painter cannot stop this, and therefore should not be to blame. There are very few places where there are plugs put in that they do not show, and

* The Towers and Steeples designed by Sir Christopher Wren, &c. With numerous illustrations. By Andrew T. Taylor, A.R.I.B.A., Architect. London: B. T. Batsford, High Holborn.

how to remedy it, so far as the painter is concerned, will remain a mystery.

In putting nail-holes or screw-heads, we do not favour the plan of most body-makers putting the brads or screws in as deep as they can get them without going clear through the panel, as it is very hard to get the lead colour in these deep holes. But where this is the case, we must do the best we can with the priming and leading. We must get in the holes all we can, and as far as we can, and then take some hard drying putty and fill the holes about half full, and when this is dry fill up the rest of the holes. This putty, we think, is the best, because it dries firmer and harder, and there is not so much danger of shrinkage as there is in putty made of whiting. The first putting in a deep hole cannot dry as quick as the outer part, on account of the air not getting to it so well. If you should putty them full with the one puttying, there will invariably be trouble with shrinking or swelling of the putty. Some painters do not use putty for brad-holes, but fill them up with paint and filling. Should there be any places that are not entirely filled up after the body is rubbed down they then use the putty. We have no experience in this way of working, but give it as one of the methods described to us.

We have seen brads and screws where they have been put in level with the surface or a little below, after being puttied and painted, and no trace of them could be found, and sometimes remained hid a great deal longer time than some that are put in deep; but of this you cannot convince the woodworker or get him to acknowledge any of the theories presented on this question.

Now we have seen the brad level with the panel and no putty used, and yet show as if it had been puttied, and the putty swollen out. This, we think, is caused by not having thoroughly seasoned wood, and is occasioned by the shrinking of the panel. Some painters imagine the putty is more inclined to show by the wood swelling than by its shrinking, because, as they say, in driving a brad or nail into the wood, the wood being pressed away to make room for the nail, the damp weather will swell the wood around the nail, and thus force the putty out. We have noticed the swellings do not look the same at all times—sometimes very bad, and again hardly visible to the eye. Whether dampness causes this, we are unable to say, but are inclined to think it has somewhat to do with it.

The only thing we can do is to use thoroughly seasoned lumber, have the woodworker to drive the nail or put the screw in so as to require the least amount of putty, and then for the painter to let the putty as well as the paint have time to dry. We have seen painters putty a job, and a few hours afterwards give a coat of paint, so that he may finish the puttying the next day; now it has been puttied twice before the first has had time to dry, and consequently will show every place where there is a nail or screw, because no precautions have been used against it.

PRACTICAL NOTES ON PLUMBING.—XXII.*

By P. J. DAVIES, H.M.A.S.P., &c.

(Continued from page 753.)

INSIDE WORK, OR SANITARY PLUMBING, CLOSET, &c.
FIG. 123.

THIS diagram illustrates a valve-closet, fixed over the half S-trap (wrongly designated a U-trap). This kind of closet, above all others, *must* be fixed over this kind of trap, as the momentum of the water in passing from the valve of the closet entirely destroys the water-seal of the trap, which necessarily renders the trap totally useless. Under all such closets, a properly constructed S-trap is the only one at present invented that will prove thoroughly efficacious.

This closet, like all others, should have an ample supply of water, so that every part of the basin may be thoroughly washed, more especially the front part. A very excellent method for testing the efficacy of the water flushing is to dry the basin by partially opening the closet-valve, and then painting the basin all over with a good coat of plumber's soil; then in the ordi-

nary manner pull up the handle of the closet, and if any part of the basin is not cleansed, the flushing is not perfect.

In order to avoid such a contingency, it is necessary, first of all, to have a properly-sized

pipe and valve, and by all means do not make any very sharp bends or a lot of branches. When you are so circumstanced that you are compelled to have branch joints, you should always make them at the easiest possible angle.

By adhering to the following instructions (which will, in most cases, be found a very good workable table), a very effectual flush may be relied upon for a closet supply. When the head of water is 5ft., use a 1 1/2 in. full-way valve with the same-sized pipe; but when the pipe has to be taken in a horizontal direction, in all cases use the next size larger to allow for friction. When the head of water is between 5ft. and 15ft., use 1 1/2 in. full-way valve and pipe; though if the pipe runs from 7ft. horizontal, use 1 1/2 in. pipe to allow for friction. Again, should the head of water be from between 15ft. and 40ft., use a 1 in. valve; and, in my opinion, nothing less than a 1 in. valve should be used, although in cases from 40ft. to 60ft., a 1 in. pipe may be used; but larger, according to whatever length of horizontal pipe there may be. Perfect flushing also depends, to a very great extent, upon the kind of closet-basin used.

In my estimation, Sharp's pattern, known as the flushing rim, is the best. In using this basin, care should be taken to prevent any dirt or other foreign matter getting into the rim, as it will prevent the water passing all over the basin, and consequently leave it only partially cleansed.

CLOSET-PIPE STOP-COCKS.

When selecting stop-cocks to be used on pipes in connection with closets, great care should be taken to select only those having a straight full-way, known as a "round-way,

In cases where it is compulsory to use valve-cocks, always select them with straight ways, similar to that shown at Fig. 132.

On reference to Fig. 133, it will be easily observed that the seating B is so constructed

that the water is greatly retarded in its progress for these reasons:—It first strikes against the partition W, and rebounds from there to the bottom Z, from Z to S, thence from S through the seating B, and up against T, back to V, from V to X, and finally onward along E. Now

this diagram and explanation shows distinctly that the water has to take no less than six different sharp curves before it can pass out of the stop-valve or cock; and, curious as it may seem, the shell and seating of this stop-valve

* All rights reserved.

ground-in stop-cock," shown at Figs. 130 and 131.

is the one generally adopted by our water companies.

Farther on I shall give the full particulars of a practical test of the loss of head-water by the use of such stop-valves.

Fig. 134 is an elevation of the last-named stop-valve, showing the stuffing, cap, the squares on the tap, and the tinced ends; A the inlet, and B the outlet. Fig. 135 is another kind of stop-valve, made without the stuffing-box, but having an indiarubber diaphragm at C to answer the same purpose. The water-way is much the same as in Fig. 133.

(To be continued)

THE NEW CATHEDRAL AT TRURO.

THESE works, as most of our readers are aware, have been carried on up to the present time by Mr. Pearson's trusty clerk of works, Mr. James Bubb. Under the immediate direction of this genial and efficient craftsman, a large staff have been for some time at work. They have pulled down the neighbouring houses, and entirely removed the old church of St. Mary, with the exception of its south-east end, and have put in the foundations of the choir and built the crypt. The works being thus far advanced, it has been deemed well to secure a trustworthy and tried contractor to carry out the actual building. This has been satisfactorily arranged, and on Monday, December 19th, Mr. Shillitoe (late of the firm of Shillitoe and Morgan, of Doncaster) commenced his contract for building the choir. Mr. Shillitoe has already built some of Mr. Pearson's best churches, and so is by no means an untried man. Mr. Bubb, of course, continues as clerk of works, to fulfil the duties he has so faithfully carried out heretofore. We hear that his connection with Mr. Pearson extends over quarter of a century.

IRISH BUILDING-STONES.

MR. G. PHILLIPS BEVAN, in speaking of the industrial resources of Ireland, before the London Statistical Society, on Tuesday evening, said that many of the building-stones of Ireland are equal to the best in Great Britain. Professor Hull, of the Irish Geological Survey, than whom no better authority exists, states that the Donegal red granite is equal in beauty to that of Peterhead, and capable of receiving a high polish; while those of Wicklow and Down are of a greyish tint, and are extensively quarried at Kingstown, Newry, and Castletellan. There is scarcely any country in the world which, for its size, possesses greater variety of building marbles of all colours. At Kilkenny and in the quarries of Galway there is black marble to any extent, while the latter county yields also white marble, absolutely pure in tint, and, as far as quality goes, of the strongest kind of limestone. Red, yellow, and blue marbles are found in the county of Armagh, purple and white, and blue and white at Churchtown (county Cork), ash-coloured, grey, and dove-coloured at Carrigaline and Castlemartyr (county Cork); variegated near Tralee; sienna near Shannon Harbour, on the Galway side; fine grey in King's County, and Tipperary; striped white and red at Killarney; and brownish-red at Ballymahon (county Longford). Then again, in Galway and Mayo, are quarries of serpentine of the most valuable kind. A recent letter in *The Times* calls attention to the fact, that while the red, green, and black marbles of Ireland are largely used, green Irish porphyry is scarcely known; and also that some of the green marbles are of the most lovely colour and quality imaginable, looking like dark green seaweed beneath the clear sea. And yet even Irishmen are oblivious of the rock-treasures that lie at their very doors—as witness, for instance, the splendid mansion of Castle Coole, near Enniskillen, built of freestone brought over from Bath at a fabulous price, though marble of the first quality was to be had for nothing. The slates from Killaloe and Valentia Island are well known and appreciated, as are also those of the Clanwilliam Slate Company at Wooden Bridge, county Wicklow; but there are many other places in which slates are known to exist, even though they are not of such first-rate quality as to compete with North Wales. Sir R. Kane mentions such at Clonakilty and the Old Head of Kinsale; at Westport, in

Mayo; and at Ross, in Waterford. And yet, according to Dr. Neilson Hancock, writing in 1864, the streets of Dublin are paved with Welsh paving-stones, and the houses slated with Welsh slates, which, it may be naturally assumed, were preferred because they were better. Judging, however, from the character which the quality of the Irish slates have attained in the market, it seems more likely that that the real stumbling-block is that of expense, caused by one of Ireland's chief difficulties—viz., the lack of communication and means of transport.

BOOKS RECEIVED.

Sketch of the Life and Labours of Mr. Alderman John Guest, F.R.S., of Rotherham, by THOMAS BEGGS (London: Simpkin, Marshall and Co.), is a life written by an intimate friend, of a man who did a good deal in his time, in conjunction with others, for sanitary science. The details given in this volume, however, are for the most part of a personal character, and will probably interest many who knew the subject of the memoir better than in his business life.—*The Royal Indian Engineering College, Cooper's Hill, Calendar for 1882* (London: W. H. Allen and Co.), is an official almanac and guide to the course of study at the college, by whose authority it is published.—*Calvert's Mechanic's Almanac and Workshop Companion for 1882* (Manchester: John Calvert), is published for the ninth time. It is as complete and cheap a publication of its kind as we have ever seen, full of information and worth many times its cost to every intelligent workman and amateur.—Messrs. Hudson and Hearn, of 83, Southwark-street, have sent us some copies of their *Diaries and Date Indicating Blotting-Pad Diaries*. The distinctive feature of these diaries is their comprehensiveness, each volume forming in itself a complete set of books indexed and paged throughout. No. 12 and 13 are specially arranged for the use of architects and surveyors, but are most useful for all professional or business purposes; they contain not only a diary which is virtually a day-book or journal, but a cash-book, ledger, and note-book, rent, and insurance registers, and the paper and binding are of unusual excellence. No. 11 is specially adapted to the requirements of those in the building trades, and contains a series of tables of a practical rather than of a scientific character, including the calculation of wages, the checking of estimates, &c. In all these diaries the index is a valuable feature. The "Date Indicating Blotting-Pad Diaries" we consider particularly useful, and know that they have been very well received. They are this year indexed, and there are also added a few pages for entering cash received and paid, both valuable additions.—*Letts's Diaries*, 1882, of which we have received some specimens, are as useful and numerous as ever. There are, we are told, over 307 bound books, and a further 200 varieties in Russia, Morocco, silk, &c., for presents in endless varieties of form, size, or price. Messrs. Letts publish a very clear and intelligible list, which can be obtained on application either direct to themselves at London-bridge or from the nearest stationer's or railway station.—A capital Card Almanac is also issued by Messrs. Steven Brothers and Co., of Upper Thames-street, well known to most of our readers as the owners of the largest iron foundry in Glasgow, which covers over seven acres and employs over 1,000 men.—Messrs. T. J. Smith, Son, and Co., of 83 and 84, Queen-street, Cheap-side, and 13 and 14, Pancras-lane, have also sent us some specimen Diaries for 1882 of a handy and useful character.—*Suffolk Directory and Almanac*, 1882, by John Glyde, Ipswich, is well got up and carefully compiled.

FLEXIBILITY OF MARBLE.

ELASTICITY is a general property of matter, but its manifestations are very variable according to the form of bodies and the nature of the stress exerted. Thus, a crystal ball will rebound to a great height from a pavement, and a thread of glass has all the flexibility of silk; but that does not prevent us from commonly saying, "As fragile as glass," because of the common accidents that we see in daily usage. The rigidity of marble has served as a

subject from the remotest times for the metaphors of all poets; and I do not know that a single architect has ever foreseen that a slab of stone might bend and act like a fir plank without flying into fragments. This, however, is something that may at present be seen at the palace of the Alhambra, at Granada, as one detail lost among the thousands of wonders of that enchanting maze. One of the two doors that have been christened "La Mezquita" (probably because near by there is an old unfinished chapel of the time of Philip V.) exhibits an ancient facing of three slabs of marble, the upper resting as a lintel upon the two others, which form uprights 11ft. in height, 9in. in width, and only 2½in. thick. If we compare this door with that to the left, we at once remark that it is much smaller, having been diminished on every side, not only by the thickness of the white marble, but also by a thick layer of plaster beginning at the point where the old facing of tiles is set in.

Now, whoever has had an opportunity of admiring the mathematical precision of Arabic structure cannot possibly doubt that all this has evidently been added too late to remedy a subsidence, of which evidence is still to be seen in several cracks in the upper wall. But nothing resists certain stresses, and an enormous thrust upon the right must have been the sudden cause of the rising of this side as well as that of the upper slab. How comes it, then, that the marble, instead of breaking or of rupturing its casings, has simply bent and curved as if it were wood? How comes it that it has been able to remain thus, like a bent bow, from an epoch which is totally indeterminate, but which, it is quite likely, dates back to the explosion of a powder-mill on the other side of the Darro, which, in 1590, destroyed a large portion of Mezcuar? What is certain is, that the propwork of joists now to be seen was put up only at quite a recent date, and during the course of the restorations so fortunately undertaken, some few years ago, to bring to light that graceful stucco lacework and those superb mosaics of faience, and all those masterpieces of profane art which Christianity had so piously buried under thick layers of plaster of Paris. The setting of vitrified bricks, moreover, was found completely destroyed up to about 12in. from the top of the door; and it is exactly at 18½in. that the slab begins to curve and to detach itself from the wall, to attain its greatest distance therefrom of 3in. at about 3ft. from the bottom.

We may ask what would happen if, by any means whatever, the stone bow should be unbent, or one of its extremities be set free and given play, or the other be unloaded of the weight which holds it in place? Would the stone be seen to straighten back like a spring, or would it remain permanently misshapened? Or, indeed, would it break in pieces on escaping from the slow and gradual cause which alone has produced in it so singular an effect? Might not there be found in the molecular homogeneity to which it has evidently owed its resistance to fracture, curious crystalline modifications like those produced artificially by Mr. Walter Spring by means of great pressure? Unfortunately, we can only place here a series of interrogation points, and we shall esteem ourselves fortunate if some interested reader down there will keep us informed as to anything new that may happen.—*La Nature*.

GLASGOW PHILOSOPHICAL SOCIETY.

THE following awards, among others, have been made by the Glasgow Philosophical Society, in connection with the recent Gas Exhibition:—

VENTILATING AND SANITARY APPLIANCES, &c.

Jurors.—Professor James Thompson; Mr. John Horveman, I.A., F.R.I.B.A.; Mr. A. Lindsay Miller; Mr. H. K. Bromhead, I.A., A.R.I.B.A., convener.

Medal.—William Paton Buchan, Glasgow, for Buchan's cascade-action ventilating tap for drains. Messrs. J. & M. Craig, Kilmarnock, makers; William Paton Buchan Glasgow, for Buchan's "Carmichael" wash-down accessible water-closet.

Honourable Mention.—James Combe and Son, for washing apparatus for public wash houses; Faraday and Son, London, for ventilating gas pendant; British Sanitary Co., Glasgow, for earth closet; J. and M. Craig, Kilmarnock, for white enameled sinks and wash-tubs.

ELY CATHEDRAL TOWER AND CHAPEL OF THE COLLEGE.—SOUTHWELL MINSTER, AS RESTORED BY J. W. H. CHRISTIAN.—CENTRAL INSTITUTION OF THE CITY AND GUILDS OF LONDON INSTITUTE.—ANCIENT SEPULCHRAL MONUMENTS.—NEW INFIRMARY AT CARLISLE.—NEW CHURCH OF ST. GERMAN'S, CARLISLE.—STAINED GLASS: SCENES FROM "THE MERRY WIVES OF WINDSOR" AND "AS YOU LIKE IT."

OUR LITHOGRAPHIC ILLUSTRATIONS.

ELY CATHEDRAL TOWER.

THE interest attaching to this drawing would perhaps be more properly ascribed to picturesqueness of grouping than any special merit displayed in its several features. It is taken from a point adjoining the college grounds looking on the south front of the great west tower, with the Grammar School Chapel and other buildings in the foreground. The tower itself (at least the upper part) can hardly rank as a good example of even a declining period, as though the masses are well arranged to appear advantageously at a distance, the detail is disappointing; neither can the other surroundings embraced in the drawing lay much claim to architectural significance. But, taken as a whole, its charms are incontestable; and given a fair day and broad shadows, as I was favoured with, a lover of the art must acknowledge the spell at once, and will scarcely rest a moment till his pencil has paid tribute to its beauty. Every accessory about that art or nature can provide will be found; with gables and dormers, turrets and tower, "mantling ivy" and foliage interspersed—all blending and mellowed by the tints of time and hallowed by the sacredness of association for centuries past. If the emotional is not always to be subordinated in this practical, competitive age, here at least its softening influences might be permitted a little latitude.

Meanwhile the bees are chanting a low hymn;
As fluttered by the wings of cherubim,
And, lost to sight, the estate link above
Sings like a soul to itself of love.

Chronologically considered, the chief epochs connected with the edifice are too well known to need recapitulation here. But the tower, which forms the centre of interest, is the work of two distinct periods. The earlier by Bishop Rickh, between the years 1171 and 1189 Anglo-Norman; the latter by Prior Walsingham, commenced 1521 and completed 1543. The former square tower, which was originally placed at the intersection of the nave and transept, is recorded to have fallen in the year 1320, but rebuilt by the same architect in the form of an octagon, with lantern over; the wooden construction now completing it, and covered with lead, being a much later importation of a thoroughly debased type. It is only a few years since the western tower also gave signs of weakness, and an evident tendency to follow its predecessor, in consequence of which the late Sir Gilbert Scott was engaged to strengthen it, cramping and bracing the whole structure together by a system of iron ties; and we may fairly hope it has now entered on a new lease to

adorn for many ages the venerable and beautiful fabric over which it so conspicuously reigns.—J. D.

CENTRAL INSTITUTION FOR THE CITY AND GUILDS OF LONDON INSTITUTE FOR THE ADVANCEMENT OF TECHNICAL EDUCATION, SOUTH KENSINGTON.

THE great advances made of late years in the law of technical education abroad and its attendant good results in the way of increased manufacturing prosperity, have induced many thoughtful persons in this country to turn their attention in this direction—not surely before it was needed. None appear to have done so to more purpose than certain influential members of some of the City Guilds, who have combined together to do what in them lies to remove the stigma of indifference to scientific education on the part of our manufacturing population, by inducing their Guilds to establish certain schools and endow others. Their greatest concentrated effort will be seen in the building which we illustrate this week, and which they have confided to the care of Mr. Alfred Waterhouse, A.R.A. The "foundation-stone" or memorial column of this building was laid by H.R.H. the Prince of Wales, surrounded by a distinguished company in July last, in Exhibition-road, South Kensington. The foundations have been already put in by Messrs. George Munday and Sons, and the contract for the superstructure having been competed for, is likely to be confided to Mr. H. Lovatt, of Wolverhampton. The building will consist of a front of 300ft. in length, of five stories in height, averaging 15ft. 9in. from floor to floor so far as regards all but the topmost, which will be of varying heights, the central room and the two rooms at the extremities of the building being much higher than the rest. The north-west corner at the back is only four stories in height, consequent on the greater height of the lecture-rooms penetrating the first floor. As it is not known how far light can be commanded on the north and south sides of the plot, it has been decided, with the exception of the two front end gables, which, of course, derive their light from the east, towards Exhibition-road, to set the building back 20ft. from the boundary north and south. On the western side the building comes right up to the boundary along its entire length. Should the Institution ever be extended beyond the bounds of the present site, these areas on the north and south might possibly be widened to 40ft., and so give excellent internal courts for light and ventilation. A corridor 10ft. wide runs right through the building from north to south, and there is a cross corridor 7ft. wide in the return portion of the building on the north. All the space at the back behind the main corridor (with the exception of the lecture-room wing on the north) is left for the present unoccupied, save by workshops under glass roofs at the basement floor level extending over a portion of the space. This main corridor is lighted by large windows at either end, and by a range of windows on either side of the main staircase on the ground-floor and upwards, and also by the windows themselves. The main staircase, which rises by a double flight immediately opposite the principal entrance lights by its numerous windows the centre of the building. The entrance is in the centre of the main front, the ground-floor level being approached by about ten steps from Exhibition-road through a large and handsome hall, 37ft. by 33ft. 6in., the groined ceiling of which is supported by four piers, the inner ones being of granite. It was one of these which formed the memorial-stone before alluded to. In order to facilitate communication between the different floors, two subsidiary staircases are placed on the west side of the main corridor towards its extremities, and have lifts in their immediate proximity. The requirements which were originally decided upon, though they were, doubtless, not exhaustive, involved a superficial area of 11,000 square feet of floor-space, not including corridors, &c. The plans contain accommodation under the following heads:—Mechanics—Nine workshops or classrooms; three sheds with glass roofs; mathematical classroom. Physics—Thirteen class-rooms, &c. Art—Seven class-rooms, &c. Chemistry—Six vented laboratories, classrooms, special laboratories, and private rooms. Metallurgy—One workshop. Council chamber and six other rooms for the administrations; two unappropriated rooms; two lecture theatres, each holding upwards of

200 students, with preparation rooms adjoining. Students' rooms—Reading-room and library, refreshment room and lockers; housekeeper and porter; engine-room and heating apparatus; coals and wood; lavatories, w.c.'s, &c. Behind the centre of the building are three glass-roofed sheds, which can be divided at pleasure, and will be adapted for processes which might give rise to annoyance if within the walls of the main building. There are so placed as to leave the space, 78ft. by 66ft., above mentioned, entirely clear for an additional wing. On the first floor, in the centre, is the council chamber, a handsome room, 37ft. by 33ft. To the right are five rooms devoted to the administration, with two rooms on the opposite side of the corridor unappropriated, the students' library and reading-room being at the north-east corner of the building. To the left are four rooms devoted to Physics. The upper part of the lecture-rooms occupy the rest of the first floor, and the corridor between them will be of use in gaining access to the upper seats. On the second floor are placed seven rooms devoted to Art in its various branches, whilst the whole of the north end of the building on this floor is given to Chemistry, there being two large chemical classrooms, with a photographic room in the centre, two private rooms behind them, and four rooms to the front. The front and returns up to the north and south areas are proposed to be faced with red brick and terra-cotta. The chief merely ornamental features of the front will be the arms of the City of London, and of the various Guilds the benefactors of the building, which are up to the present time as follows:—(1) Mercers, (4) Goldsmiths, (18) Plasterers, (7) Ironmongers, (15) Carpenters, (9) Clothworkers, (6) Silvers, (2) Drapers, (7) Coopers, (13) Armourers and Braziers, (19) Needle-makers, (10) Dyers, (3) Fishmongers, (12) Pewterers, (21) Wheelwrights, (16) Cordwainers, (11) Leather-sellers, (5) Skinners, (8) Vintners, (14) Bakers, (20) Plumbers.

ANCIENT SEPULCHRAL MONUMENTS.

THE double-page plate of monuments we give is selected by us from proofs of plates for a new work on "Ancient Sepulchral Monuments" by Mr. Brindley and Mr. W. S. Weatherley, architect. The work, intended to be a text-book on the subject, will consist of 200 plates imperial quarto (half of which are, we believe, already printed), containing between 500 and 600 examples of all styles from various countries, from the earliest period to the close of the last century, comprehending head-stones, tombs, crosses, obelisks, incised slabs, wall-tablets, &c. Some 50 plates are reserved, we understand, for Gothic examples. Although the plates we give are somewhat elaborate, the purport of the work would seem to be chiefly simple monuments as suggestions in design for our everyday requirements. We may mention as a great merit of the work that the drawings are, as far as possible, to the uniform scale of 1in. to the foot, with details one-fourth real size. Great care has been exercised in the collection of accurate material, and in the choice of suitable specimens. The plates are drawn by Mr. Weatherley, who illustrated and edited Sir Gilbert Scott's "Royal Academy Lectures." The work is being printed by Messrs. Vincent Brooks, Day, and Son.

THE NEW GLAMORGAN AND MONMOUTHSHIRE INFIRMARY AND DISPENSARY, CARLISLE.

THIS building is intended to replace an old structure erected for a similar purpose about 35 years ago by the munificence of Mr. Daniel Jones, of Beaupré. The site has roads on north, south, and western sides, from the latter of which the administrative block will be entered. A corridor extends eastward from this block, from which the ward blocks will branch alternately north and south. There will be accommodation for 102 beds by the present contract, and allowance for future extension to a similar number has been arranged. The wards will be warmed with the Thermodyne grates, and the latest improvements for the admission of fresh air and the extraction of foul air will be applied. The architects are Messrs. James, Seward, and Thomas, of Cardiff, and tenders are now being invited for its erection, which will be commenced early in the new year.

SOUTHWELL MINSTER.

THE repair of the Collegiate Church at Southwell, so far as regards the walls, has been in progress for many years past, and the building in that respect has been restored to sound condition. But in the year 1873, when by lapse of time the old arrangements of the chapter ceased to exist, it was thought well, before handing it over as a parish-church, that everything necessary or desirable to be done to put the whole structure into seemly and durable condition, should be at once undertaken, and Mr. Christian was instructed to survey and report accordingly. The church had greatly suffered in the first place by the fire, which in the year 1711 consumed the ancient roofs, and, secondly, by the removal in the year 1802 of the lead-covered spires, which up to that time had terminated the western towers. The chapter-house, also, had been denuded of its conical roof. The modern roofs, substituted for the ancient ones, were all of inferior material and workmanship, and covered with slate. As regards the nave and transepts, this was no doubt the consequence of enforced economy, but in respect of the spires and conical roof of the chapter-house there must needs have been a considerable gain from the sale of the lead. Mr. Christian advised that the roofs of the nave and transepts should be restored on the old lines, of which the central tower gave indisputable evidence, and that the roof of the chapter-house, and the western spires should be also restored, and this advice was adopted and has been followed throughout. The new roofs and spires have all been reconstructed with very substantial timbers of English oak, and covered throughout with cast lead on a double thickness of boarding. In designing the spires, every possible care was taken to ascertain as nearly as possible the ancient outlines, as to which a considerable amount of evidence was obtained by a comparison of old prints and documents relating to the building. Also before the work was actually commenced, Mr. Christian was fortunate enough to secure an original and evidently very accurate water-colour drawing, believed to be by Turner, probably made only a very short time before the spires were removed. The exact point from which this view was taken was easily ascertained, and it is believed that in respect of height, leading, &c., the restored spires must very closely resemble the ancient ones, and whatever differences of opinion there may have been as to the propriety of attempting the restoration, there can be little doubt now but that the right course has been adopted. The only roof that has not been touched is that of the choir; but as there was not the same necessity for renewing this, the whole choir being groined in stone, it has been left for a future generation. Neither has any change been made in the covering of the central tower, respecting which there is no evidence to show that any spire ever existed. The removed roofs were flat-ceiled. Those of the nave and transepts are now open to the rafters, and the additional height thus gained is deemed to be of considerable advantage to the effect of the interior. Other works, including the re-fitting of the choir, the restoration to the ancient levels of the 13th-century chapels on the east side of the north transept, the general re-flooring, &c., will shortly be proceeded with, but up to the present time these have not been finally contracted for. In the flooring of the nave it is intended to preserve exactly the ancient lines, and as many as possible of the old stones, only making the necessary provision against damp.

SUBJECTS IN STAINED GLASS BY H. W. LONSDALE.

"MERRY WIVES OF Windsor." These panels form the upper portion of the dining-room windows at Beech Cottage, Allerton, recently enlarged for Mr. J. E. Rogerson, by Messrs. Aldridge and Deacon, architects, Liverpool. The first subject illustrates the scene in Act I., where Anne Page invites the reluctant Master Slender to enter the house and join the rest of her father's guests. The two centre panels represent the scene which we are to suppose is taking place in Page's dining-room during the foregoing conversation, Justice Shallow and Pastor Evans, entering shortly after the others, are welcomed by the master of the house. In the fourth panel, a serving-man is carrying up the

promised venison-pastry, while a maid goes to the cellar to draw the wine wherewith the company is "to drink down all unkindness."—"As You Like It." The subjects for the upper lights of the drawing-room windows at Beech Cottage are furnished by Act II., Scene 7, of this play. The four panels illustrate the incident of Orlando introducing his old servant Adam to the Duke, who, with Jacques, Amiens, and other followers, are living in banishment in the Forest of Arden. A fifth panel, completing the series, with Rosalind, Celia, and Touchstone wandering in another part of the forest, will be given in an early number of the BUILDING NEWS. The glass was executed by Messrs. Heaton, Butler, and Bayne, from cartoons by Mr. H. W. Lonsdale.

COMPETITIONS.

BLACKFRIARS-BRIDGE SCULPTURE COMPETITION.—Early in the present year, some fifty designs were submitted for the first of the groups intended to be erected on the four pedestals of Blackfriars-bridge, and, at the time (April 1st), we gave a review of the models contributed. At the last sitting of the Court of Council of the City of London, the award of Sir Frederick Leighton, P.R.A., the referee who has adjudicated on the designs, was read, though the final award has not yet been actually determined upon. Sir Frederick Leighton, it is stated, has selected six designs which he has grouped in three divisions. In group A, No. 11 is placed first, the subject being the "Triumph of the City of London," representing Britannia drawn in a car of rich design by lions, driven by a boy, the whole composition being good, if not strikingly original. Mr. Fabbrucci is the author. The second in group A is No. 22, "Queen Boadicea," we believe the design of Mr. W. S. Firth, of the Lambeth School of Art. Group B, No. 3, "India visits Britain," and No. 9 "Progress"; Group C, No. 19, "Queen Elizabeth"; and Nos. 43 and 44 "Memorial of the World." This selection has, we learn, been referred to the committee for further consideration. More than nine months have already elapsed since the designs were received, further delay, therefore, should hardly be necessary. All the premiated designs will become the property of the Corporation. The prizes are two of £250, two of £150, and two of £100.

EXETER.—Professor T. Hayter Lewis, F.S.A., was appointed last week by the Town Council of Exeter as official assessor in the open competition for the proposed new asylum at a fee of 100 guineas. The town council decided on Professor Lewis's recommendation that the competition be initiated by inviting preliminary sketches and ground plans, and that the committee, with the advice of the assessor, then select a certain number, not less than six or more than ten, for the final competition.

St. PANCRA'S WORKHOUSE.—At a special meeting on Monday last, the St. Pancras guardians selected the following five architects for a limited competition for the extension of the workhouse buildings—viz., Mr. Elijah Hoole, Messrs. Young and Hall, Messrs. J. Saville and Sons, Messrs. Wilson and Aldwinkle, and Mr. Bridgman. The gentlemen who were nominated, but not chosen, were:—Mr. R. Norman Shaw, Messrs. Isaacs and Florence, Messrs. Giles and Gough, Mr. Verity, Mr. John S. Quilter, Mr. Gaudry, Mr. J. P. Seddon, Mr. Waldron, Mr. Davids, and Mr. Young. It is proposed to divide £300 amongst four of the five competitors, and to give the work to the fifth. This arrangement, however, has to be confirmed by the Local Government Board before it can be carried out.

THE VICTOR EMMANUEL MONUMENT.—On Friday the exhibition of plans for the Victor Emmanuel monument at Rome was opened by the King and Queen of Italy. The models and drawings sent by the competitors of all nations occupy three stories of an extensive building in the Via Santa Susanna. Several artists propose to utilise the ruins of the Baths of Diocletian and the church of Santa Maria degli Angeli, built by Michel Angelo out of some of the halls of that ruin. Others project terraced gardens with colonnades and a colossal statue on the Janiculum Hill. Others again giving a utilitarian turn to the national gratitude, would have a monumental bridge on the site of the ancient Pons Sublicus.

TIDES AND TIDAL SCOUR.

AT the 13th meeting of the session of the Liverpool Engineering Society, held recently, the second part of the paper on "Tides and Tidal Scour," by Mr. Joseph Boulton, was read by the author. In the discussion which followed the paper, Mr. A. G. Lyster observed that the two chief instances of the formation of bars occur (1) in the case of rivers highly charged with detritus, which is held in suspension so long as the velocity of the river is maintained within its natural channel, but which becomes deposited when the force of the stream is dissipated by the waters of the ocean and the opposing action of its waves; (2) where the tendency of prevailing winds is to sand up the mouth of a river, which again works for itself a passage through the opposing barrier, and eventually brings about a balance of forces which develops a so-called bar at its mouth. The action and treatment of both these instances largely depends upon the fact that water flowing at a certain velocity produces considerable mechanical effect, so that in the condition described it is capable of abraded and holding in suspension solid matter in proportion to its velocity, and when fully charged its effective or abrading powers vanish, and any subsequent diminution in its velocity is attended by a corresponding deposition. The Mississippi is a river of this class, which has been deepened by the skill and energy of Mr. James Eads, whose advice was only recognised and carried into effect after a lengthened struggle, and the execution of which was attended by complete success. This river, highly charged with detritus, terminates in three mouths or passes, and the plan of operations consisted in selecting one pass, and constructing jetties on each bank, the entrance of the other passes being secured from scouring action by sills across their beds. By this means, the outflow in the one pass was confined within narrower limits, a higher velocity resulted, and the deepening of the channel took place. The jetties were so arranged as to determine the course and action of the river current at an angle with the littoral currents, the effect of which was to largely reduce the bar, and cause the detritus to be deposited to leeward instead of forming a fresh bar further out. On the correct determination of the external or counteracting forces depends almost entirely the success of such a scheme. The means adopted to carry out the work were specially suited to the circumstances and locality of the undertaking. No stone was handy, but in the neighbourhood of the pass there were large fields of rushes, which were plaited into wooden frames, so as to form mattresses, and these were subsequently floated out and sunk in position in a sufficient number of layers to attain the required height. After a lapse of time they became silted up, and formed a very cheap and effective form of jetty. The result accomplished by these jetties may be described as follows:—A channel was scoured throughout their length into deep water of 31 feet in depth, where before there existed in places only 10 feet of water, and a removal of 7,607,151 cube yards of material was effected. When we look at the enormous tract of country—24 times the size of England—which depends on the Mississippi as the natural outlet for its trade, we shall be able to form some idea of the magnitude and importance of the result obtained. Among other striking instances of the improvement of rivers by artificial means may be mentioned the mouth of the Danube by Sir Charles Hartley. An entirely novel theory in this direction is that advanced by Mr. Knapp, of New York, which is now being carried into effect for the removal of the bar at Sandy Hook. On the supposition that the bar is caused from the neutralisation of the river current by the wave action in the open sea, and the consequent deposit of the detritus held in suspension, he suggests the destruction of the wave force by building an artificial bar to a convenient height for the passage of vessels. The detritus, he argues, will thus be borne forward past the bar, and carried away by the littoral currents. Without the data to criticise in detail the theory advanced, it is probable there will be a tendency for the bar to re-form outside the false bar, in addition to which a construction of this class in deep water, and in an exposed situation, must necessarily be attended with serious difficulty and expense. The interesting phenomena offered by the river Mersey cannot now be discussed, but this

river may be considered to come under the second class of bar formation referred to.

Building Intelligence.

BODMIN.—Important additions are about to be made to the Cornwall pauper lunatic-asylum at Bodmin, which will supply additional accommodation for 170 patients. The main building will be two stories in height, and will exceed 250ft. in length. It will be planned with 10ft. wide corridors extending the length, opening on the ground-floor into day-rooms, and above into dormitories. At one end will be an epileptic ward, with attendants' rooms in close proximity. In the central portions spurs will be thrown out for both bathing-rooms, lavatories, and closets. All the drains will be extra-mural and ventilated. Detached for the most part from the new block, but connected with it and the main asylum by corridors, will be a dining-hall seated for 140 patients, with kitchen and offices in the rear, and in front of this detached building will be apartments for the assistant medical officers. The building will be erected and faced with a free-stone quarried on the estate, and now being raised by the patients. The plans, which have been approved by the commissioners in Lunacy and the Home Secretary, have been prepared by Mr. Norman and Messrs. Hine and Odgers, of Plymouth, as joint architects.

CHRIST COLLEGE, BRECON.—Some considerable additions to the school buildings have been lately completed from the designs of Mr. J. Bacon Fowler, architect, of Brecon. They are so arranged as to form, with the old school buildings and the fine thirteenth-century chapel of the college, three sides of a quadrangle. On the ground-floor are a range of class-rooms with a long corridor giving access to the chapel, lavatories, &c. Above are the large schoolroom, 75ft. by 25; science class-rooms, and studies. The walling and dressed work are in the local old red sandstone, and the style a simple Early English, intended to harmonise with the old work in the chapel and old monastic buildings. Forest of Dean stone has been sparingly used in mullions where necessary. The contractor was Mr. Wm. Bowers, of Hereford.

GLAMORGAN.—St. David's Church, Ystrad Rhondda, Glamorganshire, has lately been opened for service. It has been built at the sole expense of Mr. Crawshay Bailey, a large owner of property in the neighbourhood, at a cost, including approaches, levelling, and boundary-walls, of about £6,000. Seats are provided for about 560 persons. The church consists of nave with south aisle of equal span, chancel, vestry, organ-chamber, N.W. tower with small spire. The cost of the building itself has been about £1,500. The materials are the local Pennant stone walling, with Bath-stone dressings and green Whiteland slates. The work has been carried out by Mr. C. Shepherd, of Cardiff, from designs by Mr. J. Bacon Fowler, architect, of Brecon.

LEATHERSELLERS' HALL.—This Hall in St. Helen's-place, Bishopsgate-street, which has lately been rebuilt, has been fitted up from the designs of Messrs. A. T. Arrowsmith and Co., of 80, New Bond-street, London, who have completed the following works:—In the livery hall, 72ft. by 37ft. with a large bay window, an elaborate carved oak dado, 10ft. high, has been introduced, with parquet panels; pilasters with ornamental caps, festoons of fruit and flowers, and other decorative features. This fine hall, which is 35ft. high, has a plaster ceiling and cornice to an Elizabethan design, and this style has been adhered to throughout. A massive oak screen across one end of the hall, embodying the details of the dado, forms a prominent feature in this room. The reception room, 34ft. by 27ft., has a handsome oak carved and panelled dado, 1ft. 6in. high, with a bold chimney-piece and overmantel to correspond, and a solid parquet floor of the pattern laid by the same firm in the green drawing-room, Windsor Castle. The tiled hearth, sides, and back in this room and the hall have been specially designed, and the company's crest introduced with very good effect. The dog-grates have also been specially designed. The ceiling and cornice are in plaster, and harmonise well

with the other details of the room. The entrance-hall, 58ft. by 12ft., has an oak carved and panelled dado, with chimney-piece in the same character. The floor is paved with encaustic tiles, and the ceiling and cornice are finished in plaster. The above works have been carried out under the superintendence of the company's architect, Mr. G. H. Wilson, of 2, East India-avenue, E.C.

MEASHAM.—A Roman Catholic church has been opened at Measham, in Derbyshire. The chapel is built of red pressed brick, with stone dressings. The nave is also to be used as a school. The altar and reredos are of Caen stone, and stand some distance in front of the rear wall of the chancel, so as to allow a passage between them. The work has been executed by Messrs. W. Beckworth and Sons, of Whitwick, and carried out under the superintendence and from the design of Mr. C. G. Wray, F.R.I.B.A., architect.

ROUSDON.—The mansion, lodges, farm-buildings, church, and school, which have for many years past been in course of erection for Sir Henry Peck at Rousdon, near Seaton, on the eastern coast of Devon, have just been completed. The group was illustrated in the *Building News* for June 26, 1874, and the schools in the issue for May 12, 1876. The church is in the Decorated style, and consists of nave, short transepts, and chancel. The mansion is Late Tudor in style. From the chief entrance the centre hall opens on the left into the great hall, which has an open-timbered roof and ceiling, panelled walls, and parquet floor—all of oak; the windows, six in number, have been filled with stained glass representing historical scenes connected with Devon, and have been executed by Messrs. Lavers, Barrand, and Westlake, of London. To the right of the ante-hall is the morning-room, where the fittings, including parquet floor and mantelpiece, are of oak and walnut. At the rear of the hall is a quadrangle, of which it forms one side, the south wall being faced by the drawing-rooms and dining-hall; the east by the library, Sir Henry Peck's private rooms, and an invalid's suite of rooms; and the fourth side by the domestic offices, a projecting wing being thrown out for the kitchen, housekeeper's room, still-room, &c. In the basement under the great hall is a bowling alley, and under the south frontage a well-appointed dairy, besides various cellars. The principal bedrooms are placed on the first floor, and, like the lower rooms, have carved oak or teak fittings; the corridors have oak panelled walls and ceilings, and the floors are composed of mosaic work. On the attic floor are more bedrooms, and in the west wing is a large museum. To the west, and separated from the main building by a paved yard, is another huge block, including stables, workshop, offices, lofts, and stores. The original architects were Messrs. Ernest George and Vaughan, of London, but on the death of the latter the firm became George and Peto. From the first, Mr. George Moass, of Exeter, has been the builder. In the erection of the mansion, Mr. Moass has been joined by Mr. Redway, of Exmouth. Of the carved work, some has been executed by Mr. Harry Hems, of Exeter, and the rest by the firm of Smith, of London. Mr. W. Prosser has acted as clerk of the works.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—The first ordinary meeting of the session was held at the Association Rooms, Queen's College, on Tuesday, the 6th inst., under the presidency of Mr. H. H. McConnell, Chairman of the Association. Reports from the class secretaries and the librarian were read by the hon. secretary, who also presented a report on the visits which took place during the past session. After the business, the Chairman delivered an address, which was of a very interesting character, and at the close of which a hearty vote of thanks was accorded to Mr. McConnell. On Saturday last, the 17th inst., a visit was made to the new public buildings at Aston, which are now almost completed. The party included Messrs. T. F. Proud, E. Wood, W. H. Kendrick, J. P. Osborne, J. Ellis, F. G. Hughes (hon. secretary), &c.; also Mr. John Rodd's, who is a member of the local board. Mr. Wm. Henman, the architect of the building, conducted the party.

"To a practical man with a taste for mechanics, and the bump of construction fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is, in concise information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Troughtonians*. Price Two-pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent Garden, W.C.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.

All letters should be addressed to the EDITOR, 31, FAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in series advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold); for France or Belgium, £1 6s. 6d. (or 33f. 30c.); to India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL., Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—C. G.—L. T. S.—J. B. and Co.—G. T. D.—H. H.—H. B.—E. P.—R. D.—M. D. Hy. Co.—W. B.—J. M.—J. W. and son.—R. R. G.—R. I. B. A.—B. of S.

A READER. (Yes, but not separately to the extent it is here.)—D. CURRY. (We think to you should be strictly in outline only, but other competitors will doubtless read the conditions as you seem inclined to, and it is quite probable, judging from recent instances, that the arbitrators, even if professional men, will not trouble themselves to see that the uniformity which alone ensures fair competition has been observed.)—B. D. (Batten's Sewer Ventilator is as simply as any; see advertisement on p. xiii., last week.)

"BUILDING NEWS" DESIGNING CLUB.

VIGNETTE. (It was impossible to notice every design owing to the large number sent. Your plan has the following defects: Larder faces entrance, hips to roof too steep. The details of staircase are not good.)—N. (Your entrance is wasteful, and the stairs ill lighted.)

Correspondence.

FULHAM INFIRMARY COMPETITION.

To the Editor of the *Building News*.

SIR,—In your notice of the designs submitted in competition for the above infirmary, the following paragraph occurs:—

"It is alleged that one of the conditions has not been strictly complied with by a certain fortunate competitor, and there seems to be a just ground of complaint, urged by some, that a few of the best plans have been overlooked, while others, which have been tinted in direct violation of the instructions, have been favourably viewed by the board."

As there are only two premiums, the second of which has been awarded to us, and as, in a subsequent paragraph, you describe our drawings as "a neatly-prepared set of plans, coloured," it seems impossible that by "a certain fortunate competitor" can be meant anyone but ourselves.

We shall therefore be obliged if you will allow us, in justice to ourselves, to state that our drawings are in no sense of the word coloured. They are finished in black and white throughout, and are, we think, and as Mr. Curry ex-

pressly stated in his report, in strict accordance with the instructions issued to competitors.—We are, &c.,

KEITH D. YOUNG,
HENRY HALL.

17, Southampton-street, Bloomsbury, W.C.
December 19.

SIR,—You were good enough in your last week's review of the competition plans for this Institution to say, that those signed "Desideratum" were well considered, but that you "objected to the position of the day-rooms which are placed between each pair of pavilions and are entered separately from the corridor, also the medical superintendent's house at the back of the administrative block."

Will you allow us to say, that we think you have overlooked the fact that, instead of the medical superintendent's house being placed at the back of the administrative block, we consider that side the front? We have studied, carefully, "aspect" in the arrangement of our plans, and have looked upon the south as the front, and not the back, of the institution. We have placed the doctor's house in the centre of this front, in the middle of its own grounds, and sufficiently far from the south boundary to leave a spacious garden round three sides of it. The patients' day-rooms are placed, as you say, between each pair of pavilions, entered, not directly from the corridors, but through lobbies, and we claim for this position the best that can be had. Like the wards, these rooms face the south and overlook and communicate with the large airing-grounds between the pavilions. They are sufficiently far from the wards to afford a complete change to the patients, and being placed on the same side of the main corridor as the wards themselves, the "clumsy" arrangement alluded to in a contemporary of last week of "driving the main passage of the interior between the wards and these rooms," as is done in the plans selected, as well as in nearly all the other plans exhibited, would be thus avoided.

We cannot but think the majority of the competitors have thought too much of the Margrave-road, and have, in consequence, sacrificed the comfort and convenience of the officers and patients to the idea of presenting an imposing front to that road.

In arranging our designs, we looked upon this institution as separate and distinct from the workhouse proper, as though it were 20 miles away; and we believe it is a rule with the Local Government Board, in all cases where practicable, to entirely separate the two establishments; and that it was the intention of the Guardians to do so in this case, is borne out by the instructions which they issued for the guidance of competing architects, which provide for a separate management and distinct staff. We, therefore, have provided but one entrance, though which everything for this institution, and every person having business with it, must pass; in the selected designs, however, the main entrance through the adjoining workhouse is intended to be used for all administrative purposes, while the entrance next the Margrave-road would be used for all other purposes; an arrangement, we venture to think, that will cause a divided management between the medical superintendent of the infirmary and the master of the workhouse.

We have also placed all our buildings well within the boundary lines of the site, and have allowed a distance of 70ft. between the pavilions; but in the chosen plans, the main wards are shown to extend to the south boundary line next the workhouse premises, and the patients using the balconies at the ends of the wards would be able to shake hands with the paupers in the workhouse airing-grounds. The distances between the pavilions are only 48ft., and at the narrowest end, between the water-closets and bathroom turrets, only 26ft. The open spaces around the main wards are further curtailed in these plans by the laundry buildings, which are placed on the ground in the centre of the south front, where they would discharge steam and stench around the wards, and probably into them through the windows.

It seemed to us far better to place the laundries at the top of the north end of the administrative buildings, where any nuisance arising from laundry operations would pass away far above the wards; and this arrangement has the additional advantage of being more economical, as well as avoiding the crowding of buildings on the site around the wards. It appears to us also

objectionable to place the deadhouse in front of the wards, as is done in the selected plans; and we cannot but think that it would have been better to have arranged the 10th and Lock wards in a manner to have precluded them from commanding a view of the main wards of the infirmary. The larder, too, the only one for the establishment, and which has to serve as larder, pantry, and dairy, and measures only 17ft. by 14ft. 6in., is placed at the south-west angle of the administrative block, where neither meat nor milk could be kept wholesome for three hours on a hot summer's day; neither does it seem to us right or convenient to place the larder on one side of the administrative block and the officers' messroom on the other, with no means of communication between them except by passing through the kitchen or scullery and crossing two corridors, and both so far away from the matron's and assistant-matron's apartments, as to preclude them from exercising the supervision and control pertaining to their offices.

All these points were carefully considered by us, and possibly by others (we had only time to examine the designs placed first and second); and if the referee had had fewer plans to examine and report upon, we are persuaded his award would have been very different from what it is.—We are, &c.,

WATKINS AND SCORER,
Architects, Lincoln, Authors of the design
signed "Desideratum."

Dec. 20.

SIR,—As one of the competitors for the proposed infirmary, allow me to take exception to a few points in your leading article of last week, and to express some opinion on the competition and the designs sent in. The writer of the article rightly says of the drawings, "many of which are hung so high as to make examination difficult or quite impossible." This was especially to be noted as to the ground-plans, half of which were in this position—viz., those under the mottoes M.D., Plan, The House of the Sick and Poor, Apropos, Economy, Sanitas, Beacon, Sic Omnes, Albion, Fit, L'Esperance, Home of Plenty, and Kirby Pedon. The ground-plan being the most important drawing of each design, and in the above mentioned cases it being impossible to see the relation of the several rooms to each other, &c., criticism becomes impossible, and I felt constrained to leave the exhibition, owning that it was an impossibility to form any correct judgment on the designs, owing to the hanging. The critic of the *Builder* owns the same, and does not attempt to compare between the several designs, giving reasons for his inability to do so, and expressing an opinion only on a few of the designs in proper view; the design "M.D." even is left out for this reason.

As to the design "Experience" in circle, it is not noticed that the ward bath-rooms and w.c.'s open into the balconies only, so that patients must go out into the cold air to make use of them, even in winter time, the balconies being without glazing, as they should be. These balconies would not be cheerful, since they are to overlook the workhouse grounds, while they add to the expense. In my opinion, the receiving-rooms are badly placed, being separated from the administrative block; the ward store-rooms and lift accommodation are insufficient. The flues from stoves in the wards are shown to cut obliquely through the floors, this being very expensive in construction, especially in fireproof work, whilst being weak. The accommodation in the male and female wards being equal, is against the conditions, and extension is provided for one sex only. The question of cost will, however, be the most important objection to this design; in the opinion of many it being impossible to carry it out as it should be, within the 10 per cent. prescribed by the conditions.

I believe if all the designs were estimated for, there would not be a difference of more than £10,000 between the cheapest and the most expensive sent in; yet, according to the estimates of the authors, there would be a difference of over £46,000. I estimated my design at a rate of at least 50 per cent. above that of "Experience" in circle, and many of the competitors at 40 per cent., including the authors of "Simplicity"; they should all be estimated at about the same rate. This question of estimated cost still remains the most important for the Royal Institute of British Architects to decide on concerning competitions.

Your critic makes a great mistake as to the design marked "Simplicity," when he says it is "shown by a neatly-prepared set of plans coloured"; there is no colour whatever on the drawings, and no objection could be taken to them, unless it may be the slight etching. The worst fault I find with this design is that whenever the extension-blocks would be built, the infection-wards would be done away with, and have to be rebuilt elsewhere.

"M.D." must be chiefly objected to on the score of too low an estimate, the plan I was unable to criticise; I also object to a letter by the authors in the *West London Observer*, endeavouring to prove that the design could be carried out for their estimate, and saying that the expense of parochial buildings is bringing a "scandal on the profession." These gentlemen should be careful they do not. I believe their design to be one of the most expensive. The design marked "Plan" has coloured drawings. The elevations of the design "Quod Petis hic est," should be objected to as against the spirit, if not the letter of the conditions, on account of the elaborate etching, imaginary shadows, curtains in windows, and such-like trickery. "Hôtel Dieu" has a long front building as administrative, blocking out for half of one side of corridor the light and air. "Experience" in oblong, coloured, is considered by many as one of the worst plans sent in, the blocks being so crowded together that light and air insufficiently surround the wards. Several designs are lumped together at the end of the article, as not meeting so fully the requirements as the designs previously mentioned. This is unfair to two or more of these, which, in the opinion of many well qualified to judge, would be far before some of those previously mentioned. It would appear that in this competition, as in others, designs badly hung or represented plainly and fairly are, therefore, bad in themselves.—I am, &c.,

HUGH M'LACHLAN.

45, Fenchurch-street, London, Dec. 21.

THE INSTITUTE v. THE PROVINCES.

SIR,—In some communications to the *Building News* on topics which I know to be of great interest to the profession, I have tried to lay down some definite propositions for discussion—viz., that the R.I.B.A. is not at present constituted on the best lines to consolidate the profession, acquire a legal status for architects, and put an end to unqualified persons assuming the title of architects, &c. In arguing these points I have ventured, as a vast number of provincial architects take the liberty to do, to question the policy of the uniform high rate of subscription and other details of the constitution and "reconstitution."

Mr. William Woodward retorts in a letter last week in which I find no argument, nor any proposition other than this—viz., that I am a "querulously expository" person, a "vague and unpractical" person, a "scarcely accurate" person, a "sneering" person, and an "unwise" person.

It is a matter of as little moment to the profession that Mr. William Woodward should thus have arrived at the personal opinion that an obscure person like myself is a fool (which it amounts to), as would be my still more definite personal opinion formed about Mr. William Woodward if I intruded it. This is argument after the fashion of old women.

Of one thing those who share the happy satisfaction as to the perfection of the "reconstructed" constitution with Mr. Woodward may be assured: that no amount of lofty and dignified "setting down" of querulous and irreverent persons, without condescending to reasons and arguments, will put down a widespread feeling of dissatisfaction that exists among a very large body of architects outside the Institute; and, as we are aware from the unheeded remonstrances offered, within the Institute also.

The lamented loss, since the above was first written, of a practical and vigorous president who at least recognised that provincial architects did not join the Institute as was desirable, will not, I venture to hope, be an end to the encouragement given to ventilate and discuss this question. I and others, I am sure, are prepared to be quite as definite and practical about details as anyone could desire when we find the fellow-architects associated in opinion with Mr. William Woodward willing to withdraw their heads from "the condition of comparative security"

afforded by hiding them in the sand, and condescending to join issue on general principles.—I am, &c.,

THOMAS DREW, R.H.A.

SIR,—I have read the correspondence on this subject with great interest; but throughout it seems to have been implied that the by-laws of the Institute are, like the laws of the Medes and Persians, unalterable. This of course, however is not the case, and if the provincial Fellows should consider certain specific reforms or amendments necessary, they could have a special meeting summoned for their full consideration. If the proposals were reasonable and likely to tend to the general well-being of the profession, they would, I believe, be supported by a great number of the Metropolitan Fellows, including our able President himself.

I hold myself that, at present, the membership of the R.I.B.A. is of very considerable advantage to a provincial architect—and feel sure that it would be for the great benefit of the profession at large, if every competent and respectable architect became a member. At the same time there is no doubt that the relations of the Institute with the profession in the provinces might be much improved, and I feel sure a way can and will be found to secure this end. For this reason I the more regret that Mr. Drew and some more of our friends in Ireland should have seceded when they did. If they had remained, their influence would have been of great value now that the question they had at heart having been specially referred to in their addresses by both Mr. Whichcord and Mr. Street) seems more ripe for consideration than it was a few years since.

In many ways the reorganisation carried out a few years since seems to have been very beneficial to the Institute, and I hardly think that the annual subscription should vary simply in respect of locality.

I should be very glad to see the working details of the thorough and valuable scheme suggested by Mr. Drew. In the mean time, however, it might be well to concentrate attention upon some more tangible and moderate alteration in the by-laws, and I would throw out the following as suggestions for consideration, believing that, although only comparatively slight alterations are indicated, they would, nevertheless, go a great way towards meeting the most weighty objections which have been urged against the present system.

I would, without going into minor details, propose therefore:—

Firstly.—That any provincial architectural society may submit its rules and by-laws to the R. I. B. A., and if these are approved by the council, such society shall, with any other further conditions which may be necessary, be formally acknowledged by, or affiliated to, the Institute.

Secondly.—That any architect being a subscribing member of a provincial society, so affiliated, shall upon his election to the membership of the Institute, pay the following reduced annual subscriptions, *viz*:—Fellows £2 2s., Associates 21 ls.—I am, &c.,

A PROVINCIAL MEMBER.

December 11th.

BUILDING-STONES OF SCOTLAND.

SIR,—With your kind permission, I would take the liberty of saying a word in Mr. Gowan's favor, in reply to letter of Mr. Trickitt of the 2nd inst., and also to give you people in London a hint as to the stone you should choose: I speak from experience and without interest in any stone for his not noticing Corsehill Stone among the many building stones of Scotland, and that is, that Corsehill stone is not sufficiently known and valued by you to be classified amongst those generally spoken of by Mr. Gowan.

Corsehill stone was only found when the Selkirk Junction Railway was made some ten years ago, and has only been used as a public quarry since then eight years. True, there was a small local quarry a short distance off, and very likely that Mr. P. had not been the agent for Corsehill stone, he might never have noticed it either. From reports I have heard, I believe a considerable quantity of Corsehill stone may have been used in London, but as this is only have been in use some four or five years, which is far from sufficient time to test a good stone, as I found when in London lately and noting how

the Corsehill stone was standing the "test of time," I did not find the result as good as I could have desired, I will name two places, with your permission, the Hand in Hand Assurance Office, New Bridge-street, and the small columns in front of the Law Courts.

In the analysis published (without signature), Corsehill stone contains too much carbonate of magnesia, being 1.23. The analysis of Pleau stone given by Mr. Trickitt at same time, will be a much better weather stone, containing only decimal 52 of magnesia. Spinkwell, Cliffwood, and Robin Hood stones in Yorkshire, contain only decimal 5 of magnesia, and those are as near weather proof as possible. The excellent red stone from Newbiggin, which Mr. Street preferred for restoring the Fraternity at Carlisle Cathedral last year contains decimal 9 of carbonate of magnesia, while a sample of old red stone (supposed to be from Newbiggin), sent from Carlisle Cathedral for an analysis by Mr. Creed, Clerk of Works under Mr. Street, contained decimal 7. The less magnesia contained in this class of stone the better weather stone you will find it.—I am, &c.,

GEO. SOMERVILLE,

Carlisle, December 14th.

CLERKS OF WORKS.

SIR,—I am somewhat taken to task in the last number of the *Building News* by "One C. W. more" for having linked builders' foremen and clerks of works together, as being by occupation and association in want of a society to enable them mutually and conjointly to gain a more liberal and extended knowledge of their duties. I think, however, if he gives the subject more consideration, he will admit that, although temporary employment may sometimes be gained by "ratepayers' representatives," yet in nine cases out of ten clerks of works are chosen on their merits. Indeed, the intelligent carrying out of an architect's design in the spirit of its author is so essential a matter that the greatest discrimination is necessarily given in the selection of a person fully capable of exercising efficient supervision; at least this is so when the architect himself has the selection, and in the interest of competent clerks of works, this is luckily the rule, and the "ratepayers' selection" the exception. It is by reason of the responsibility that attaches to employment of this kind, and the valuable assistance which architects unable to be often at their buildings may gain by efficient representatives, that I am induced to think an association of the description advocated should receive a large share of moral support from the profession. I trust ere long to find some sign of this in the columns of the *Building News*.

That clerks of works and builders' foremen must not be classed together, I submit, savours rather of affectation; the very ancient title of clerk of works has to do duty now for all kinds of offices—the inspector of some village drainage works, or the jobbing carpenter of a petty landed estate, both claim that distinction, or have it thrust upon them, while their occupations would be declined by the builders' foreman of the most modest aspirations. There being no royal road to a knowledge of the duties required by a competent clerk of works, and those duties being of a nature requiring long practice and careful observation, builders' foremen, selected by the builder himself from the more competent men in his employ, are, naturally enough, the source from which clerks of works are recruited, and no better school could be devised; but although a thorough practical knowledge of one building trade at least, and a fair acquaintance with the remainder have thus been gained, there are still other qualifications necessary to enable them to become architects' representatives, and to obtain and make use of these qualifications is the principal object an association of this kind should aim at. The positions of a clerk of works and of builder's foreman on any building need not be inimical—in fact the good feeling and earnest desire to help each other, which should and does exist where both are disposed to do their duty by their employers and their employers' client, would be vastly enhanced by the knowledge that they individually belonged to an association for mutual help.

No class of men are so isolated in their occupation, as far as their knowledge of each other extends, as clerks of works; no means exist of

obtaining employment by those seeking it, but by personal application on the chance of a vacancy, or by advertising their wants, and no source is available for architects requiring the services of a competent man, except by inquiries from fellow practitioners or the advertising columns of the trade journals.

A society of the kind sketched would be able to remedy these difficulties to some extent.—I am, &c.,

ANOTHER CLERK OF WORKS.

SIR,—Your correspondent, Mr. Shore, wants to see clerks of works, builders' foremen, and others in the trade in friction with each other. Now, I maintain that the clerk of works is not in the trade, but of the profession. No doubt friction with the trade might brighten him up a bit, especially when, from unforeseen circumstances, he and the trade may have to change places; but the simile of friction is hardly technically grammatical. Friction against is the way I or a mechanic would express such a rubbing.

For a full-fledged clerk of works, too, it is rather late in the day, and it would be decidedly *infra dig.* for him to enter the lists with builders' foremen and others in competitive examinations upon building construction. I think his position ought to qualify him to preside as the teacher or judge, before even the builder on the one hand, or the architect on the other. A clerk of works ought to force himself to the front by his works and deeds upon tangible structures growing under his hand, and not upon sheets of paper. Neither will such papers serve him in the least when he has finished a job and is ready for another.

If he happens to be brother's sister's husband, or the forty-second cousin of a member of a committee, or if he knows a little of the ropes of some political caucus or club, he will find that his best credential. Doubtless he will sometimes have to deal with a proprietor who is spending his own money, but such a proprietor will generally leave the appointment, as he should do, to his architect, or else he will employ a *quasi* clerk of works direct, and expect him to act as a second architect, either with or without the approval or the plans of the gentleman who will hereafter have to play the second fiddle.

But, supposing the architect has the making of the appointment, if the job is near home and there is a good understanding between him and the contractor, he will push one of his elder pupils into the berth; and I do not blame him either, provided the said pupil has a reasonable aptitude for practical workmanship rather than for fine art.

But, supposing the job is fifty miles away, and the chances are that the builder will cut up a scamp, then will the architect look out for an experienced and trustworthy clerk of works. He will look for a man who can go upon the scaffolds and teach a young bricklayer, who is willing to learn, how to lay bricks, and who knows how to make it hot for an old one who isn't willing. The architect may be proud of his pupil's prowess in the competitive examinations; but in his clerk of works he will want a man who can make workable details in pencil to a big scale on the cheapest of cartridge, and which, when they have served their purpose, may be taken to wrap parcels in.

If the clerk of works can write a readable monthly report, which the architect may furnish up and transmit to his clients, then the C. W. will find himself rapidly rising in his employer's confidence, and, when the building is completed, if he has been reasonably cute and discrete in measuring up the extras, the architect will give him another job if he has it in his power to; but, if he be not a Street or a Scott, the chances are he will not have it, and so, he will give him a testimonial. If he is a gentleman he will commence it with "My Dear Sir," and a shake of the hand, and a friendly figurative kick, and he may go and get another job as best he may.

Now the Society that will avail for a clerk of works must have for its fundamental basis—first, a registration of all such as can produce, say, three such testimonials from F.'s or A.R.I.B.A.'s. That would place it, to begin with, under the wholesome patronage of the profession, and the less the builders have to do with that society the better for the morals of the nation.

The superstructure must be a sort of Freemasonry, without the secrecy, which shall serve

a brother ship as well at home as at a hundred miles away.—I am, &c.,

ONE C. W. MORE.

INSTITUTION OF CIVIL ENGINEERS.

SIR,—The advantage or disadvantage to non-Metropolitan practitioners of belonging to the Royal Institute of British Architects being now under discussion, it may not be out of place to make the same inquiry relative to the somewhat similar "Institution of Civil Engineers."

I have been a member for a good many years, but have found little or no benefit from it beyond having a copy of the *Proceedings* every quarter (not always very interesting to the bulk of the subscribers), paying three guineas subscription, attending perhaps one or two meetings in the session when within reach of London, and having the doubtful privilege of being entitled to write "M. Inst." after one's name in addition to the "C. E." that most draughtsmen and clerks of works can assume.

Practically the whole affair is in the hands of a few London engineers. Those in the provinces, in the colonies, and in India have not the slightest voice in anything, and they represent the bulk of the members. The "Balloting List" for the president, vice-president, and council for 1882 has just been circulated; but as, by the by-laws, it must be "presented personally," the election is entirely in the hands of some 200 or 250 members and associated members, to the total exclusion of the remainder of the 2,692 "corporate members" (as per last list issued) who by reason of not living near London are unable to attend. The names, moreover, are "nominated" by the outgoing council as "suitable," and do not include a single candidate intimately connected with the Colonies, India, or the Continent, by residence in those parts.

As a proof of the local interest that actuates our council, many of us will bring to mind the storm of virtuous indignation with which they met the insinuation of the Indian Government, through its Secretary, General Strachey, R.E., in 1869, that commission was taken by engineers from both employers and contractors. Their protest elicited a qualified withdrawal of the insinuation; but General Strachey was not far off the mark in making it, as there is not the slightest doubt that such a practice, although of course not "recognised" by any one, was often carried on. In my younger days, when pupil to a well-known member in excellent practice in Westminster, it was a regular thing for me or one of my fellow-pupils to be the bearer of letters to contractors asking for the commission due, and it was so far openly done that the notes were sent into the office to be addressed, &c.

Later on, in 1864, I was assistant to a large metropolitan contractor, who was believed by his own staff to have fed the engineer, but in articles of worth, not in cash. So much for the home clique.

As a proof of the lack of interest in non-local matters by the council, the profession generally will remember that, some time in 1879, the Indian Government decided upon enforcing a wholesale exodus of civil engineers for no earthly fault of their own, but because the finances were out joint. If I am rightly informed, a full representation of the facts was made to the council by some of the Engineers and a most reasonable request made that they, as representing the profession, would address the Government on the subject (no officers in the service being permitted to combine in an address on their own behalf), but not the slightest notice was taken on behalf of more than 300 men liable to fall under the sweeping resolution, the majority of whom were, I believe, members or associates of the Institution. In this instance the only one of any position who moved a finger in favour of the Civil Engineers was that straightforward and worthy officer, Colonel Sir Andrew Clarke, R.E. So much for any good derived by non-resident members.

The "extra commission" insinuation touched the dignity of the council and elicited a furious rejoinder—the contemplated dismissal of 300 engineers did not affect the council except perhaps to overstock the English market, and so enable assistants to be obtained at a cheaper rate. Hence things were let slide.

In my opinion such anomalies should cease, and were the council representative more of the

civil engineers of the world, and less of those of the metropolis, it would be a step in the right direction. I would propose that—

(a) The balloting list should contain the names of all those "eligible," leaving the members to decide who are the "suitable" ones, not the out-going council.

(b) It should be forwarded as a stamped proxy paper to everyone of the 2,700 corporate members in time for its receipt by return mail from the antipodes before election day, and so not be left entirely in the hands of some 8 or 9 per cent. of those entitled to vote, and who alone can be present to do so.

(c) It should contain the names of any eligible (and willing) members well known in, but who have retired from, the various colonial and Indian services, who are now resident in this country, and who by their varied experience and intimate knowledge of men and work in those localities, would form an invaluable addition to the council and tend to keep up friendly feelings with those abroad. Those eligible would all be men of more or less leisure time. One might be returned as the member for the Cape, another the member for India, a third the member for Australia, &c., and each by corresponding with some of his old friendly constituents might insure a continuous supply of papers and memoranda concerning work carried on in those places which would be infinitely more interesting to the general practitioner than the interminable scientific and often very abstruse quotations from Continental papers with which the *Proceedings* are now filled up.

It may be said that the constitution of this Institution does not admit of such a plan being carried out. If so, and if the Institution is never to be of more use to the profession generally than it is at present—a reading-room and library for Great George-street engineers, and entirely managed by a party of those gentlemen nominated by themselves—the sooner the constitution is altered the better.—I am, &c.,
December 14. P. PLAYFAIR.

PUBLIC SAFETY IN CASE OF FIRE.

SIR,—Invariably, on recurrence of a calamity such as that of the "holocaust" at Vienna, we hear from all sides of the defective arrangements of public buildings, and the old fallacy is raised of the narrowness of the approaches, stairs, &c. It cannot be too often insisted on that this is all beyond the mark.

I think it may be demonstrated that in the case of actual panic, the wider the passages the greater is the crowd, and the greater the danger. The worst crush I ever experienced was in a 50ft. road, with a panic crowd of not more than 2,000 persons. It is a mere truism to say that, under ordinary circumstances, a crowd moves quicker through a wider avenue than a comparatively narrow one; but, on the actual occurrence of a panic, we do find that the width of the passage does intensify the "momentum" of the rush. Granted, it is possible to increase the width of the approaches to such an extent as to insure absolute safety; it is equally true that the limits of practical convenience would be reached long before the limits of even comparative safety could be approached.

By this time, I think, most people must be convinced that the evil can only be avoided by subjecting all "assemblages" to practical and systematic discipline, such as soldiers have to experience, and such also as the "assemblage" itself submits to when actually landed and housed inside the auditorium.

There can be but one system of absolute safety—viz., by keeping in Indian or single file, and, as in our day at any rate, this cannot be enforced on a crowd by inducement, instinct, or habit, it should be attained by artificial means.

In brief, I would insist upon the division of every passage, entry, or staircase, into parallel gangways by permanent and substantial longitudinal barriers, allowing but one person to traverse; take, say, 2ft. as a unit (possibly in some cases less may suffice), every 4ft. passage would have two lines, 6ft. three lines, 10ft. five lines, and so on. Carry this down the stairs to the entrances, and get over at once all notions of appearances and the like.

It will be objected that no concourse will submit to be drafted off or arranged in this way. Will they not? and why not? Do not assemblages submit to, and even court all kinds of

inconvenience, discomfort, and danger in getting into a concert-room or theatre, and renew the same in getting out? and when once inside a building are they not practically in the position I would assign them in entry or egress—viz., filed off and arranged artificially in single files? "aligned," as military men say. Why should one object to walk in a confined restrained row, and yet not object to sit or stand in a similar position? Is there anything more objectionable in being placed in marching order than in rank side by side?

It is worse than useless to cavil about the defective arrangements of a building (often bad enough, Heaven knows) when the remedy is so clearly in the hands of the public itself.

Our modern system of collecting a mass of people, of locating them, and dispersing them, as clearly invites disasters as ever did the unskilful dispositions of a rash or incompetent officer precipitate defeat.

The two cases are parallel; you could not get a body of troops into military formation and dismiss them like schoolboys, each man for himself, without the certainty of the corps dissolving into a struggling mob. Similarly at a theatre, what is a panic or alarm of fire but a sudden "word of command" to disperse? And if the assemblage is without discipline, and incapable of acting in obedience to systematic direction, there is but one alternative—viz., move or guide the mass artificially in a definite direction, like rail or tramcars on a fixed track. The late Mons. Jullien used to urge that a theatrical panic might be prevented by playing the people out with an appropriate march tune. I do not know if the experiment was ever tried, but there is something in it, and, anyway, it points to the application of a system such as I have herein suggested, which may possibly not be either novel or untried, but is not the less deserving of earnest practical consideration.—I am, &c.,
D. BRADY, F.R.I.B.A.

December 19.

FIRES AT THEATRES.

SIR,—In thinking over the late lamentable fire at Vienna Theatre, an idea has occurred to me which, I think, would be a means of saving both life and property when these unfortunate catastrophes take place.

I would propose that ordinary iron gas-tubing of a suitable size be fixed on the stage side of proscenium, up the angles of walls, around proscenium, and all other places where they could be most conveniently and effectively fixed; also a large rose in centre, with holes drilled in this, and pipes to discharge the water at all angles, and that these should be supplied direct from the principal main water-pipe in the street, and that the stop-tap from same should be fixed at a convenient place near the outer door, next street, so that in case of fire the water could immediately be turned on, and would then fly in all directions, and be self-acting, at the same time would not interfere with any hose being applied by firemen.

The same means could be applied to the auditorium from another stop-tap fixed near the one for stage, with proper indicator for each. The pipes for this side could be fixed to form a member of the cornice at ceiling and other convenient places, where they would be most useful.

It appears from published accounts of Vienna Theatre, that all appliances of modern invention were provided to prevent spread of fire, but in the excitement, the whole of these were of no avail; and, at the same time, the great rush of people on an alarm of fire, that naturally takes place, interferes with the duties of officials, and prevents many of these appliances being used as intended. But the arrangement of pipes, as suggested, with taps fixed, where no rush could take place, and near an exit, where fire would not interfere with the working of them for some time, it would be in every way self-acting, and, with many holes in the pipes, at least 3-16 or a 1/4 of an inch diameter, would discharge considerably more water than many fire-engines, and, with the holes drilled at various angles to cover all parts, must, I think, be most effective, and would be at work instantaneously on the water being turned on; and, should the iron curtain be let down, would not interfere with the audience, and *vice versa*, should the fire be on the auditorium side.

Of course, these pipes need not be turned on only in case of other means failing.—I am, &c.,
G. N.

A. A. LECTURES.

SIR,—There seems to prevail amongst the members of the Elementary Class of Design, a healthy uncertainty as to the kind of "basilica" that they are to submit at the next meeting.

In the lecture on Roman Architecture a *Hall of Justice* was naturally alluded to, and the Basilica of Maxentius pointed out as a type of the vaulted construction that distinguishes Roman from Greek work. The wooden-roofed and colonnaded form adapted and adopted by the Christians is, of course, equally eligible, so long as no Christian distinguishing features be introduced into the students' designs. The general subject for the class, "A Temple or Church," must in this case be construed as a "Temple of Justice."

As there is no opportunity of making this explanation at an ordinary meeting, in time for the next class, your kind publication of it will be of service to the students.—I am, &c.,
Dec. 22, 1881. E. J. TALVER.

THE LATE MR. GEO. CHILDS.

SIR,—I did not know Mr. Childs, but I was born and bred in Islington—remember Old-road being built—and, indeed, lived in it in after years, I believe, in the very house (No. 21). So, being an Islington man—although I don't seem to belong to the class of men you appeal to—there can be no possible reason why you shouldn't accept my guinea to go towards helping the widow and the orphans. Here it is enclosed, and with much personal satisfaction I send it.—I am, &c.

LARRY HEMS.

[We have also received a sovereign from "H. A. C." for the same purpose; we should be glad to add any further subscriptions to the above and to remit them as early as possible to Mr. Childs' widow.—Ed. B. N.]

THE LATE MAJOR MANT.

SIR,—I trust you will give me space to say a few words in justice to myself, as Major Mant's principal assistant for the last seven years, with reference to your report of Mr. Spiers' communication at the meeting of the R.I.B.A. on the 5th inst.

Mr. Spiers says that Major Mant trained Indian talent, and employed native draughtsmen to work out his designs, especially ornamental detail.

As a fact, Major Mant did train two men, natives of the Carpenter caste, who were excellent draughtsmen in capable of doing original work. These men, who were brothers, were employed by him up to the middle of 1875, the time I joined him in Calcutta—not 1876 as stated by Mr. Spiers.

I, indeed, took their place in his office as one of them fell ill, and returned with his brother to Bombay, where he died soon afterwards.

I managed Major Mant's office from 1875 to the time of his death; I had the assistance of the surviving brother on the Baroda and Kolhapur Palaces after we returned to Bombay in 1878; but, other than this, I had no assistance for original work from any native draughtsman.

I may also mention I have been instructed by the Kolhapur and Baroda States to complete the working drawings of these palaces.—I am, &c.,
JOHN FOTHERINGHAM.

13, Springfield-road, N.W., Dec. 21st.

TESTING TRAPS.

SIR,—Referring to the discussion on various forms of traps that has for some time past been going on in your journal, may I express a hope that the prominence which has therein been given to various forms of cast lead-traps will not eventually lead to their general use in the place of those made by hand, i.e., "bossed" out of ordinary drawn lead-pipe? I have found in practice that the cast traps are not to be relied on for perfect soundness. I have found small holes or perforations in them, resulting I should say either from the use of inferior metal or a defect in the process of manufacture. I find also they will stand little or no "bossing" without cracking, and as very few are ever fixed without requiring some alteration or a change of form, &c., to adapt them to the required position, I consider this a serious drawback. I have, therefore, quite given up the use of the larger sizes (1 in. &c.) for closets, &c., preferring to have my own

"bossed" from pipe, which any men find no difficulty in doing readily to almost any shape.

The small "O" traps (cast) 2 in. and 1½ in. I still use for lavatory basin-wastes, as they have little else to do than keep back draught, the ends of the waste-pipes being always open.

I cannot, of course, make a "O"-trap as described, but as I myself consider this form full of defects, I shall never willingly use another, and I believe a few years hence it will be a "thing of the past."—I am, &c.,
CHAS. H. RAINGER, Mem. San. Inst.
Cheltenham.

CHIPS.

Mr. Beesley, C.E., of Westminster, reported to the Redditch local board, on Monday week, that the sewerage contract had just been thoroughly completed from his plans by Mr. George Law, in less time than was specified, and at a total cost to the town of £8,545.

The Hull corporation opened in committee, on the 15th inst., tenders for the erection of a pumping-station for the west district. Twenty tenders were received, and in consequence of the large difference between the highest and lowest—upwards of £9,000—they were referred to the borough engineer and a sub-committee, to examine and report upon.

The work at the new Eddystone Lighthouse was brought to a close on Saturday week, when the large staff of workmen who had been engaged there all the summer, under the personal direction of Mr. Edmond Douglas, was brought ashore for the winter.

A new stone pulpit was last week placed in St. Mary's Church, Cambridge. It was supplied by Messrs. Cox and Sons.

A new hall for public meetings was opened at Balham last week. Mr. Kerr was the builder.

With reference to the danger of fire in theatres, the Metropolitan Board of Works received, on Friday, a report from Mr. Geo. Vulliamy, their superintending architect, recommending that the act-drop curtain of every theatre in the metropolis should be lined with very fine felt, soaked in some chemical solution, such as tungstate of soda, that it might resist the action of fire for a few minutes. The subject was referred to the chief officer of the fire-brigade, and to the consulting chemist, for consideration and report.

In response to the appeal for £10,000 to complete the restoration of the west front of Lichfield Cathedral, the Dean and Chapter have received, up to the present time £7,000, including £1,000 offered last week by one individual. The work will therefore proceed. The north transept doorway to the cathedral has just been restored, under the superintendence of Mr. J. Oldrid Scott, as a memorial to Mrs. Bickersteth. The lower portions have been cleared of earth, and the cement repairs of the last century have been replaced by sound stonework. A communion table, in Roman cement, of 17th-century date, has been removed from the tympanum and the vesica recess has been filled by a figure of Our Lord in glory, and the original small censuring angels on either side happily survive the efforts of both destroyers and restorers. Between the double doors was a second female figure in Roman cement; this has been replaced by a statuette of St. Anne, in which the features and figure of Mrs. Bickersteth are represented to future generations. The work has been executed by Mr. Bridgeman, except the figure last mentioned, which was carved by Mr. Ingram.

A handsome lych-gate has just been erected at the entrance to the graveyard of the new Episcopal church of St. Andrew's, Fort-William. Lych-gates are picturesque features rarely met with in Scotland, although by no means novel in some parts of England, especially in Kent. Throughout the country only two exist, this one at Fort-William making the third. It has been designed by Mr. Alexander Ross, of Inverness, and is of a massive character. It is made entirely of English oak, grown in Devonshire, and has been carried out by Mr. Harry Hems, of Exeter. The lych-gate has been put *in situ* by Mr. George Harrison, one of Mr. Hems' staff, and with the exception of a few tiles, is now complete. The clerk of works, who has superintended the erection, is Mr. Alexander Fridge. The work is the gift of Mr. G. B. Davy, of Spean-lodge, Kingussie, who has commissioned Mr. Hems to carve sculptured doors for the western entrance of St. Andrew's church. These doors, designed by Mr. A. Ross, are of the same class as Ghiberti's celebrated gates at Florence, and in a series of panels will illustrate our Lord as the Door and the Good Shepherd.

Mr. Edward Phillips, managing director of the Crown Porcelain Company, Derby, died on the 15th inst., at the age of 65.

Intercommunication.

QUESTIONS.

[6830].—**Book on Asylums.**—What is the best book published on lunatic asylum planning, and the price? Also, could any of your readers kindly tell me of a book giving outline drawings of the figures of Apostles, Saints, &c., with their emblems, suitable (or reference by an architect).—F. M.

[6831].—**Damp Wall.**—I have a long red-brick wall with S.W. aspect, and which catches the full force of all the wind and rain from that quarter. Is there any mixture other than paint which will render it impervious and not unsightly? Information would be gratefully acknowledged by—J. D.

[6832].—**Soil-Pipe.**—Is an external iron soil-pipe the better or worse for being galvanized? Would the sewer-gas and the soil and urine have any detrimental effect on the spelter coating of the interior of the pipe, or would they set up any galvanic action to the destruction of both metals if they penetrated any small pin-holes which might be left in the galvanizing process?—R.

[6833].—**Cleaning Old Engravings.**—Will any reader kindly inform me of the best method of cleaning old engravings, or refer me to a number in which such a receipt may have been published?—C. E. C.

[6834].—**Civil Service.**—Will any subscriber kindly answer the following queries? Is it desirable for an architect's assistant to compete for an assistant to surveyor's post in the office of H.M. works? What is about the number of vacancies and competitors per annum? Can I obtain copies of past examination papers, and where? What books are the best to study to insure a pass? Any information respecting above will greatly oblige—ALPHA.

[6835].—**Ventilation.**—I have several very large rooms to erect for public use, wherein will be many people assembled and much gas burned. I object to the system of admitting cold air into a room full of vitiated air, as it chills the same, and, falling to the level of the ionates, it is inhaled and poisons the lungs, especially when the rooms are reopened in the morning, after the air has had sufficient time to thoroughly cool. I also object to all self-acting extracting ventilators, as they are entirely dependent on the wind passing across the outlet, therefore, when most needed, fail. Should I be successful in adopting the following method—viz., small openings at upper part and lower part of walls, to be carried by shafts to sides of ash-hole under the furnace bars of the boiler, which is to be used for supplying hot water for warming purposes, and during the hot weather hot water to pipes shot off, and small fire kept up in furnace, expense of coal being very small in the neighbourhood.—A. V.

[6836].—**Damp Walls.**—I have just finished a dwelling house, the outside of which is plastered with Portland cement 2 in. thick. At times the rain beats hard against one wall, and I find the plaster on interior is quite damp and discoloured, although the wall is 20 in. thick. I thought first the rain might have made its way in through window-frames, so I had these tightly caulked, but without any good effect. The ceiling beneath where roof meets chimney is also damp, and rats must be getting in there, although there are step flashings and top flashings of 6 lb. lead. The party who had contract of roofing says the rain must be getting in through brick joints of chimney, but these are well pointed with fine mortar, and I think the damp must be getting in through some bad workmanship in slating. I would be thankful for some information as to means of remedying these defects, especially the damp walls.—NOVICE.

[6837].—**Floors.**—What weight per superficial foot is allowed in calculating strength of floor to be used for dancing? 8 lb. per superficial foot is weight of a crowd of men closely packed. Will this be sufficient? Is the weight of floor itself considered in calculating bearing power? What is the usual weight of a floor executed on the "single" or "naked" principle, not framed?—SODA PLOOMS.

REPLIES.

[6760].—**Sp. G. and Crushing Weight of Stones.**—Mr. Hugh McLachlan falls into a curious error in supposing that two of his own native Scotch stones, known technically in the market respectively as "Corsehill" and "Dumfries," are one and the same material. There is no more likeness between the two than exists between Ancaster and Ketton, Boxground and Corsham, or Aubigny and Caen. Corsehill is a fine-textured material, not at all unlike, but much harder worked than, Mansfield. Dumfries, on the other hand, is coarse grained. Upon Corsehill the shrapnel arms may be easily obtained; but delicate moulds or carvings are not pleasantly worked in Dumfries stone. Mr. McLachlan, after referring to the crushing weight of Portland as 14, and that of Corsehill as 531, says, "the expense of working stones, I believe, generally increases with the strength and hardness of stones." By this theory Corsehill would involve more than three times the labour that Portland does, yet every practical reader knows, as a matter of fact, that the labour in Portland and Corsehill is about the same.—HARRY HEMS.

[6761].—**Chimney.**—"B. S." though giving much useful information, and having a practical knowledge on what he writes, omits to answer the question put by "A. Young Builder," who asks whether a chimney 10 yards high with an inner casing will not give a better draught than one without? In my opinion it would, for the following reason, that the inner casing would prevent the air and smoke inside the flue being so quickly cooled as would be the case without it, and the warmer the air inside, the greater is its velocity and therefore the better the draught. Further, the air inside the chimney with the inner casing would be lighter than inside the other without. "B. S." fairly questions whether "lining" is not a better term than "inner casing." In my opinion both are incorrect, and I do not know of a suitable term. "B. S." questions whether the "inner casing" is to be recommended unless there is a large space between it and

the wall, because it would get filled with soot and dust; the reason appears insufficient; first, would it matter were it so filled? I think not; second, would it be filled? If properly built it should not, as soot and dust could not make their way through the brickwork. Also, the furnace should be smoke consuming, therefore no soot should find its way into the cavity over the top of the lining, neither should it succeed better when a shaft is over 8 ft. high. There is much to be said both for and against iron casings, but the best argument would be found in one of ultimate cost. In other particulars I agree with "B. S."—HUGH MACLACHLAN.

[6765].—**Glazed Earthenware Flue Lining.**—"Smoke" by his question brought out useful information, from which I believe much may be learnt. "Satisfied" says that in his experience of glazed drain pipes no fall of soot occurs, whilst "B." says the objection holds good with unglazed pipes. I would have thought that the unglazed would have been better, but this experience says quite opposite. Possibly the reason is to be found in that the glazed retains no soot, letting any little which does not escape fall at once, whilst the unglazed retains it until it can hold it no longer or a storm loosens it, when all comes down together. It is the same with brickwork, only that the pores being larger, so much soot adheres that it is generally swept away before it falls. If glazed pipes are used, they should be most carefully jointed, that the joint's retain as little soot as possible; as to the question of "C. F. M.," I do not think so, it might occur if the pipes were too tightly built in. If the flue retained hardly any soot it could not catch fire and for general use the pipes would expand as the heat increased.—HUGH MACLACHLAN.

[6770].—**California and Colorado.**—California is as well settled, and the competition among workers as great, as Eastern States. Consequently that State does not offer the best inducements to emigrants. A gentleman who, like the querist, has had architectural training, and is well up in construction, &c., would do better in one of the middle States. Colorado, being overrun with silver seekers rather than by men engaged in the less risky work of farming, does not offer the chances that are offered by Missouri, Kansas, Minnesota. Let not the querist expect to make a fortune quickly. Professional men are very abundant, but there is always room at the top. But whatever is done, let my friend avoid Texas and emigration sharpers. If he is active, energetic, and willing to do whatever comes to hand, he cannot fail.—R. M. TUTTLE, Providence, R. I., U.S.A.

[6771].—**Deadening Sound.**—Sound will even penetrate 14 in. walls of brickwork, and if house-builders considered it a *sine qua non* that all party walls should be sound-proof, as they undoubtedly should, they would build all party walls of at least 15 in. brickwork or of hollow walling. "Mancuman" may try either of two plans, both of which I believe are effectual, or nearly so; the first is, cover each side of the brickwork with felt, batten over this, and then lath-and-plaster; the second supposes the wall plastering and papering untouched, it is simply to hang that side of each room next the party wall with batten or some heavy woollen material from ceiling to floor; the worst of woollen curtains is, they harbour dust.—HUGH MACLACHLAN.

[6772].—**Timbers in King Post Roof.**—In the case given, 4 in. The scantlings given are correct, but all the timbers are often made of the same width to have an even appearance on face, or, in other words, to be flush at the joints, hence the struts and sometimes the king post are made stronger than is constructionally necessary, thus in the case given the struts would often be made 4 in. by 2 in. or even 4 in. by 3 in., instead of 3 in. by 2 in., for appearance sake; this is what is meant by the note.—HUGH MACLACHLAN.

[6776].—**Moss on Wall.**—See my answer to No. 6345 in BUILDING NEWS, May 20 last. Several years ago a correspondent recommended a weak solution of sulphate of copper, also known as bluestone.—HUGH MACLACHLAN.

[6777].—**Measuring Chimney Breasts and Stacks.**—In London these are measured solid, the fireplace openings alone being deducted. In Manchester also solid, the fireplace openings and flues being deducted, extra lineal allowance being made for labour in the latter case. I find the following answer in the BUILDING NEWS, October 5, 1877:—"There are different methods of measuring chimney breasts in Yorkshire—1st, by the lineal yard, each toe measured. 2nd, by taking the girth of breasts—face and projections only—by the height up to roof, calling it all 9 in. work, if built 4 in. 3rd, width of breasts by height by projection, brought into cube yards, as high as roof, above roof girth round, and charge whatever thickness it is, 5 in. or 9 in. Take 5 in. mid-fathers to separate flues above roof, yards superficial. The latter I consider to be best. If the breast is in a 9 in. wall, the wall is measured behind the breast as 9 in."—HUGH MACLACHLAN.

[6778].—**Drain.**—The method proposed would probably effect only a partial relief, as the well would only tend to drain from all the surrounding area. Try method proposed by "Lewes" in answer to No. 6313 in your issue of the 16th inst.—HUGH MACLACHLAN.

[6779].—**Measuring and Charging.**—It is unnecessary to prepare a fresh bill of quantities. The best method is to prepare a separate bill of extras and credit for the "provisional items," setting one against the other, and allow extra or deduct as the case may be. Sometimes when the extras and deductions pretty well balance, a system of "give and take" is carried out; this, though simpler is not so business-like. If the total amount of variation is very small, no notice is generally taken of it.—HUGH MACLACHLAN.

[6780].—**Extras.**—If the contract required a "written order," I do not believe "Ignoramus" could claim under it, but I do not think it would prevent his claiming and successfully any orders given before witnesses, as outside the contract.—HUGH MACLACHLAN.

[6781].—**Lager Beer Breweries.**—As far as I know there are no books on these special breweries, though there are one or two works on breweries. Scamwell's "Breweries and Maltings," for instance. Perhaps it might pay "A Young Subscriber" to visit a few of the named breweries abroad.—HUGH MACLACHLAN.

[6782].—**Architects' Charges.**—Charge for time used in preparing drawings and tracings. "A. Benton" would, however, be ill-advised, were he to charge for the time occupied in preparing unsatisfactory plans. Work of the kind named is often done by pupils on their own account, it being simple in character: it is therefore better to make the charges light than heavy.—HUGH MACLACHLAN.

[6783].—**Builders' Estimates.**—It would be difficult for a builder to sustain a charge for estimating, especially when he has had work to carry out.—HUGH MACLACHLAN.

[6794].—**Problem.**—W. S. Daws was quite correct when he said all three answers were wrong; but that he himself gave the correct answer is another question. His sweeping assertion led me to examine the question more closely, and before seeing W. J. Christy's reply in issue of 16th, I came to the same conclusion as it contains, viz.: that £157 2s. 10d., my previous answer, was the proportionate price paid by A, at the first for the last three years, but, as the amount has been idle for 10 years, A is entitled to compound interest, which at 4 per cent. equals £75 9s. 2d., making the total sum to be paid by B, £232 12s. It stands to reason that B should pay less purchase money proportionately than A, as he has to pay an increased rent per annum "G. B. L.," "J. R. R.," and "G. B. Lincoln," ignore this, and their replies are, like my first, wrong.—W. U. O.

[6794].—**Problem.**—"Coker" has now 12 replies, all different. This is astonishing! My way of looking at the matter is very simple. A. paid £1,050 out of pocket, and was entitled to receive from B, 4-14ths of this, equal £300 plus compound interest for ten years at the standard rate of 5 per cent., which would bring it to £488 or thereby. The increase of rent to £300 after A. retired should not affect A., because he gets no benefit. The property, after 10 years' occupancy by A., will have increased £50 per annum in value, and I cannot see why he should pay to B. any part of this increase; if he did, B. would be sitting at the same rent as A. was, which would obviously be unfair. But assuming it to be the case that A. is agreeable to pay this proportion of the increased rent, then A. would deduct 10-14ths of £200; the increased rent equal £142 17s. 1d. from above, making net amount £346, or thereby.—EDMUND.

[6805].—**Bath.**—I recommend "Alba" to hack over present face of his swimming-bath and lay over and well trowel in a coat of Parian cement. I have little doubt but that this will be found effective.—OLD BUILDER.

[6805].—**Bath.**—I have found floating with good plaster of Paris very effectual in a similar case.—W. P. R.

[6813].—**Water.**—In a somewhat similar case, where the basement floors of a store were rendered useless by the surface-water soaking into and lying to a depth of 2 ft. on the pavement, I had a trench dug all round outside walls, to a depth of 2 ft. below floor-level. I then rendered the outside of the walls in half Portland cement, half sand, and laid 4 in. agricultural drain pipes, with a regular fall in the trench, which I continued to deep pit, which I had dug at a distance of 30 ft. from store, over the pipes I packed in rubble stone for a depth of about 2 ft., and then covered in the earth as before. This experiment was tried three years ago, and at a recent inspection, after three weeks' continuous rain, I found the place so dry that floor was stored there in sacks. I should have mentioned that the floors are of brick-on-edge in mortar, and that I also ventilated this by putting in air bricks close to ceiling, and by admitting fresh air. If "Urgent" will try the above, I am sure he will have no more trouble.—W. P. R.

[6813].—**Water.**—To "Urgent," I should reply that no plan such as he suggests for asphaltizing or cementing will permanently answer in keeping back the water. I have frequently experienced the difficulty he names. For the use of water from land springs there is no remedy but drainage—best with loose cobbles or an open stone drain on one or more sides of the buildings. But if the water is 12 in. above the cellar-floor level it may be necessary to raise the floor. This is evidently an instance of hurry and imperfect acquaintance with the ground. It seems very strange that the springs should not be discovered till now. I have often hailed the occurrence of water this way as a perfect "godsend," it being sometimes the only way of obtaining any water at all. Cellars should, in country places, be always made of good height, not less than 8 ft. 6 in. from floor to ceiling, to allow for drainage. You may often get a good cistern tank or well when there are land-springs. The occurrence of water this way frequently arises from cross cutting of some old land-drains, which should be noted during progress.—B.

[6816].—**Cracked Sewer Pipe.**—In a position where some 15 in. pip. s were laid 2 ft. below surface, heavy artillery waggons and guns had to cross almost daily, and the pipes were smashed. I had concrete laid down in bottom of trench 1 in. thick, and laid the pipes (at same level) thereon. I then had rubble walls 18 in. thick built and turned a 9 in. brick in cement arch over, so as to allow 6 in. between top of pipes and intrals of arch. This was a success. Concrete would have been used for walls and arch, but I could not give it time to set.—W. P. R.

[6821].—**Colour on Parchment.**—As the quality and grain of skins differ, so will be the result of your work, but having had a large experience in putting plans, &c., on deeds, I will endeavour to instruct "An Old Subscriber," at the same time advising him to procure some old piece of parchment and experiment on them first. Over the part to be worked upon rub a little test dry whiting, and with a soft cloth rub it all off again. This will take out the greasiness of the skin. I then generally draw my plan in pencil, and with a brush and clear water go over the parts to be coloured, blotting off carefully the surplus moisture; then proceed to colour as required, and when dry ink in, and with the majority of cases you will be successful. Another way is to cut out in tanning paper a pattern of each tint and stencil in; but this requires great practice to make the colour lie evenly. Let your skin dry gradually and naturally, never putting it by the fire, or it will wrinkle up. A little gall with the colour greatly assists the drying, and if there is a large surface to get over, mix up enough so that it may be

taken from the top; the heavy particles settle at the bottom, and your plan will not appear patchy.—LEWES.

[6821].—**Colour on Parchment.**—Allow me to give "An Old Subscriber" some information, arrived at after colouring several hundreds of skins. First line in and put all writing on with Lion ink, mixed thinly, but not brown; then clean the plan thoroughly and well rub French chalk into the skin, but not so thickly that it can be scraped off with a knife. Mix colours thinly, and allow the grosser part of the sediment to settle. Do not use earthy colours if possible, and never burnt sienna. Lay on the full strength at once. Tilt your drawing-board on an easy inclination, and work with a full camel hair brush, allowing the colour to flow over the surface, but not to stay for any length of time whilst colouring another part. I never use gall—it is too searching. I find the perspiration of the hand sometimes affects the skins. With every precaution some skins turn out speckled; the surface seems gone, and the skin absorbs the colour in places like a sponge. I think it is sometimes caused by a rough chalk the solicitors use when engraving the deed, but more generally by irremediable defects in the skin itself.—C. M.

[6821].—**Colour on Parchment.**—Edge the boundary with border pen, taking care that the colour does not go over the line, so as to have the effect of adding to the area concerned. For portions built upon score finely, say 30 to the inch on property concerned, and 20 to the inch on that outside and adjacent. Rubble water with writing pen and let the text of deed refer to portions "edged" one colour or another; thus ditto tints are un-called for. Roads, streets, or thoroughfares are best left untinted, as the printing on them explains their nature, independently of colour.—ASOTUR SUBSCRIBER.

[6821].—**Colour on Parchment.**—A bad skin will never take the colour evenly, however carefully laid on. The mark of the brush on a large surface may be caused by going over work partially dried, or by using too much gall in the colour. If "An Old Subscriber" will rub the skin gently with soft indiarubber on the parts to be coloured, I think he will find the colour lie evenly, if the skin be a good one. A little touch of gall will assist.—W. J.

[6821].—**Colour on Parchment.**—"Gall and other little things usual in general work" are quite unnecessary in colouring on parchment. Rub well all over with indiarubber before commencing work; a Wolf's paper-cleaner, large size, I find best, refreshed on a sheet of coarse sandpaper when it becomes glossy. Do not attempt to colour across ink lines, but up to them on each side. Keep the skin at a good inclination, say 30°, and work the colour downwards with rapid and short strokes of the brush from alternate ends of its lower edge, using plenty of colour. Surfaces on parchment will always have a patchy and uneven appearance if not properly coloured; but it is only a small percentage of skins which finish "speckled," and for this I know of no remedy. "An Old Subscriber" gives no idea of the actual dimensions of the surfaces the colouring of which gave him trouble; but it might be possible for him in future to suggest to solicitors that instead of the words "thereon coloured red" they might insert "thereon surrounded by a red line," thereby reducing the draughtsman's labour and adding to the neat appearance of their deed.—C. R.

[6822].—**Making New Pavements.**—The owner of house-property must conform to the by-laws of the district, and only a fair and reasonable charge can be made for the paving. I presume he would be only responsible for paving to length of his frontage, unless the house abuts on to two roads.—LEWES.

[6823].—**Width of Roads.**—The local road surveyor is right if the fence shades the road. See 5 and 6 W. L. 4th, cap. 50, section 74; and again sections 69 and 80, section 82, deals with the compensation. Country lanes are highways, and are, under this Act, streets, generally under local boards.—ROBERT PHILLIPS, Surveyor of Main Roads for Gloucestershire.

[6825].—**Surveyor's Licence.**—The law says, "If any person effects an appraisement which is liable to stamp duty, in consideration of any fee or reward, direct or indirect, without being duly licensed as an appraiser, he is liable to a penalty of £50." The licence is issued by the local Excise officer of the district, and costs £2 per annum. It is, therefore, always advisable for a surveyor to have a licence.—LEWES.

[6825].—**Surveyor's Licence.**—This question has been asked several times through your columns. "Every person who values or appraises any estate, real or personal, or property for, or in expectation of hire or reward, without being licensed, is liable to a penalty of £50, and he must set down in words or figures every valuation made by him on paper duly stamped, under a penalty of £50—i.e., if the valuation is to be binding between two parties with opposing interests. Persons calling themselves surveyors who act as valuers require a licence. It costs £2 a year, and is obtainable at the office of Inland Revenue. The licence expires 5th July after its issue.—J. SMITHCOCK, Hitchin.

[6826].—**Heating Apparatus.**—I have in several cases used "Grundy's" system with perfect success. The apparatus is the less costly, produces more heat, and consumes less fuel than any other plan, and there is no risk of fire, and easy to manage. The air is heated in an air-chamber, usually constructed in a vault under or near the church or under vestry floor, and passing through a flue comes in through an iron grating in the floor of the church. At the same time the apparatus draws out through another grating the cold air, and, heating and purifying it, sends it back again. By this simple plan the entire church is brought to an even temperature. Mr. Grundy's address is Tyldesley, near Manchester.—LEWES.

[6826].—**Heating Apparatus.**—Write W. Porritt, Dixon Green, Bolton, Lancashire. The apparatus is used for large as well as small churches, successfully. Chamber 11 ft. in length, including stove-hole, covered by grating 11 ft. by 2 ft. Flue must be carried up above highest ridge, say, in gable end-wall. In cases of very long dues a pilot stove is employed to create draught. The apparatus is on the warm-air principle, and the risk none. Costs from £7 10s. to £15, and fixing should not exceed £12 to £15 approximately.—W. U. O.

[6828].—Granite Pavements.—"Pegasus" wants a paving stone that has not "a tendency to wear smooth or become slippery." I have found the Irish and Scotch granites to keep their roughness, but they wear away very quickly under much traffic. The Portland stone is also a better wearing stone, so also is the Cleve Hill stone, than either the Irish or Scotch granites. The Portland stone retains its roughness better than the Cleve Hill. The hardest and most durable stone is the Welsh granite "Sydney," from the Great Mountains, and the grey variety of trap rock from Penn-y-nnar; but these, like all hard stones, have a tendency to become smooth, but for durability they are excellent, and none better. I therefore recommend "Pegasus" to try the Portland stone.—*Experienced.*

[6829].—Concrete Roof. "C" notices appears the only cause of your dampness. There will be no objection to your ceiling with lathed out, or painting the exterior surface. I doubt, however, if you will find any benefit therefrom.—*Lawyer.*

LEGAL INTELLIGENCE.

WEBBER V. THE LONDON, BRIGHTON, AND SOUTH COAST RAILWAY COMPANY.—(Supreme Court of Judicature: Court of Appeal.—Sittings at Westminster, before the Master of the Rolls and Lords Justices Brett and Cotton.)—This was an application on the part of the railway company for a stay of execution pending an appeal to the House of Lords. The plaintiff, an architect, alleged negligence on the part of the defendants six years before action, in consequence of which an accident occurred, the results of which to the plaintiff were at first not serious, but that afterwards locomotor ataxy supervened. The defendants denied the negligence, asserted the plaintiff was not suffering from locomotor ataxy at all, and declared that the injuries sustained by the plaintiff were of a trifling character. The jury found a verdict for the plaintiff for £500, being of opinion that, although there was a gap in the plaintiff's evidence which prevented him from proving that locomotor ataxy was occasioned by the accident, yet he was entitled to those damages on the ground that the injuries caused by the accident, though not locomotor ataxy at all, were still serious. A Divisional Court granted a new trial on the ground that the verdict was unsatisfactory as regarded the amount of damages. The plaintiff appealed in person to the Court of Appeal, urging that the damages were not excessive, and the Court came to the conclusion that the damages were not excessive irrespective of the locomotor ataxy. The plaintiff, therefore, succeeded in his appeal. Mr. Murphy, Q.C., on behalf of the defendants, now applied for a stay of execution pending an appeal by the railway company to the House of Lords. The Master of the Rolls refused the application. Lord Justice Brett was of the same opinion. Lord Justice Cotton concurred.

LIEKELLING A DISTRICT SURVEYOR.—(Before Mr. Justice Mathew and a Special Jury.—Knightley v. Lett).—This was an action for libel, in which the defendant pleaded justification and privilege. The plaintiff, Mr. Thomas Edward Knightley, is the district surveyor for Hammersmith, and has held that position for the last 19 years. Defendant, Mr. Edward Lett, is a retired solicitor and copyholder of certain property, including 25 cottages, known as Montpelier-row, Hammersmith. Some question had arisen as to the condition of the property, and the plaintiff held a survey, and directed that repairs should be executed upon three chimneys and an out-house. The defendant subsequently took proceedings against the lessee of the property, and subpoenaed the plaintiff to appear as a witness. The plaintiff did not attend the trial, and the defendant, after asking for and failing to obtain an explanation from the plaintiff, wrote to the Metropolitan Board of Works, complaining that the plaintiff had attempted to extort money from him by refusing to appear at his subpoena unless he was paid three guineas, and also stating that the plaintiff neglected his public duties by attending to his private business in Cannon-street, and only having a clerk to represent him at Hammersmith. In consequence of these communications the plaintiff was summoned before a committee of the Metropolitan Board of Works, but after an inquiry into the circumstances the case was dismissed. The plaintiff explained that he had not attended the trial owing to the advice of the defendant's solicitor that his evidence would rather injure than assist the defendant's case against the lessee, that the fee of three guineas had reference to an application by the defendant to survey the premises in a private capacity, which he was anxious to avoid, and that by the regulations of the Board of Works he was allowed to carry on his private business out of the district; but he was always in attendance at Hammersmith every Tuesday for ten hours, and every Friday for eleven hours, while his clerk was in attendance in the office during the whole week. The jury gave a verdict for the plaintiff, with £100 damages, and judgment was given accordingly. Mr. Justice Mathew, on an application by the defendant's counsel, and there was no ground whatever for a stay of execution. On Wednesday, however, a rule was granted for a new trial.

THE FALL OF HOUSES IN THE HAYMARKET.—*PERCIVAL V. HUGHES.*—(Queen's Bench Division. Sittings in Banc, before Mr. Justice Grove and Mr. Justice Bowen.)—The following considered judgment was delivered on Wednesday morning by Mr. Justice Bowen. The action was tried in December, 1880, before Mr. Justice Manisty, when a verdict was found for the plaintiff. A rule was subsequently obtained for a new trial, and was twice argued, the second time in June last, before the Lord Chief Justice, Mr. Justice Manisty, and Mr. Justice Bowen. The facts of the case will be found in the judgment, it being only necessary to add that the house in question was one of those that it will be remembered, fell in the Haymarket during last year. Mr. Justice Bowen: The question raised in this case is whether the defendant is liable to the plaintiff for damage done to the plaintiff's premises through negligence on the part of a contractor's man during the operation of rebuilding the defendant's house. It was admitted at the trial that the wall which divided the two houses was a party-wall, and that by the fall of the defendant's new house the party-wall was damaged, and injury caused thereby to the house of the plaintiff. It appeared that the defendant's new house was one story higher than the defendant's old house, and one story higher than the plaintiff's. The defendant employed competent architects and builders. In the course of the work the defendant's new house had to be carried down lower than the plaintiff's house, and the party-wall accordingly was under-pinned. A portion of the party-wall was taken down as far as the first floor. Upon the day of the accident the contractor's men were setting the steps of the staircase, and they, without authority, cut into the portion of the party wall that had not been removed. The architect, on discovering what was being done, and seeing the danger, ordered measures to be taken to prevent a settlement; but while these measures were being carried into effect a settlement took place in the plaintiff's house. In the evening the defendant's house collapsed and fell, doing the damage to the plaintiff's house which is complained of. Upon the above facts, Mr. Justice Manisty, before whom the case was tried, ruled that the plaintiff was entitled to the verdict. The question for this Court now is whether such ruling was correct. It appears to us that the learned Judge was right in his view of the law. The defendant had employed a contractor to perform work involving the disturbance of the plaintiff's party wall, and dangerous, therefore, to the support of the plaintiff's house. The defendant, in other words, being bound to do nothing to deprive the plaintiff's house of its support, had employed a contractor to execute works which might endanger it. The defendant could not relieve himself of the responsibility arising from such an operation simply by employing a competent contractor. It still remained the defendant's duty to see that effectual means were adopted to prevent any damage arising to the plaintiff's premises during the progress of a work which was likely to be injurious unless sufficient precautions were adopted, and for which he himself had given the order. It was urged upon us that the mischief was caused by a negligent act of commission on the part of the contractor's men, done without orders. But this distinction cannot avail the defendant in the present instance. If the only duty cast on the defendant had been the negative duty of abstaining from all acts which would damage the plaintiff's premises, it might with reason be argued that an act of commission done by workmen in violation of their instructions rendered neither the contractor, their immediate master, nor the defendant himself liable. But the duty of the defendant went further. It was to see that at all times, during a hazardous operation, set in motion by his orders, effectual support was given to his neighbour's house. This was a positive obligation, not a negative one. He was bound not merely not to sanction injury, but to prevent it. For wilful acts of mischief he might not indeed be responsible; but it was his duty to hinder negligence whether in the shape of acts of commission or omission. As the defendant has failed to fulfil this duty the plaintiff is entitled to succeed. The case appears to us to fall within the principle of "Bower and Peake" (1, "Q. B. Division," 7) which must now be taken to have superseded "Butter and Hunter," (7, "H. & N." 826), so far as the cases are in conflict. (See "Dalton v. Angus," 6, "Appeal Cases," 11, L. J. 89.) The rule must accordingly be discharged, with costs.

Extensive improvements are being made in the Baptist chapel at Maesummer, including alterations to seats, building of baptistry and new vestry. The contractors are Messrs. Yeo Brothers and Mr. Evan Davies.

The great demand for the Ligna Company's joinery goods, and the increased business with which they have been favoured, has necessitated the requirement of more extensive premises, at 31, Eagle Wharf-road, New North-road, London, N.

Our Office Table.

In the Elgin room at the British Museum there has just been set up for public inspection an interesting attempt at the restoration of the missing portions of the famous statue of Hermes, by Praxiteles, found at Olympia. The restoration is on a reduced scale, and is the work of Miss Halse, the daughter of a sculptor, and herself, as this work shows, giving high promise in the art. The action adopted for the right arm of Hermes, which is missing in the original, is that of holding aloft a bunch of grapes to attract the attention of the infant Bacchus, whom the god carries on his left arm—a motive which had already suggested itself to archaeologists, although not generally accepted by them.

An art treasures exhibition in the Town-hall, Ryde, was opened yesterday. The Queen has contributed to it many works of art from both Windsor Castle and Osborne. The Ex-Empress Eugénie has also sent for exhibition a collection of water-colour drawings, and some of her private jewels. Lord Tweedmouth, Sir Richard Wallace, Sir Henry Daly, Baron F. de Rothschild, and other well-known collectors are also contributors. Among other attractions are collections of Wedgwood, some china, bronzes, miniatures, and articles of *virtu*, and a gold vase which was purchased at the last Paris Exhibition for the sum of 150,000*fr.* The collection of oil-paintings by old and modern masters, several of which are sent from the South Kensington Museum, is large and valuable.

A TRIAL of a newly-designed machine for scattering sand or salt in the public streets, with a view to the prevention of people and horses slipping and falling in wet or frosty weather, was made on Saturday afternoon last, at Camden-town, at the request of the London Street Tramways Company. The machine is invented and manufactured by the firm of Ben. Reid and Co., of the Bon Accord Works, Aberdeen, and consists of a modification or adaptation of their broad-east artificial manure distributor, which was tried at the recent show of the Highland Society, at Stirling. The apparatus is composed of a hopper, that may be easily affixed to the end of any sort of cart, and into this the sand or salt is filled as required by the driver. The action of the machine is both continuous and automatic. The conditions under which it performed its work on Saturday were unfavourable, a drizzling rain falling all the time; yet the distributor did good service and earned the encomiums of its judges. As the result of this trial, the London Street Tramways Company have determined upon the adoption of Messrs. B. Reid's invention for use in the thoroughfares traversed by their cars. In addition to the more effectual work, it was stated that a saving of at least 25 per cent. may be secured by the use of the new machine, compared with the methods hitherto employed.

A LECTURE on Tuesday evening in connection with the Leeds Philosophical and Literary Society was delivered by Professor Colvin, M.A., on "Raphael and Rembrandt: a Comparison." The lecturer, in the course of his remarks, said that it was impossible to look at the pictures of these two masters without immediately recognising what had been the chief aim of each. The three great elements in art were lines, light and shade, and colour. Of these three elements, Raphael had chosen the first, and made it his chief aim to portray in his pictures the distinctions of lines. Rembrandt, the greatest of a number of Dutch painters who had made it their object to delineate the distinctions of light and shade, had succeeded in that object to a further extent than all his competers. For an illustration of the third element, we should have to go to Venice, to the school of Titian, &c. Raphael is the master in whom all the efforts of his predecessors culminate. Rembrandt, living in a totally different era, has no past to look back upon, but looks to the future in his representations of the ugly and uncouth figures in which the variety of light and shade is so definitely and skilfully shown. Limestick illustrations taken from some of Raphael's and Rembrandt's greatest works were shown.

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 30, 1881.

THE PAST YEAR.

THE year which is fast hastening to its close has not been remarkable for the initiation, commencement, or completion of any great architectural work—it has rather been one especially marked by the loss of some of the most eminent members of the profession. It is, unfortunately, no new experience for those who, like ourselves, have depended so long on the cordial help of the best in the ranks of those we represent, to miss year by year old friends and faces; but never before in our recollection have so many seemed to go from us as it were almost at once, as during the last twelve months. Their work, however, is yet with us, and those of us who value it rightly will best interpret its highest lessons by a renewed determination to work as some of those worked who have left us, and to leave behind in our turn, if not such mighty works as they wrought, something that may not altogether shame the art whose achievements are among the most lasting monuments of human endurance and energy.

Mr. Street's greatest work has been left unfinished. The progress that has been made during the past year at the Royal Courts of Justice has indeed been considerable, and it is satisfactory to know that the design has been so far completed in its main features as to make the task of Mr. Street's successor comparatively easy. The great central hall and its surrounding courts have been carried out in all their main details, the public entrance and octagonal staircases have been nearly finished, the roof of the great hall is on, and the central flèche has made considerable progress. The numerous and carefully-prepared working drawings Mr. Street has left, and which formed so marvellous a display of handiwork on the occasion of the last visit of the Conference to the new building, leave really little but scrupulous supervision and the exercise of a faithful interpretation necessary. As the vast edifice has advanced step by step, we have noticed its salient points, all tending to confirm our previously expressed opinion of the wealth of resource and detail lavished by its author on every member and ornament of this complex structure. No Gothic building certainly of our time has exhibited to so great a degree the individual impress of the artist on its minutest detail.

Another great building, the progress of which we have watched from time to time, has been completed—namely, the Natural History Museum at South Kensington, and its architect, Mr. Alfred Waterhouse, A.R.A., has disproved the popular idea that the leading members of the profession have shown themselves unequal to the requirements of the age and in the design of buildings depending on skilful planning. Mr. Waterhouse's design for the Central Institution of the City and Guilds of London Institute, a perspective of which we gave in our Christmas number, is another notable instance of the use of red brick and terra-cotta on a large scale, and as a building of Renaissance character, it will rank as one of the most successful of its author. The first stone was laid by the Prince of Wales in July last. We may here also casually allude to the completion of the quadrangle of the New Court Chambers, in Carey-street, by the same architect, in which we discern some skilful handling. The New Town-hall, Hove, near Brighton, is another

work approaching completion by Mr. Waterhouse, in which the Gothic style has been adhered to, a central tower forming the main feature, and the progress made with the new Church of the Oratory, South Kensington, from the designs of Mr. Gribble, is worthy of record as an example of the application of marble bonded with the brick-work, instead of being used for a veneer merely, as practised in Italy. A detail of one bay of nave we recently published, Sept. 30, 1881.

During the year we have illustrated two theatres from the designs of Mr. C. J. Phipps: one the new façade of the Princess's Theatre in Oxford-street, and the other the new theatre recently completed in Beaufort-buildings, Strand, the front of which faces the Embankment, and is executed in red brick and stone. Both are designed in a free sort of Italian style (see illustrations, p. 360, Vol. XL). The Alexandra Theatre, in the Haymarket, is another addition to the number of new theatres which have been erected, from the design of Mr. T. Verity, architect. We noticed it in a recent number, on account of the improved provision made for entrance and exit to the chief parts of the house. The calamitous and melancholy destruction of the Ring Theatre at Vienna, resulting in the burning and death of over 808 occupants, has already stirred the authorities in England and the Continent to do something to avert such terrible and wholesale sacrifices of human life. The theatres of Paris have already been the subject of inquiry by a commission. M. Andrieux, Préfet de Police, has reported upon the topic at length, and his observations are worth the notice of all architects. The fitting up of an iron curtain which shall fall automatically by combustible cords in case of fire, the use of separate meters for each of the three divisions of a theatre, and the use of some solution, as tungstate of soda, to render the drop-scene and drapery less inflammable are among the points considered. Confining our attention here to buildings in the metropolis, we remark the progress that has been made at the City of London Schools by Messrs. Davis and Emanuel, on the Embankment, and near it the erection of Sion College Library, by Mr. Blomfield, M.A., will, when carried out, fill up the valuable frontage towards the river. These buildings are typical of the styles which just now seem to be in most request for educational purposes. Mr. R. W. Edis, F.S.A., has lately been engaged also in this part in enlarging and remodelling the Inner Temple Library, in King's Bench Walk—a plan and illustration of which we have recently given with a notice of the new building, and we can say the work is a successful adaptation of Late Gothic.

In the City a few important works have been either completed or are in progress. We must mention the completion in part of the new Fruit and Vegetable Market, and the opening of the first section of new Leadenhall Market, both for the Corporation, from the designs of Mr. Horace Jones, the City architect. We have only lately noticed the architectural features of these large public undertakings, and so need not say more now. The Standard Insurance Office, in King William-street, by Messrs. Boulnois and Warner, a building we have also referred to, is one of the best recent examples of Classic design applied to business uses, though the shape of the land has rendered the treatment of the main façade at one angle extremely difficult. The Law Courts Chambers, by Mr. Wimble, ought not to be overlooked. The offices of the London and Lancashire Fire Assurance Co., Cornhill, by Mr. Chatfield Clark, just finished, is a pleasing instance of French Renaissance: the front is of stone, and freely relieved by deep bands with carved orna-

ments between the coupled orders of columns which break the façade. Though not strictly within the category of architectural buildings, we must not omit to mention the enlargement of the Fenchurch-street Station, as a work of some magnitude.

At the West End, also, structures with some pretensions to architectural merit have been completed. We may refer to the new premises for the Life Association of Scotland, in Pall Mall, by Mr. Alex. Peebles, in which a Classic façade of one order has been employed, with an entresol arrangement in the ground-story. Messrs. Howell and James's new façade in Regent-street is a clever adaptation of English Renaissance features to business premises, in which red brick and terra-cotta have been introduced. In Pall Mall we must record the progress of the picture galleries, by Mr. E. R. Robson. Several buildings have been erected for charitable and benevolent uses. Among these we must mention St. Peter's Hospital, Henrietta-street, from Mr. J. M. Brydon's design, in which red brick has been used, and the style adopted is 17th-century Classic freely handled; we have given an illustration of it (p. 740, Vol. XL). The new Hospital for Consumption in Fulham-road, opposite the old building, has been completed, and was the object of a visit during the Conference week. The design, in a free brick style, was prepared by the late T. H. Wyatt, and the works have been carried on under the supervision of Mr. Matthew Wyatt. Another hospital for Consumptive Patients has been in progress, and is advancing towards completion, at Vernon Hill, Hampstead, from the designs of Professor T. Roger Smith; and in the same class of erections we must include the recently-built Hospital for Sick Poor in Marylebone, from Mr. Saxon Snell's design, which we have already illustrated (Vol. XL., p. 309). The building was opened a few months ago, and its chief peculiarity is the adoption of double pavilions of wards. The Holloway College, now erecting at Mount Lee, Egham, for the higher education of women, is a work of individual munificence not to be overlooked, and we cannot speak of this building without referring to the other great edifice undertaken by Mr. T. Holloway, the Sanatorium for Mental Diseases in course of erection, both having been designed by Mr. W. H. Crossland, and intended by their benevolent founder to be presented to the nation.

Many large residential blocks have been erected in different parts of London; chief among these is the Albert Hall Mansions, South Kensington, by Mr. R. Norman Shaw, R.A., recently illustrated (Vol. XL., p. 526), remarkable for its vast size and height, and as being one of the first instances of the use of Queen Anne features for buildings of this class. In Victoria-street, Westminster, another instance may be noticed; but the most prominent architectural work which has been in progress here is the large Army Hotel, from Mr. Pilkington's design, a structure we thought worthy of a special notice when reviewing this thoroughfare. It is sufficient to say here that the architect has boldly introduced a style of trabeated Greek detail little practised in London.

Numerous buildings of a commercial class have been erected in various parts of London. We can only point to the warehouses in Great Eastern-street, Shoreditch, from the designs of Mr. Aston Webb, which we illustrated in Volume XL., p. 294. New Schools of Art have not been few; we can only name in passing the West London School of Art, by Mr. R. W. Edis; and the Chiswick School recently opened, from the design of Mr. Maurice B. Adams. Amongst buildings of a domestic character, the mansion in Park-lane for Mr. Leopold de Rothschild, by Mr.

W. R. Rogers, architect, is conspicuous. Architectural progress in the provinces has not been distinguished by any very great undertakings. The University Buildings, Edinburgh, from the designs of Mr. R. Anderson, have made progress during the year, and are a group we have illustrated. Mr. A. W. Blomfield, M.A., is engaged in erecting from his designs, Selwyn College, Cambridge, an edifice in a Late Gothic style, and the same gentleman has recently carried out a new Training College (St. Katherine's) at Tottenham, in the same spirit, both admirably fitted for their respective purposes. The Exeter Grammar School, by Mr. W. Butterfield, is another educational work of an excellent type, also Gothic in style.

Of the few municipal buildings erected, that at Hastings, from the design of Messrs. Ward and Andrews, in a Gothic style, must be noted; but the greatest work of the kind still in contemplation is the Glasgow municipal buildings, for which the second competition among architects was invited at the beginning of the present year, and will shortly be under consideration.

In the batch of new provincial buildings, the Liverpool School of Art and the Newbury Grammar School must be named; the former design, by Mr. F. Cook, architect, we gave on Feb. 4, 1881, a work conceived in a rigid Palladian style, and worthy of a high place. The second premiated design we have also illustrated (March 11, 1881). The Newbury Grammar School, the competition for which was decided at the beginning of the present year in favour of Messrs. Power and Hughes, is one of the few works to be recorded as strictly belonging to the year's progress. We have illustrated the design. A college at Ellesmere, by Messrs. Carpenter and Ingelow, must be cited also; and Mr. Stuart Colman's Trade Schools, Bristol, must rather be placed in the list of competitive designs of the period we are reviewing. Illustrations have already appeared in our pages of the Bolton Infirmary and the Chadwick Museum, both by Mr. R. K. Freeman, in the Gothic style; the former was opened recently. Messrs. Mawson, Bradford, have finished the University College Buildings, Nottingham, which were opened last June, and among other large educational structures must be mentioned the Handsworth Theological College from the designs of Messrs. Dall and Goddard.

One very good example of Late Gothic, applied to a post-office, has been furnished at Hereford, and another attempt to use the style for secular uses has been made at Sheffield in the new Corn Exchange, by Messrs. Hadfield and Son, in course of erection, where a large rectangular hall has been introduced. At Ipswich, the new Post-Office and the School of Art, both of which we have illustrated, have been opened, and the new Corn Exchange, also illustrated in our pages, is being roofed in. New offices have been erected in Glasgow, West George-street, by Mr. J. McLeod, architect, in an Italian style, showing a rather richer treatment of the style than is generally found in that city. We can only enumerate here the erection of the Hereford County College, an illustration of which has appeared in our pages; the Northern Assurance Office, Newcastle-upon-Tyne; the High School for Girls, Manchester, by Messrs. Mills and Murgatroyd; a School of Art in the same city; the Devonshire Hospital, Buxton, by Mr. R. Rippon Duke, lately opened—a building with a circular domical centre. Markets have been erected at Dublin by Messrs. Lockwood and Mawson; and at Chester by Mr. W. H. Lynn; and Messrs. Paul and Bonella are engaged in building a Convalescent Home at Southport, Gothic in style, with terraces largely introduced.

We must notice, among secular buildings of the year, the Preston Railway Hotel, by

Mr. T. Mitchell, Oldham; important additions to Arundel Castle, for the Duke of Norfolk; Derwent Hall, Derbyshire, for the Duke of Norfolk, by Messrs. J. A. Hansom and Son; and Barrow Court, Chester, by Mr. J. Douglas (illustrated), in Late Gothic, with brick Flemish features, are noticeable works of the year, among which must be placed the re-casting of Eaton Hall, Cheshire, by Mr. Waterhouse; a large R. C. College at Weybridge, by Messrs. Hansom and Son; and additions to the Lancaster Asylum (a memorial wing), by Messrs. Paley and Austin.

A few buildings have been erected, or are in progress, at Brighton. We may mention the Hospital for Sick Children, by Messrs. Lanson and Son, and some large corner premises between West-street and King's-road, in a Renaissance style, by the same architects; and the new Town Hall at Hove, by Mr. Waterhouse, nearly finished. A grand hotel is about to be built at Aldershot, near the South Camp, from designs by Mr. G. Edwards; at Rotherhithe, Messrs. Elkington and Sons have been engaged in new baths and washhouses; Messrs. Perkins and Bulmer are carrying out their plans for the Pontefract Town Hall; and at Birmingham the new premises of the Midland Institute and the Central Fire Brigade station have been carried out.

The number of churches and ecclesiastical buildings is too large to allow us to mention even the more important of them. We may just, however, refer to a few important edifices of this class. The restoration of Lichfield Cathedral west front, and of St. Giles Cathedral, Edinburgh, have advanced a stage. The new cathedral about to be erected at George Town, Demerara, from the designs of Mr. A. W. Blomfield, M.A., is a bold adaptation of Gothic or Romanesque features to the climate. Mr. Butterfield is the architect of a cathedral at Melbourne in progress, and Messrs. O'Neill and Byrne are the architects of a new cathedral at Drogheda; and the new Truro Cathedral, now building, from the designs of Mr. Pearson, R.A., must be again noticed. We have illustrated churches at Devonport, by Mr. J. P. St. Aubyn; St. Peter's Church, Plymouth, by Mr. G. H. Fellows Prynne; a church at Camden-town, by Messrs. Bodley and Garner. Mr. J. Oldrid Scott is the architect of Lahore Cathedral, previously described in our pages. Mr. E. Ingress Bell has in progress a Catholic church and schools at Bromley (illustrated), and Mr. J. P. Sedding has just finished in Late Gothic the unique building St. Mary's-at-the-Cross, Shoreditch, we have described. Mr. Street restored the body of St. Peter Mancroft, Norwich, and the completion of its tower is still in progress. At Ipswich St. Lawrence's Church steeple, a lofty structure, is being clothed in masonry and flintwork, to a rich Fifteenth-century scheme, by Messrs. Barnes and Gaye. Messrs. Pugin and Pugin are the architects of a church and convent at Dumfries we illustrate this week, and a large church at Bayswater by Mr. J. Johnson is being carried out.

In the list of competitions or works recently commenced, we must name the Glasgow Municipal Buildings already alluded to; the Selby schools; the Harrogate Conservative club, determined in favour of Mr. A. Hiseox; the Cardiff infirmary, just illustrated by us; an infirmary at West Bromwich; workhouse at Burton-on-Trent, the Suffolk and Gloucestershire Lunatic Asylums, by Messrs. Giles and Gough, who have also just won the Fulham infirmary competition; the Burton-on-Trent market-hall, Mr. Dixon, architect. Competitions for the Rowland Hill statue and the sculpture for Blackfriars-bridge have taken place this year, but the work is still in abeyance; while the award of Sir Frederick Leighton,

P.R.A., in the last case, has been only tardily adopted, and, as we hinted last week, the selection of designs has been again referred to the committee for further consideration. Professor Hayter Lewis has been appointed assessor for the competition designs for a proposed asylum at Exeter; and a competition for St. Paneras Workhouse has been instituted on a liberal scale of remuneration, the names of five architects having been selected for the contest. The Birkenhead town-hall competition is another instance where the recent regulation in respect of a preliminary sketch test has been resorted to. The Brighton clock-tower competition has been abandoned, and some others are undecided.

Our rapid and imperfect sketch of the year's work would not be complete without making a reference to a few events of general import. The year 1881 will be remembered for another conference, in which the questions of quantities and competitions were discussed with a result, in the last instance, of something being done to promote fairness in conducting public contests between rival competitors. The principles and rules there laid down, the adoption of preliminary sketches, the promotion of properly prepared instructions, and the guarantee that the designs shall be examined by qualified judges of merit, are steps in the right direction. The commencement of tests of professional competency by the Institute, marks an eventful period in the progress of architecture which may lead to a change in the personnel of the profession in course of time. In matters of style little change has taken place, the Queen Anne or 17th-century revivalists still hold a prominent position among the profession, and a purer phase of Classic design is likely to be inaugurated. Gothicism has lost its great master and champion in the death of Mr. Street, and it reflects credit to the honesty of his convictions that he never pandered to fitful changes of style, but persistently followed the Gothic of his choice. Mediaeval art has, however, many able exponents and disciples left among the profession, who will honourably carry on a revival which has made the nineteenth-century in England a conspicuous one in the art-history of other nations.

THE NEW ACT ON CONVEYANCING.

WITH the New Year there comes into operation a very important statute relating to the law of real property. In its full title it is described as "an Act for simplifying and improving the practice of conveyancing," and for various other purposes. But the words we have quoted give the key-note of the whole measure, and fairly describe its aim and object. That our law of real property, especially in its practical details, needs a great deal of simplifying, and will stand any amount of improvement, is a fact that admits of no question. In going through this lengthy statute of 73 sections, many of which are in themselves very long, we find much that can only be fully appreciated by the legal student and practitioner. But still it is possible to pick out a few of the important changes made in the law and practice of conveyancing, and to present them in such a form that they may prove generally interesting to men of business who are often obliged to deal with land and houses, and to come in contact with the mysteries of the law of real property.

It is a common truism to say that the transfer of a piece of land should be as short, as simple, and as cheap a process as is the transfer of a ship. Yet, while no one disputes the theory, those who understand the question will doubt the possibility of putting it in practice. If we could get every piece of land in the country registered somewhere

as belonging to somebody, then the difficulties of title would be at an end, and the problem would be solved. But that great "if" stands, and has now for many years stood, right across the path of progress. Before a title can be registered by an authorized officer, it must first be examined by those who are skilled in conveyancing. But at whose expense is this vast work to be undertaken? Efforts have been made by various statutes, the last being in 1875, to get parties to register their titles; but the end has always been found in failure. The mere registration of transfer is of little or no avail; registration of title being, indeed, the one thing wanted. While we are waiting for this wide measure of reform there are, however, many things that can be done meanwhile towards making our system of conveyancing at once simpler and sounder, and cheaper in its practical working.

The main points upon which this reform is possible may be shortly stated; and they have been borne well in mind by those who framed the new Act. The existing blots upon the present system of conveyancing are mostly to be found in its prolixity and complication, and consequent expense. Upon each sale or mortgage of land or houses, whether freehold or leasehold, it is necessary to provide for every possibility. Thus the documents used are extremely lengthy, and are full of old forms and endless repetitions. Yet, unless the proper covenants and provisions are always duly inserted, harm may be done, and loss result to the parties concerned, by the happening of some event for which the deed has not provided. The only way to get rid of these needless forms is to enact that they shall *ipso facto* apply to every sale or mortgage, and, be considered as included in every deed, although they are not set out therein. It is upon this principle that the Legislature has often proceeded in the many statutes that have been passed during the present reign to patch up the law of real property, and the same idea has been followed in the Act now under our notice. The Vendor and Purchaser Act of 1874 did a good deal in this direction by providing that certain conditions of sale should be always applicable, and by other similar clauses; and in the latest measure of reform this plan is carried out much further and more fully.

Passing over the definitions, every one of which in its every line bristles with points of law to be settled and construed at the expense of future suitors; we come to some important clauses upon contracts for sale. Builders and others who buy or sell land or houses, know well the importance of the contract; which, though it is only a preliminary, requires to be carefully drawn, to prevent, or rather to anticipate, every possible dispute. It is obvious that if it be enacted that all the common clauses shall apply, as of course, to every such contract, the document actually required will be greatly shortened. Speaking broadly, and without going into details of too technical a nature, this is what the new Act has done. Independent of statute, a purchaser of real property has a right to a good marketable title, and the vendor is bound, at his own expense, to make out such a title. In order to get over this difficulty, no wise vendor ever sells without having a written contract in which he stipulates as to the kind of title he shall be bound to furnish. By the operation of the new Act most of the common clauses now put in these contracts by way of precaution will become needless, being applied thereto by the statute. So with regard to what are known as "general words" in deeds and documents. It has hitherto been essential to set out every possible right or easement that might be on or over the land sold: and for this purpose a long rignarole of words has been employed for

generations; adding greatly to the length and complication of every deed of transfer. For the future, the conveyance of land will carry with it all that can be covered by, or included in, these general words that have hitherto been used, and thus the mere piling up of words will become unnecessary.

Passing on, we find clauses dealing with covenants for title, which again are of the utmost importance, and cannot fail of having a widespread effect in shortening and, so far, in cheapening the usual deeds and documents. Upon every sale the vendor now covenants that he has good right to convey, for the purchaser's quiet enjoyment, that the property is free from incumbrances, and that he will execute any further assurance that may be necessary. These covenants are all set out at full length in the same form of words that has been used for centuries, and it is clear that as they are invariably inserted they may just as well be implied. This is the view taken by the new statute, and so it provides that in a conveyance of sale these four covenants for title shall be understood and implied, in the same way as if they were set out in the deed itself. Where the property sold is a leasehold it will further be assumed that the vendor covenants that the lease he sells is valid and subsisting. Upon a mortgage of leaseholds by the beneficial owner, the usual covenants for title as to good right to convey, quiet enjoyment, freedom from incumbrance, and further assurance, will be implied, and so need not be stated in the conveyance. With regard to other forms of transfer, there are similar provisions, into the details of which we have now no space to enter, while there are further clauses as to the production and custody of title-deeds which are of great practical importance.

The large question of leases is dealt with in a separate part of the new Act, which provides that the rent and benefit of lessee's covenants shall run with the reversion, as also shall the obligation of the lessor's covenants; while it is enacted that all conditions may, upon severance, be apportioned; and there are other like provisions too technical to be here considered. But the most important branch of the subject is that dealing with forfeiture. Under the present law, if a lease be once legally forfeited, no Court, even in Equity, can afford any relief, except where the forfeiture has arisen for non-payment of rent, or by default in the insuring. If, therefore, any lessee breaks a covenant to repair, for instance, the lessor can, if he chooses, take advantage of this breach and forfeit the lease: nor will any relief be afforded, even though the repairs be done and all damages and expenses fully paid. For the future, this summary system, which, though theoretically very hard, is, it must be admitted, seldom put in force practically, will be much modified. No forfeiture is to be enforced unless and until the lessor serves notice of the breach upon the lessee requiring compensation, and the lessee fails within a reasonable time to make such a compensation. Then, again, when a lessor is proceeding to enforce a right of re-entry or forfeiture, the Court before which the case comes may refuse or grant relief to the lessee, and may do so upon such terms as it thinks fit. These sections, in short, give the Court a general power of discretion in dealing with cases of forfeiture, such as have long been wanting, though it has been demanded by law and other reformers. But these clauses are not to affect the right of forfeiture for breach of a covenant not to assign, underlet, or part with the possession of premises, which, therefore, remains of the same absolute legal effect as before; and as against which there is still no relief if the lessor insists on his legal rights. Neither does the Act in any way affect the law relating to re-entry for non-payment of

rent, upon which is based the lessor's or landlord's right of ejecting a tenant who is in arrear. But it must be borne in mind that all these clauses relate to leases made either before or after the passing of the Act, and shall have effect notwithstanding any stipulation to the contrary. The result is that all existing leases, old and new, come within the provision of the last statute, and that by no means can the parties to any future lease contract themselves out of its provisions.

The broad subject of mortgages is dealt with in some important particulars by the new Act, a few of which only can we here touch upon. At present a mortgagor has no power to compel the mortgagee to give him inspection of the title-deeds. For the future this is to be altered, and a mortgagor will be entitled, at his own cost, and on payment of the mortgagee's costs, to inspect, and make copies of, or extracts from, any of the title-deeds to the property. Again, by what is known as the power to consolidate, a mortgagee having several mortgages from the same mortgagor, can refuse to allow one to be redeemed until all are satisfied. By the new Act this very great privilege is restricted, and a mortgagor wishing to redeem one of several properties, is to be able to do so separately from the others, by which the old doctrine of consolidation of mortgage will be greatly cut down, to the general benefit of purchasers and all who are concerned in the freer transfer of landed property.

We are compelled to pass over a vast number of clauses of great and varied interest to the profession, and of much importance to everyone, in so far as they tend to simplify the practice of conveyancing, but which could not here be briefly explained. There are several sections dealing with what is termed a statutory mortgage, and which may become of great practical importance as being based upon a simpler system than that now in use. The Act itself contains a schedule of forms, which are certainly short enough, though to what extent they will be adopted, time alone can tell. There are also other forms of Deeds of Mortgage, Further Charge, Conveyance on Sale, and Marriage Settlement that seem to contain all that need not be set out in writing. But here, again, the question arises, Will they be used by the profession or the public? It must not be forgotten that the same experiment has often been tried before, though with little success, the whole practice of conveyancing being in the hands of those who are most conservative in their habits and modes of thought. Neither ought we to overlook the fact that it is often easier to draw a long deed containing all usual clauses, and providing for every possibility, than to set out only what is really needed, for this latter requires a wide knowledge of the real property statutes. For the rest, the new Act is a step in the right direction, but its success will be found mainly to depend upon the way in which solicitors' costs and charges are dealt with under the recent statute passed for that purpose.

FIRES IN PUBLIC BUILDINGS.

THE terrible calamity which has befallen the people of Vienna, and which has converted a large theatre into a furnace of human victims, has been the means of calling out a variety of suggestions for the security of our places of amusement, which may be worth an attentive ear at this festive season. Three correspondents have addressed us on the subject, and numerous hints have been given in the public press. Much as the authorities in the Vienna catastrophe were to blame for remissness, we have to consider the chances of successful administration at the moment of a panic. All is confusion,

and the best regulations are rendered perfectly imperative. The recent inquiry undertaken by the *Préfet de Police*, Paris, and the report submitted to the Minister of Public Instruction on the regulations to be carried out by managers and proprietors of theatres, are worth the attention of all connected with buildings of the class we are now referring to. We have on previous occasions referred to the rules laid down by the Board of Works and the Lord Chamberlain respecting the area of buildings intended for public assemblies, their isolation from others, and other internal arrangements. These points have been made the subject of inquiry by the French Commission, and are worth mention. In the case of old theatres, there is a difficulty in securing separation of the theatre from adjacent buildings, and the suggestion that an independent brick wall be added to the theatre to protect the party-walls of houses is a good one. Separation also by thick walls of the stage, auditorium, and administrative offices is insisted upon, as well as the total isolation of all store-rooms from the part occupied by the audience. A very useful suggestion is that balconies for the use of firemen be erected above the stage, and commanding it so that they should have control over the combustible apparatus and scenery. The employment of an iron curtain suspended by combustible cords, which would fall when a fire broke out, may be adopted without much hesitation. The curtains used in Paris are of trellis-work in an iron frame, or of a metallic gauze with a small mesh. This gauze is made so as to stop the passage of flame, and some improved curtains have stout iron wire trellises on both sides of the fine gauze to protect it, so that the curtain is made up of three thicknesses. Yet these open curtains have certain serious objections: They allow the fire to be seen through them by the spectators in the auditorium, causing panic; they allow air to feed the flames and smoke to pass through. In many Continental theatres the curtains are made of sheet-iron, the sheets being hinged together, which secure all the advantages of shutting out the fire from the eyes of the spectators, separating in a more air-tight manner the stage from the auditorium, and effectually shutting off the smoke. The curtains can be raised by hydraulic power, and counter-balanced by weights.

With regard to the question of lighting, the subject is yet in too uncertain a state to admit of a solution of all the difficulties in the way. The lighting of theatres, especially the stage, is a complex matter. The "flies" and scenery have to be lighted so as to be capable of being modified, sudden transformations have to be produced, and movable gas-burners become necessary. The importance of having a separate meter for the main divisions of a theatre cannot be doubted, and the recent order of the Lord Chamberlain will add to the safety of many London theatres. The Report of the French Commission enforces a similar precaution, and to insure sufficient light in the auditorium in case of a sudden extinction of the light of the chandelier, oil-lamps accessible to the public are to be provided; the use of iron instead of lead pipes is another condition required which, however, may not be found of great service, as the defects of pipes and escape of gas generally occur at the joints. The employment of some means of movable lights; the use of improved floats protected by an outer covering, and of regulations to insure steadiness of the jets of the burners, are matters which should receive the attention of all proprietors and managers. The recommendations we have been discussing have also in view the introduction of electric lighting. The isolation of all wires for the transmission of the electric current and their protection by casing, and

the adoption of some method to prevent the fall of the incandescent carbon, are referred to in the report of the *Préfet de la Seine*.

In the planning of corridors and entrances architects have a distinct means of reducing the effects of a panic, and some of these we have pointed out in previous articles. Capt. Shaw's little book, "*Fires in Theatres*," furnish useful hints in providing the necessary areas for corridors, staircases, and gangways. But the hint thrown out by Mr. Brade, F.R.I.B.A., in our last issue is rather at variance with existing notions upon the desirability of wide passages and staircases. Mr. Brade says, and to some extent with justice, the "wider the passages the greater is the crowd, and the greater the danger;" in fact, the gist of the remark is that by increasing the width we increase the "momentum of the rush." If a number of people find a wide open passage in such an emergency they will all rush to get into it, whereas a narrow gangway can only be occupied by one at a time. By keeping the audience in single file danger is avoided, and our correspondent accordingly suggests that every passage and staircase should be divided into parallel gangways of about 2ft. wide, by substantial barriers along them so as to allow only one person to pass at a time. We believe there is a good deal in thus limiting to a given unit the entrances. By giving every individual a means of entering one of these gangways, and of preserving the line, the chance of confusion is obviated; but there is the rush and sudden impulse of panic to fear, the breaking down of these artificial barriers, and the anxiety to move quicker than the single file would permit. If we could discipline our assemblies like bodies of troops, the plan proposed would be effectual; at any rate, the idea uppermost in the mind of every spectator that he would have to fall into line in a certain prepared course, would tend to lessen the chances of being driven into wild panic and despair by not seeing a distinct passage of exit. The suggestion made by another correspondent, of having iron tubing fixed in the angles and walls of stage and auditorium, with roses for the discharge of water, is one that has been partially carried out in some theatres. The ill-directed and promiscuous cold water shower-baths, to which the terrified audience might be exposed, would, we fear, rather increase than quell the excitement of a panic-stricken assembly, and to be of any use, the water should be made to play on that part of the stage or building where a fire existed, and on no other; to do which a number of taps would be required in, possibly, inaccessible parts of the interior.

THE WATER QUESTION.—XXIII.

CONDUITS.

WATER may be very well conveyed along a hillside in an earthenware pipe, in moderate quantities. A 24in. pipe running half full, with an inclination of 5ft. in a mile, will carry a million-and-a-half gallons a day, and 2½ millions when running two-thirds full. But to go to a smaller size, a 12in. pipe with the same inclination would carry 300,000 gallons a day, half full, and 450,000 gallons if running two-thirds full. A 27in. pipe will carry, at the two degrees of fullness mentioned, 2,300,000 gallons, and 3,400,000 gallons, respectively. A 30in. pipe, nearly 3 million gallons a day half-full, and 4½ millions if running two-thirds full. The carrying capacity of any circular pipe may be found for any degree of fullness from the following considerations. If full, or half-full, the hydraulic mean depth is half the radius. This is evident, because the cross sectional area of the pipe is equal to that of a triangle, the base of which is equal in length to the circumference of the circle, and the

height to the radius, half of which, multiplied into its base, is the area. The hydraulic mean depth is the area divided by the whole circumference when the pipe is running full of water, and is, therefore, half the radius; and it is the same when the pipe is running half-full, for, in that case, it is half the area divided by half the circumference; but, at any height, H , above or below the centre of the pipe, it is as follows— D representing the diameter, and R the radius:—The width at the surface of the water (see Fig. 1) is $W = \sqrt{R^2 - H^2} \times 2$.

The width V is $\frac{D - W}{2}$. From H and V find the length of that part of the circumference in contact with the water above the centre of the pipe, and add it to the lower half of the circumference, thus procuring the wetted border of the section. The length of the two arcs above the centre is the same as that of a single arc the chord of which is $2H$. Find the chord of half the arc = $\sqrt{H^2 + V^2} = C$. Then $\frac{8C - 2H}{3} =$ the length of the two arcs above the centre, to be added to that of the lower half of the pipe, to find the wetted border, which, being multiplied into half the radius, gives an area, to which is to be added $W \times \frac{H}{2}$ for the whole sectional area of the stream, and this divided by the wetted border gives its hydraulic mean depth.

For example, in a pipe 24in. diameter running two-thirds full, the height, H , is 4in., and the width $W = \sqrt{12^2 - 4^2} \times 2 = 22.62$. The width V is $\frac{24 - 22.62}{2} = .69$. The chord of an arc above the centre is $C = \sqrt{4^2 + .69^2} = 4.05$. The length of the two arcs is $\frac{8 \times 4.05 - 2 \times 4}{3} = 8.13$. The lower half of the circumference of the pipe is $\frac{3.1416 \times 24}{2} = 37.70$, and $37.70 + 8.13 = 45.83$ in. = 3.82ft., the wetted border. The sectional area is $45.83 \times 6 + \frac{22.62 \times 4}{2} = 320$ sq. in. = 2.22 sq. ft., and the hydraulic depth, or mean radius, is $\frac{2.22}{3.82} = .58$ ft.

If Eytelwein's rule be adopted, in which h represents the hydraulic mean depth, and f twice the fall per mile, the mean velocity of the stream of water would be $\frac{10}{11} \sqrt{hf}$ = $\frac{10}{11} \sqrt{.58 \times 10} = 2.18$ ft. per second, or 130ft. per minute, and the area being 2.22 sq. ft., the quantity is 288 cubic feet per minute, or 2,592,000 gallons per day, as before stated.

Larger pipes than those of about 24in. diameter are difficult to handle, require heavy tackle to lift about, and are liable to split longitudinally with external pressure, unless the pipes are evenly bedded all round the lower half, and the haunches of the top solidly filled in between the pipe and the sides of the trench.

At what diameter, exactly, a brick or stone conduit becomes cheaper than a pipe, depends upon the local materials; but, usually, about 20in. becomes the turning-point, in respect of expense, between an earthenware pipe and a culvert of masonry. The pipe has some advantage in being glazed, but for clear water this is not of much importance. A circular conduit, 2ft. diameter and half a brick thick, would usually be laid at less expense than a pipe of the same size. Very excellent conduits are made of square shape, with flag bottom and covers, and sides of clean bedded stones with squared joints. A larger quantity of materials is required for this form than for

a circular one, because, to carry the same volume of water at the same inclination, a larger sectional area is required, and the walls, being straight, need to be thicker.

The question arises, when considering the advisability of adopting a square or a circular form, what are the comparative carrying capacities of the two forms, the more immediate question being what dimensions of the square form carry the same quantity of water per day or per minute, as a circular conduit of given diameter. This may be seen from the following considerations:—In rectangular channels the best proportion of width to depth of the stream of water is width 2, depth 1. That proportion is the best which gives the greatest hydraulic mean depth with a given quantity of materials used in the construction of the channel, because, the greater that depth, the less need be the sectional area of the stream, the carrying capacity of all conduits having the same inclination being as the area multiplied into the square root of the hydraulic mean depth. A rectangular conduit may be compared with a circular one in the following manner:—Let them both run half full; then, if the height of the rectangular conduit be the same as its width, the width of the stream will be twice its depth. Let h represent the hydraulic mean depth, as before, W the width, and D the depth of the stream (see Fig. 2). If the width be twice the depth, the area is $2 D^2$, and $h = \frac{2 D^2}{W + 2 D} = \frac{2 D^2}{4 D} = \frac{1}{2} D$; that is, in a rectangular stream in which the width is twice the depth, the hydraulic mean depth is half the simple depth, as, in the circular form, it is half the radius. Then $\sqrt{h} = \sqrt{\frac{1}{2} D} = \cdot 707 \sqrt{D}$.

The sectional area multiplied into the square root of the hydraulic mean depth thus becomes $2 D^2 \times \cdot 707 \sqrt{D} = 1\cdot 41 \sqrt{D^3}$, and this quantity must be the same in the square as in the circular form, to satisfy the conditions.

For example, in the case of a rectangular stream, in which the width is twice the depth, what would be the dimensions to make the carrying capacity equal to that of a circular conduit 3ft. diameter running half full? In this latter form the hydraulic mean depth or mean radius is $\cdot 75$ ft. The area of the lower half of the conduit is $\frac{3\cdot 1416 \times 3 \times \cdot 75}{2} = 3\cdot 53$ sq. ft., and the area multiplied into the square root of the hydraulic mean depth is $A \times \sqrt{h} = 3\cdot 53 \times \cdot 866 = 3\cdot 05$. Then in the rectangular channel $A \times \sqrt{h} = 1\cdot 41 \sqrt{D^3} = 3\cdot 05$. $D^3 = \left(\frac{3\cdot 05}{1\cdot 41}\right)^2 = 4\cdot 66$, and $D = \sqrt[3]{4\cdot 66} = 1\cdot 36$ ft., the depth, and the width is 2\cdot 72ft., the area being 3\cdot 70 sq. ft. The border is $W + 2 D = 5\cdot 44$ ft., and the hydraulic mean depth is $\frac{3\cdot 70}{5\cdot 44} = \cdot 68$ ft., being half the depth, as before stated. If the quantities of water carried by the two conduits be calculated from these data, they should be the same.

Small conduits are more liable to freeze than large ones, and should be covered, to protect them from freezing as well as from dirt. Snow is troublesome in an open conduit, whether large or small; it clogs the run of water; but the freezing over of the surface of a large body of water is not of so much importance as in a small one. In either case it reduces the sectional area of the stream, and at the same time increases the solid surface with which the water runs in contact, but the effect of this in reducing the quantity of water carried is but little in a large conduit, while it is very considerable in a small one. In respect of protection from

dirt, fencing may be sufficient in the open country, but the expense of fencing bears a greater proportion to the whole expense in a small than in a large conduit, and is almost as much as that of covering a small conduit. If the line of conduit is not subject to contamination by dirt it may be open, though it be not large, if the inclination is sufficient to cause a velocity of about 3ft. per second. This would wash away earth if not protected by a facing.

In an open conduit cut with side slopes at which the ground will stand without slipping, so that the facing is for the purpose of protecting the earth from the wash of water rather than for keeping it up by its weight or lateral resistance, the side slopes would usually be flatter than those which coincide with the best form in respect of carrying capacity. They would usually be $1\frac{1}{2}$ to 1 or more, but side slopes of $1\frac{1}{2}$ to 1 are best in respect of carrying capacity, which, with these slopes, is the same as that of a rectangular channel of a width equal to twice its depth, and of the same sectional area. The peculiarity of this slope is that the length of the two slopes and bottom is the same as the length of the two sides and bottom of a rectangular channel of the proportions mentioned, the area of the two forms being the same; consequently the hydraulic mean depth is the same, and, therefore, the discharging capacity. If the slope be drawn through the point M in Fig. 2, it will leave the area of the section the

same as that of the rectangular channel, whatever the slope be, but there is only one slope which will leave the length of border the same as that of the rectangular channel; that slope is $1\frac{1}{2}$ to 1, and the length of the two slopes is equal to the top width, being $3\frac{1}{2}$ times the depth, the bottom width being $\frac{2}{3}$ of the depth. Referring to the figure, the area is $\frac{3\frac{1}{2} D + \frac{2}{3} D}{2} \times D = 2 D^2$, and the border is $1\frac{1}{2} D + \frac{2}{3} D + 1\frac{1}{2} D = 4 D$. Hence, the hydraulic mean depth is $\frac{2 D^2}{4 D} = \frac{1}{2} D$, the same as that of the rectangular channel, and also of the circular one.

But sometimes practical considerations have greater weight than the best deductions, and the sides of an open channel would generally be less troublesome to keep up with slopes of $1\frac{1}{2}$ to 1 or more. Frost is the great disturber of the upper part of open channels, whether large or small, although the covering of water prevents it from reaching the bottom. The sides above the water should be porous—the facing, that is to say, should not be close-jointed—so that water may not accumulate behind it, for when it does so, it swells when frozen and disturbs the facing. But when the facing is thus open-jointed it would be the means of introducing mud into the conduit from behind it in long-continued rains upon clayey ground;

to prevent this, the facing should be laid upon a bed of sand.

Through loose ground the making of the conduit watertight must always be one of the chief difficulties—a difficulty of course to be overcome. For this purpose puddle, to be used with all materials except concrete, is perhaps the least expensive material, and gravel puddle is better for the purpose than clay puddle. A foot is an abundant thickness for small conduits, and if well made, 8in. ought to be a sufficient thickness for the bottom and slopes of the ground, and 2ft. above-ground in the embanked portions of the line of conduit. In these the hardest of the excavated earth will be placed along the central portion, and brought up to the level of the underside of the puddling, as far as the height above-ground is but a few feet. Probably the best material for conduits is concrete, made with Portland cement of good quality. It forms at once a watertight channel and one which needs but little protection of the surface, a facing of cement being sufficient for all that part under water, but above the water, in an open conduit, it would be preferable to face the concrete with brick or stone, and indeed for some little depth below the water surface. A covered conduit may equally well be made with concrete, both bottom and top, and the thickness need not be more than about half as much more as would be the proper thickness of brickwork.

Beyond the several points in a long line of conduit at which slight cutting should end, or the height above-ground would be but a few feet, and where it would be economical to cross straight over low ground rather than extend the line far up the hollow and back again on the other side; the aqueduct is best carried on piers and arches, but economy points to girders, which can be made to carry the water between them on a floor laid upon the lower flanges, or in the form of a wide box-girder; but if the water runs in contact with the iron the conducting property of the metal quickly draws heat from the water in winter. If it be lined with a non-conducting material, which is at the same time brittle, the difference in the rate of expansion by heat of the metal and the lining tends to destroy the adhesion. This may in some measure be prevented, and perhaps entirely, by sinking the aqueduct bodily as far as is necessary to completely immerse it, so that it may preserve a nearly uniform temperature both top and bottom; but this, of course, somewhat adds to the retardation of the floor by increasing the wetted border. To prevent contact with the metal altogether, by substituting an independent carrier for the water within and clear of the girders, would be expensive, but such a carrier might very well be made in earthenware, either rectangular or circular, and of any size by being jointed crosswise. The least expensive aqueduct would be an earthenware pipe—of stoneware or fireclay—carried on a single girder in saddles upon the top flange. An open girder, continuous over the piers, with wide flanges both top and bottom, would resist the wind, and as the pipe and the water together would be of considerable weight, it would not be likely to be blown off the girder, especially if tied down with a strap over all, every 10ft. or so.

LIFE AND WORKS OF MICHEL ANGELO.*

AN interesting volume on the life and works of this great Italian master, compiled chiefly from the unedited documents preserved in the Buonarrotti archives and from the Life of Michel Angelo written by

* Life and Works of Michel Angelo. By CHARLES HEATH WILSON, K.C.I. 2nd edition. London: John Murray.

Commentatore Gotti, has been brought out by Mr. John Murray, the author being Mr. Charles Heath Wilson, K.C.I. The second edition of this work is now upon a noble, and is illustrated by drawings of sculpture and descriptions of the frescoes of the Sistine chapel, which have been carefully examined by the author. The drawings have been executed by Signor Filippo Leonardi, and reproduced by Signori Pietro Smarini & Co., and the whole of the letter-press printing has been the work of Italians. Mr. Wilson acknowledges his indebtedness to the Commendatore Aurelio Gotti for the courtesy of being allowed to retain the documents which, as the director of the Royal Galleries and Museums of Florence, he had selected for his own work; and in presenting those unpublished documents in an English garb, the volume of Mr. Wilson is enhanced greatly in value and interest. The author had rare opportunities afforded him for closely examining the frescoes of the vault of the Sistine chapel, and a movable scaffold 5ft. in height was erected for his purpose. It is satisfactory to know that recent restoration, carried on during the late Pope's life, has preserved the frescoes from further maltreatment, to which they had been exposed, not by enemies or revolutionary mobs, so much, as from the Sacristan spirit, the clumsy and ignorant church officials and decorators. It is a well-known fact, that much of the fresco of the Last Judgment has been scratched and obliterated by ladders placed against it to erect clumsy and gaudy decorations for modern ceremonies, and even nails have been driven into the painting. We are glad to find the author speaking out freely on this spirit of modern destructive decoration. "The love of altar illumination, so wide spread in Italy, has done more to destroy pictures of every description than any other cause whatever," says the author. Again, we are told, "The frescoes of the Sistine, like those in many other chapels, are so darkened by the effects of the smoke of tapers, that, seen from the floor, the real colours are imperceptible. The veil of soot has been increased, it is said, by the burning of documents connected with each conclave, so that every election of Pontiff, since the death of Julius, if the custom is so old, has contributed to the obscuration of these great works." Cobwebs hang from the ceiling, and numerous cracks of the plaster, filled with dust and dirt, show a want of stability in the brick vault. Portions of the plaster have even given way, and one of the figures on the cornice has disappeared.

So much incidentally; we must now glance at the volume and its plan. The birth, parentage, and education of Michel Angelo form the subject of the first chapter, here the author quotes many interesting documents, such as the register of the birth of the great artist made by his father, Ludovico, who was podestà or chief magistrate of Caprese at that period, as well as a letter written to Michel Angelo in 1520, by Alexander, Count of Camossa, showing the family relationship to the noble line of Camossa. The father, Ludovico di Leonardo Buonarroti Simone, was poor when his son, Michel Angelo, was born. The memorandum of apprenticeship, made by Ludovico, when his son was placed with Dominico and David Ghirlandino for three years to learn painting is instructive as recording the early training of the great artist received, and the fact that he had already attained some progress in drawing, a compensation for which his masters paid him the first year of his apprenticeship "six golden florins," according to agreement. Several anecdotes are told by Vasari, showing the rapid progress made by the youthful student. The frescoes in the choir of Sta. Maria Novella, executed by Ghirlandino, were painted during the first year of Michel Angelo's apprenticeship, so it

was not to be wondered that he made early acquaintance with the technical processes of an art in which he attained such eminence. The preparation of the lime, the laying on of the coats of plaster, the grinding of colours, and the enlarging and drawing of cartoons fell to his share, as well, no doubt, as some of the decorative portions of the frescoes.

The youthful pupil is said to have, at one time corrected the outline of one of his masters' sketches; and it appears he sometimes excited the jealousy and anger of his instructors. His talent with the pen and crayon is pointed to as one of the neglected studies of the present day, and those who had the good fortune of seeing the exquisite pen and chalk sketches by the old masters in the Grosvenor Gallery sometime ago, must have noticed how important and effective a part such drawing for decorative subjects played in the work of great artists of the Italian school. Michel Angelo was soon transferred to the Academy of St. Mark, and placed under Bertoldo, who instructed him in modelling. His first work in marble was a mask of a fawn, in a Late Roman style, now in the museum at Florence. A drawing of this mask is given by the author. Lorenzo the Magnificent became struck by this work of the youth, and subsequently took him under his especial notice as an inmate of the palace, and a student of the sculpture in the Medici garden. The low relief Madonna and Child, after Donatello, is another illustration. The drapery is certainly clumsy, and the feet and hands large, and Vasari's admiration of this early work is, as the author observes, greatly exaggerated. Michel Angelo's dispute with Torregiani, which led to a blow which disfigured the great artist's nose, the death of Lorenzo, and the return of Michel Angelo to his father's house at the age of 17; his subsequent study of sculpture and anatomy, form other incidents in his early career, which Mr. Wilson recounts in a fair, though critical spirit. The young artist was not the model of amiability some biographers would make him. He was hasty and inclined to quarrel, yet he proved himself a good son and citizen; and in spite of the age and society—not the purest—in which he lived, he was unspoiled by the surroundings of Medicean luxury. So, at least, we must infer, if we accept the author's account.

We have no room here to trace other events. His connection with the Medici brought him many ill-friends and enemies, and foreseeing the danger which threatened them, he went to Bologna. Here he sculptured several statuettes, especially a figure of an angel for the altar of St. Dominic. Returning to Florence, he executed the statue of St. John, a work lately discovered in an old art-dealer's shop, a drawing of which is given.

The first visit of the great student to Rome in 1496, whither he had been invited by Cardinal San Giorgio, who had accidentally purchased a recumbent cupid by him, reputed by the dealer to have been an ancient work, is fully narrated. Michel Angelo's letter to his friend, Lorenzo, giving his impressions of the cardinal's statues, and the commission to carve a marble statue for him, add to the interest of the narrative, and throw light upon the society of the day. The chapter embraces the history of the great sculptor from this period to 1498, when he returned to Florence at the pressing request of his father, then in ill-health and poverty. The letters to his father show the filial affection of the young artist, and the harassing nature of the claims made upon him by his family on account of the deprivation of office on the expulsion of the Medici. The marble Piera was a group which brought into play the power of the sculptor, as Mr. Wilson remarks, "the taste of Michel Angelo re-

volted against the methods usual with the medieval artists of exciting feeling in agonised or emaciated forms, and we see in this group a loftier ideal of art." We skip over other of the early commissions entrusted to the artist—his execution of the colossal statue of David for the cathedral at Florence in 1501, and his invitation to Rome by Julius II., who employed him to sculpture his monument. The rough bistre sketch of this monument is reproduced, and shows a sort of podium, with pedestals and niches, &c., adorned by figures carrying a cornice and groups in two stages; the architecture being indicated in a rough manner. There is, perhaps, a lack of religious feeling in the composition which received the approval of the Pope, who provided money and instructed the artist to go to Carrara to purchase the necessary blocks of marble. After spending much time, the work was proceeded with till the Pope's sudden change of conduct induced Michel Angelo to leave Rome. The story of Bramante's perfidy in this matter is discredited, and the author thinks it more probable that the pontiff had seen the desirableness of less expenditure on works of art. The Pope's intimacy with the great sculptor led to a strong enmity between Bramante and himself, however, and this lasted during the life of the latter. Every reader of Michel Angelo's life knows of the flight of the great sculptor after this event, the sending of papal couriers after him, and his refusal to return. The letter of Michel Angelo to Giuliano explanatory of his conduct, and the letter from Pietro Rosselli as to Bramante are valuable contributions towards clearing up certain misapprehensions of his career. It is quite clear that the sculptor's confidence in Julius was shaken by the insulting treatment he had received at the Vatican; but he was wrong in his estimate, as was proved by the after reconciliation between the sculptor and the pontiff, when Julius II. ordered a statue of himself to be made in bronze at Bologna. The year 1508 was eventful in the career of the sculptor. He again settles in Florence, and is summoned to Rome by the Pope, to paint the vault of the Sistine chapel. He reluctantly undertook this work, as he considered painting was not his profession. The account given of the suspended scaffold constructed by Bramante for this purpose, and the doubt raised by Michel Angelo as to its adaptability is interesting, as it affords evidence of the skill of the great artist in construction. A new scaffolding was devised by Michel Angelo, which was a model of its kind. A detailed description is given by the author of the celebrated chapel, and the subjects painted in the compartments, comprising three hundred and forty-three figures. Those who have seen this miracle of decorative composition can alone estimate the life and action and expression of the colossal figures painted upon the vault and its pendentives. The artist's ideas were embodied first in sketches to a small scale in red or black chalk; afterwards drawings from the model were made; and finally the cartoons or working drawings were prepared. These were chiefly transferred to the plaster by "pouncing," and Mr. Wilson furnishes interesting details of the process. This part of the work is illustrated by outline sketches of the recumbent figure of Adam, which took, it is thought, only three days to paint. Outlines are also given of one of the sitting young men on the cornice, exquisite examples of powerful design and expression. The remarks on the style, drapery, light and shade, and colour of these figures, the contrast between the treatment and that of the realists, the payment of Michel Angelo, and the time occupied by him are instructive and interesting. Only twenty months were occupied in accomplishing the work, according to some biographers; but as Mr. Wilson

observes, the frescoes were not completed till 1512, and occupied nearly four years.

Another chapter describes the artist's work on the monument of Julius, and the new design during the pontificate of Leo X., his employment in the marble quarries of Carrara, and also his design for San Lorenzo. His design for the Laurentian library; the work on the tombs of the Medici; the painting of the Last Judgment; the Pauline chapel; his appointment as architect of St. Peter's; the scheme for the cupola and the model for its construction are the subjects of the concluding chapters. We cannot enter into these interesting topics. Elevations and details of the Laurentian library, and the cupola of St. Peter's, besides many illustrations of sculpture will be found in the pages of the volume. The copies of important letters bearing upon these and other commissions lend authenticity to the narrative of the author, and the work, in its scope and details, must take its place among the most reliable of biographies of this great master of one of the most eventful periods in the history of art.

THE WATER SUPPLY OF ENGLAND AND WALES.*

ONE of the most valuable contributions that have been made on the subject of water supply, and its underground circulation and surface distribution, has just been published in a bulky octavo volume, by Mr. Charles E. De Rance, Assoc. Inst. C.E., F.G.S. Mr. De Rance's qualifications for such a task as that which he has undertaken have well fitted him for it; and the statistics and data which he has obtained as secretary to the Committee of Inquiry into the underground circulation of water, appointed by the British Association of 1874, enable him to present a work fully up to the time. As our readers know, the Council of the Society of Arts in 1878 convened a Congress to consider the question of water supply, and the subject was discussed at the Society's rooms on this and the following year, when the author read papers bearing upon the questions. These and other lectures of the author, have furnished the basis of the volume now before us. The author describes all the river-basins of England and Wales, and the maps given, showing the annual rainfall in different parts of the country, the underground circulation, the catchment-basins, the growth and water supply of London, and the density of population in England and Wales, are particularly useful additions.

The rainfall has been based on Mr. G. J. Symons's returns, and the area of the chief geological formations defined, for the purpose of estimating the volume of water available. It seems certainly a matter of surprise, that although the rainfall of England exceeds 25in. per annum over the whole area west of a line drawn from Shields to Reading, and is more than 75in. per annum over a considerable part of that area, such as the Lake Districts and west part of Wales, there should be a scarcity of water in many of our cities and rural districts. Much information of value will be found in the first chapter, which treats of rainfall and the percolation of rainfall, and furnishes a number of average gaugings in the Lake districts, the Pennine chain, the millstone grits, &c. For instance, in the Loch Katrine district and in the Welsh hills round the sources of the Severn, Mr. Bateman takes 60in. as the available average of the estimated rainfall of 75in. Not less than 12in. of this would be lost by evaporation,

being a mean between 9in. and 16in., leaving a net available produce of 48in. This estimate accords with that gentleman's evidence before the Royal Commission of Water Supply—namely, that the available rainfall must be calculated on the average fall over a district for a long period of years. The amount of rainfall of course varies—the declivity and geological formation of the country, its cultivation, and amount of vegetation having much to do with the quantity. The vegetation takes up a great deal of the rainfall, and the rivers help to drain it off, and these and evaporation make from 9in. to 16in., the rocky and steeper surfaces giving the smallest quantity.

According to Mr. Bateman, the dry-weather flow of streams due to springs only amounts to one-fourth of a cubic foot to three-fourths of a foot per second from each 1,000 acres of area drained, or an average of half a foot per second for a dry season, while the volume of floods varies from 200 to 500 cubic feet per second, or 500 to 1,000 times the dry-weather flow. These figures relate to high, impermeable districts, and show the value of impounding reservoirs, which increase the useful volume of the stream by returning a large percentage of water.

Several facts, not well known, are furnished. In mountain districts the rainfall steadily increases up to an elevation of 2,000ft.; the fall is chiefly towards the side of mountain exposed to the prevailing rain-wind—thus the wet winds of the Lake districts are the dry of Northumberland. When hills rising to an elevation of 3,000ft. are breached by valleys of lower elevation than 2,000ft., the rain-clouds pass through and discharge on the lee slope of the hills, as is found to be the case at Westdale Head and Beddgelert. The gaugings of Mr. Bateman go to corroborate this phenomenon. A mean of several observations at different heights, taken along a line from south-west to north-east, show on the westerly side of hill's an increasing amount of rainfall as the elevation increases, and a less amount eastwards. These observations also have clearly shown the effect of a range of hills on rainfall in abstracting moisture. The average figures indicate an increased fall at certain heights in the vicinity of hills.

The variation of rainfall in different localities has made it difficult to determine any fixed data as to the minimum supplies of water in certain cycles of years; and greater experience is demanded before we know what part of the minimum quantity is available for gravitation waterworks. "When they are mainly dependent on springs, the winter's rain is of the most importance, and even though the year's fall may be above the average, if the winter is dry the springs will fall off, especially when two or three dry winters succeed each other." The author quotes several authorities: Mr. John Taylor, Mr. Hassard, Mr. Robt. Rawlinson, C.B., and others, in this part of his subject. "Basing calculations on average falls of rain is erroneous; the minimum quantities only should be depended on," says Mr. Taylor, and complete security against want of water can only be attained by storing all the floodwaters of two or three successive winters. Waterworks ought, therefore, to be made to supply in average years twice the quantity of water required. Large pipes for discharge are no doubt more economical, as the velocity with which water flows through a large pipe with a small fall can be made as great as that of water flowing through small pipes at a greater fall. The importance attaching to the geological conditions of a site before constructing a reservoir embankment, has been amply illustrated of late years. The banks should be carefully compacted every foot in height, as water, like the arch, "never sleeps." Outlet culverts should be built of brick or rubble with one-third of mortar,

not with hewn ashlar, as the joints are liable to leakage. Many interesting experiments and results regarding percolation of rainfall are recorded, which detail the contrivances used by various observers, also with respect to the "saturation plane" in different soils. Porous soil underlain by impermeable deposits, or by fully saturated subsoils, have the water-line a few inches or feet from the surface, while in sandstone and limestone hills intersected by valleys, the water-plane is found to be "slightly above the lowest level at which the deepest valley intersects an impermeable stratum forming the floor on which rests the water-bearing rock."

The upper Thames basin, sections of which have been made and published by Professor Prestwich, shows underground sheets of water, formed in the permeable rock between impermeable strata, these having a "dip" and alternating with the porous ones. The author alludes to other well-known phenomena, more particularly the difference between the rest-level and the pumping-level of wells; the capillary attraction exerted by grains of sand in sandstone and grits; the amount of absorption of various stones; the filtration of sea-water through sandstone; the storage capacity of given thicknesses of rock, and other data of much value. It is useful to know that 1in. of rainfall equals one gallon falling over two square feet, or 22,427 gallons per acre, and during a whole year such a rainfall gives a daily average of 62 gallons per day per acre, or 40,000 gallons per square mile. The remarks on the effect of drainage, and its effect in lowering the outfall; the composition of rain-water; filtration of Thames-water; and the tables of analyses, &c., are exhaustive of recent researches in these directions. It is stated, on the authority of Dr. Frankland, that the water from the lakes of Thirlmere, Hawes-water, and Ulleswater contains not more than 0.194 in 100,000 of organic carbon.

The great river-basins are described with much detail, and occupy the bulk of the volume. Beginning with the river-basins of the north-east of England, the great central watershed separating the Severn, Dee, Mersey, Ribble, and Lake district streams from the Humber, the Tees, and the Tyne, is noticed. This watershed hugs the western coast. The geological structure is the chief clue in making a division of basins. It is found, indeed, that the direction of these watersheds is governed mainly by geological peculiarities, such as tilt or dip of strata, the anticlinal and synclinal curves in the rocks produced by subsidence and elevation. The river-basins are separately considered, with the area of each, the towns and tributaries belonging to them; the particulars are given from the Ordnance Survey. The basins of the Humber, the Wash, the Thames, and east-coast streams, the south-coast streams, the South Cornish basin, the Devon basin, the Severn and West Wales basins are all detailed in this manner, and, to facilitate reference, the main rivers are printed in italic capitals and the tributaries in small italics. All the urban sanitary authorities are also clearly distinguished by small capitals, and under each we find the acreage, number of inhabitants, the source of supply, daily quantity, the means of storage, filtration, &c. The geological formation of each basin is minutely detailed, thus furnishing to the engineer engaged in the construction of new waterworks essential data only afforded by a variety of otherwise inaccessible publications and papers.

Speaking of the Thames basin, the author points out, the central anticlinal axis of the so-called Weald Valley defines the southern limit. To the west the watershed runs from Selborne to Marlborough, along a line coinciding (the author observes) "with the axis of movement that has thrust into sight the

* The Water Supply of England and Wales: its Geology, Underground Circulation, &c. By CHARLES E. DE RANCE, Assoc. Inst. C.E., F.G.S., &c. London: E. Stanford, Charing Cross.

greensands of the vale of Pewsey; and it is worthy of note that this natural line closely corresponds to the boundary between the counties of Berks, Surrey, and Kent on the one side, and Wilts, Hants, and Sussex on the other—a fact of importance to those who are anxious that watershed areas should be as far as possible coincident with County Boards in any scheme of national water supply."

We may add the Thames basin includes 170 square miles of lias; 231 of oolites; 5 of Hastings sand; 13 of would clay; 453 of greensand and gault; 2,096 of chalk, and 915 of tertiary deposits. The map given of the metropolis, showing the areas built upon at different dates from 1560 to 1881 is interesting as indicating the rapid growth from 1867 to 1881. Another map defines in colour the boundaries of the water companies supplies, or the superintendent registrars' districts. Those interested in the London water supply, and all who are engaged in works of supply; officials of urban sanitary authorities, and students of hydrogeology, will find Mr. De launce's work a valuable aid. The statistics are compiled from the most reliable sources.

ST. ALBAN'S ABBEY.

TAKING the world's history as our guide, the conquering legions of Rome after landing from Gaul on what we now know as the coast of Sussex, advanced northwards until the whole island was subjugated. About 20 miles north of the river Thames they founded a city, on the ruins of a British town called Verulam, which was composed of rude huts and sheds, protected by palisades and a ditch, and after they had brought the people under subjection they conferred upon this place the term of dignity, "municipium." The late Dr. Nicholson states "When Aulus Plautius first commanded in Britain (A.D. 42) Verulam had the pre-eminence of a municipium conferred upon it; the native inhabitants enjoying the rights and privileges of office and government of law and property, equally with the Romans themselves. By the way, I will mention that this honour was enjoyed by the citizens of Verulam before it was conferred on those of Londinium, the modern London; Eboracum, or York, being the only city having a similar privilege. The fidelity of the inhabitants of Verulam to the services and interests of the Romans brought upon them the anger of Boadicea, Queen of the Iceni, who A.D. 61 avenged the bitter wrongs of herself and her people by the slaughter of many thousands, Romans and Britons indiscriminately. Dion Cassius writes that 70,000 were hanged, crucified, or cut to pieces without mercy." The city was soon afterwards retaken by the Romans with great slaughter to the Britons. It is also a matter of accepted history that the Christian faith continued to gain ground until the time when its maintainers throughout the Empire suffered dreadful persecution under the edict of Diocletian A.D. 303, when there was great persecution of Christian people, and in this same time St. Alban was martyred. The St. Alban's Chronicle, a MS. in the Archbishop's Library in Lambeth Palace, makes mention of this. There can be little doubt that the story of the martyrdom of St. Alban had become enmeshed with much that is "imaginative" before it assumed the complete form in which we find it recorded by Bede. The first mention of the martyr is in the life of St. Germanus of Auxerre, written by Constantius at least 150 years after the date assigned for the death of St. Alban. It is clear, too, that when Offa II., King of Mercia, founded his church here about A.D. 793, the exact place of the martyr's tomb was forgotten. Gildas, the Ven. Bede, and Matthew of Westminster concur in the fact that a church was founded in honour of Alban on the spot where he suffered, within a very few years after the martyrdom. Bede states that the church was existing in his day A.D. 731. The story of Offa's foundation leads us somewhat into the region of the marvellous, but we cannot reject altogether the account in Bede. The evidence for the ex-

istence and martyrdom of St. Alban is tolerably sound, and we may claim him, not indeed as the "Protomartyr Anglorum," since the Angli were not yet in sight, but as the first recorded sufferer for the Christian faith on the soil of Britain. Where his relics really repose is quite uncertain. The remains preserved in the great shrine were possibly his, if we believe the story of the discovery of his coffin by Offa. Probably they have mingled with the dust of the hill on which he suffered and on which his great church rises. There is a shrine to the honour and in memory of St. Alban in the Schmorgasse at Cologne, where some relics are shown as those of the martyr, but their identification is a matter of doubt. Offa journeyed to Rome to obtain consent of Pope Adrian to the building and endowing the church and monastery. This was granted; together with the canonisation of the martyr, and especial privileges to the contemplated establishment. The Peter's pence which had been originally levied in A.D. 727 for the maintenance of a Saxon college in Rome, were appropriated to the Abbey of St. Alban. It is believed that Offa did not complete his purpose of constructing a larger and nobler church, although he began to do so, but used the church then standing for the temporary deposit of the remains of the martyr. His occupation during his life was chiefly the erection of monastic buildings, leaving to Elfric, his son and successor, the duty of building the church. But the church so designed was not finished by him for we have it on record that Eadmer, 9th Saxon Abbot, collected materials for rebuilding the church which was the edifice existing at the time William the Conqueror set his foot on these shores. At that time Frederick, 13th Abbot, ruled over the monastery. He was elected in the short reign of Harold, and was of the royal blood of the Saxons, and also next heir to Canute. Dr. Nicholson remarks that he was a principal instrument in extorting an oath from William the Conqueror, which was administered by himself, that he would keep inviolate all the laws of the realm, which his predecessors, and particularly King Edward (the Confessor) had established. But the Conqueror subsequently disregarded the engagement he had made, and the Abbot was forced to retire to Ely, where he died in great vexation of heart. With the introduction of the Norman rule in England we may date the history of the present building, for after the retirement of the Saxon Abbot, Paul of Caen, kinsman of Lanfranc, Archbishop of Canterbury, was appointed in 1077 to preside over the monastery. He pulled down the Saxon building and constructed the church entirely anew of stones and tiles taken from the ancient city of Verulam, a great portion of which had been collected by the two last Saxon Abbots. Indeed the proximity of the city in ruins was just what was required, and formed a convenient quarry for the Norman structure. Built now almost entirely of Roman bricks above the foundations, from the city which stretched along the opposite hillside—the walls and tower spoke, as the latter in its renovated condition speaks with a yet clearer voice, of the days of the Cæsars, of the early struggles of the faith, and of the changes which rendered possible the use of such materials for the construction of a great Christian church. The architecture of this first portion, comprising besides the tower, that of the transepts, choir, choir-aisles, and six bays on the north side of the nave, is purely Norman of the earliest period, begun in 1077 and finished in 1088. The peculiarity of the construction is that from the shape of the Roman tiles, about 17in. by 11in., the piers and arches all have angles of 90°, no cut stone being used, except a little in the plinth, the impost and caps of the arcades, and save and except the axed-baluster piers in the triforia of the transepts, and the tower galleries. These piers are believed to be portions of the earlier church of Offa, placed in this position where they might be used and seen with advantage. On the east face of the tower triforium is a large cap worked in Purbeck marble, being the earliest use of that material that I am aware of in this country. The architecture of this first portion tells of the years immediately succeeding the Norman Conquest, when Lanfranc assisted his friend and kinsman, the Abbot Paul, in rebuilding the church, and the heads of the Benedictine Monastery were about to become great feudal lords. The Norman abbot carried his work into execution on a scale so gigantic as even now to astonish the beholder, and for the

next four centuries and a half St. Alban's ranked among the greatest of the ecclesiastical foundations in England, her abbot during the greater part of that time not only being a peer of the realm, but taking precedence of all the other mitred abbots of England, his Abbey being endowed with vast possessions and privileges; and his church the resort of numberless pilgrims who flocked thither from every quarter to do honour to the remains of the protomartyr of Britain. The church, as built by the early Norman abbots, was, as before said, of vast dimensions; as large, probably, as any abbey church or cathedral of that period, gigantic as many of them were. It was built on a beautiful symmetrical plan. The nave, or western arm of the cross, alone measured internally 285ft. in length, and the total length of the church was then about 450ft. It had no less than six apsidal chapels besides the great apse containing the high altar and the shrine of St. Alban; and its dignity externally was enhanced by three vast towers, one at the intersection of the cross and two in the western facade. The whole edifice, in its perfect and unaltered state, must have been dignified and noble in the highest degree, though (being built entirely with Roman brick, and covered both within and without with an incrustation of plaster) its beauty was the result of outline, proportion, and vastness, rather than of architectural detail. The stern severity of the interior was, however, relieved by costly accessories, and by the enrichment of every part of its surface with painted decorations, of which remains may still be traced, wherever the early surfaces remain. If the last century was a period of destruction, this is as certainly one of renovation, and the works which are now in progress at St. Alban's mark an epoch in the history of art and of the church, not less distinctly than the Roman brick and huge arches of its tower, or the shattered sculptures of its shrine. There is no English church, unless perhaps we except Canterbury, which tells so striking and so plain a story. After long years of neglect, it is "renewing its strength," and recovering its ancient beauty. It rises on its green hill above the Ver, a long "ridge" of building, a witness to the changes of 800 years; while the bricks of its tower, as the sun lights up their faces, tell the tale of yet another ten centuries. Roman Verulam, the pagan city, with its temples, its amphitheatre, and its luxurious villas, has vanished, and but a mass of crumbling wall remains on its site. The great Christian church, to build which the city was spoiled, still looks across to the gate from which St. Alban was led to his execution, and if my Lord Abbot has passed away, his chair has been raised to an episcopal see, and a Bishop of St. Alban's has succeeded, not indeed to the old magnificence of the Abbots, but to their church, and to its venerable associations. The use, in mediæval buildings, of the materials left by the ancient Romans, though carried to a greater scale in this than in any other building, is by no means unique. We find it in the Saxon churches of Brixworth and Dover; at Colechester we see it in the Saxon Church of the Holy Trinity and also in the Norman castle, and in the priory of St. Botolph; and every here and there where a Roman structure was at hand we see its well-burnt tiles doing duty in the existing church. I have already described what remains to our own day of the work of Abbot Paul: its stern character, majestic in its scale and proportions, but devoid of any approach to decoration. The next piece of work which we have succeeding the Early Norman, is that of the slype or leontory on the south side of the south transept. This is also Norman, of a more ornate character, with capitals exquisitely and delicately carved. The Abbey records state that this slype, as well as the Chapter House, which stood on the south of it, was built by Robert de Gorham, 18th Abbot, in the reigns of King Stephen and Henry II. He granted lands in the neighbourhood to one of his family and name, who settled there; and the place obtained the appellation of *Gorhambury*, i.e., the house and dwelling of Gorham. King Stephen was honourably entertained by this Abbot, who profited by the occasion to obtain permission to demolish all that remained of the royal place of Kingsbury, because certain of the royal servants, who gave much annoyance to the Abbot, occupied a tower towards the east, almost in the centre of the street, as a residence and refuge. This palace had been bought by Elfric, 11th Saxon

Abbot, of King Ethelred, and was all destroyed by that abbot, except the tower before-mentioned, in the reign of Canute, who would not permit all the buildings to be razed to the ground, because that some vestige might remain of the royal residence, together with the name, which still survives after the lapse of so many centuries. The position of St. Alban's Abbey on the line of the Watling-street, the great road which crossed the country from Kent to Chester, together with its convenient distance from London, gave it a special, and sometimes undesired, importance, as a resting-place for Kings and great personages travelling northward, and as a sort of outpost of the metropolis. It grew, as we know, into one of the wealthiest Benedictine houses in London, and if its resources were sometimes drawn upon after a fashion which provoked an outcry from the monks, the general hospitality of the Abbey was unbounded. Prelates from far countries, such as that Armenian Archbishop, who told to the brethren the story of "The Wandering Jew"; monks of other orders, such as those from Clugny, who at Abbot Wheathampstead's expressed desire, left with him a pattern of the habit worn by them; great lords and bishops, with their train of attendants, their horses and their dogs; and great foreign princes, who after kneeling at the Canterbury shrine, seldom failed to visit that of St. Alban, were all welcomed, and all received the lodging and the entertainment due to their several conditions. The great tower and the vast church are nowhere more impressive than when approached from the side of London, and the view from the last steep ridge over which the road passes, where the Abbey suddenly presents itself, projected against the sky beyond a wide wooded landscape is much the same (allowing for the difference between a well-kept road and a rough track through the old forest of Hertfordshire) as must have been looked on by those earlier pilgrims. Such an abbey must have been the pleasantest of hostleries. It well maintained those old Benedictine traditions of hospitality and learning which gave strength to the order in the dark days of the last century, and in our own time have preserved to it, in part, at least, its primitive cradle at Monte Cassino. The next work in point of date is the lower portion of the west end. You are all aware of the position of the great western porch, but I am confident that many here assembled were not aware that there had existed years ago two other entrances in the west front, to the north and south aisles of the nave respectively. About 150 years ago, as I believe, speaking more accurately, in the year 1722, when much repair was done to the Abbey, these porches were from some cause blocked up in the outside; the blocking material being the moulded and carved fragments of the parts of the porches themselves, nearly one half of each porch being rudely shaven down for that purpose. These three porches were begun to be erected by Abbot John de Cella in the reign of King John (about the year 1195), a prelate of more taste than worldly wisdom, who conceived the ambitious idea of rebuilding the whole western front with its flanking towers in the rich Early English architecture of the period. The historian, Matthew Paris, amusingly dwells on the misfortunes and disappointments of this over-sanguine Abbot, arising as he states "from his attending but little to that admonition of which mention is made in the Gospel, that is to say, 'He who is about to build should compute the cost lest all begin to jest at him, saying, This man began to build and was unable to finish it.'" The preceding abbot had left him the sum of 100 marks, which had been assigned and set apart for the work of the church and the western towers. He pulled down the Norman west front, and "began to bring to the spot timber, and to provide stones, not a few, with columns and planks. He assembled a number of chosen masons of whom Master Hugh Goldelif was the chief—a deceitful but clever workman—and having dug and thrown out the bottom, in a short time the 100 marks, with many more, exclusive of daily allowances, were expended, nor as yet had the wall reached the level of its foundations. It happened by the design of the said Hugh, in addition to the stealth, fraud, impertinence, and, above all, extravagance, before the average of the work had risen to the boarded shed, the abbot grew tired, weary, and timid, and the work languished. The walls were covered up for the winter; but in consequence of the tender-

ness of the stone (from the Totternhoe quarries, near Dunstable) they became fractured, and from their thinness bulged out and ruinous, together with their columns, bases, and capitals, and fell with their own weight, so that the wreck of images and flowers became the laughing-stock of beholders. The workmen therefore quitted in despair," and the chronicler significantly adds, "nor did any wages reward their labours. Howbeit the abbot, not dismayed on that account, appointed Gilbert de Everholt guardian of the work, and contributed towards it a sheaf from every acre of sown land. And this lasted from the time from which he began to give (that is to say, the third year of his prelate) through his whole life, about 17 years, and in the life of the following abbot, about 10 years; neither did that unprosperous work ever appear to increase, nor at last was his heart indulged with the fulfilment of the wish that it might be finished in the time of Abbot John, so that he grieved inconsolably." Many devices were resorted to in order to get money of which he raised "not a little," but that unfortunate work, like the sea, swallowed up all the rivers, nor as yet had a happy advancement begun. Therefore, as the work had gone on fruitlessly in past years, and Brother Gilbert de Everholt being dead, the custody of the lifeless and languishing work devolved on Brother Gilbert de Sisseverne, who had charge of the same for about 30 years, who having spent upon it the above-named supplies, scarcely in that period added more than 2ft. to its height. These porches are the very ones which are now being extensively repaired at the expense of Sir Edmund Beckett, and by the excavations we have made in the locality we find the statement of the chronicler to be true that the Norman church and towers were built to the full extent westward of the church as it now exists, and the Early English work of Abbot John de Cella and his successor Abbot Trumpington are built on the Norman foundations, slightly added to the projection of the porch buttresses. The entire re-edification of the west front, with the towers, so grandly commenced on the site of the destroyed Norman ones in the reign of King John, was not accomplished, the work being checked when it arrived at about one-third of its height in the front, and at the time of its revival a few years later, another architect, William de Trumpington, the succeeding abbot, brought to the task genius formed in a different mould. He completed a portion of the nave, *i.e.* four bays on the north side, and five on the south—a work of great magnificence, together with the west front from the pillars of the porches upwards, but not the tower, which, like those of Westminster Abbey, were left imperfect for ages. Sir Gilbert Scott remarks:—"I doubt whether there exists in England a work so perfect in art as the half-ruined western portals of St. Alban's. I venerate the architect who designed them, who I believe was John de Cella's second architect, Gilbert de Eversholt. His work is cotemporary with two others, which are as fine as almost any in existence: the western porch at Ely, and the choir of St. Hugh, at Lincoln. All of them were the works of the earliest perfected 'Early English,' after it had thrown off the square form of the Romanesque capital; and I believe it to be also cotemporary with another of the finest English works—the sanctuary of the dependent monastery of Tyne-mouth, which, however, retains the square capital. Next to this excellent work is that of Abbot William Trumpington, who, in a more economical spirit, with more of business, but less of art, carried on the work which de Cella had relinquished in despair, completing the west front, now destroyed, and finishing five bays of the nave on the south side, and four on the north, besides many other less important parts. His works are noble specimens of Early English, though without the spiritual character which marks the works of de Cella. It is most interesting to trace out the limits and the points of junction in the works of the two abbots, and to observe the remorseless way in which the man of business cut down the details of the work of his more ambitious predecessor. Columns with bases for eight shafts reduced at the capitals to four, the marble bandings prepared for the larger number but roughly altered to suit the reduction, while the marble largely used or contemplated by the one is almost wholly omitted by the other." The architects of this period indulged in the use and excelled in the

application of Purbeck marble, which was one of the best materials that could possibly be employed in the construction of designs, of which one of the leading aims was to conceal the actual solidity of the main columns by clustering around them numerous slender shafts. There are fine examples of these columns at Boxgrove Church, Sussex, a magnificent building, the execution of the repairs of which it was my pleasure to superintend under the direction of the late Sir Gilbert Scott in 1864. Strength, combined with lightness of character, was an advance in constructive science, pressed forward with a view of giving a pictorial richness of effect, an intricate play of light and shade, and a glowing variety of detail. The union just named was formed and practised with wonderful skill towards the latter end of the twelfth century, the firmness of the pillars being so dexterously masked by the arrangement of the supplementary shafts, and their merely decorative office is at first sight scarcely recognisable. John de Cella perhaps carried the invention too far, and reserved so little actual strength for the basement of his gorgeous front that the building gave way. It had evidently been the design of both Abbots de Cella and Trumpington that inside the porches at the west end of the nave a flight of steps all across the building should be placed. We have no direct evidence of their having been fixed. "Buckler" thinks they were not, but I have discovered pavement well worn with the feet at the lower level, showing conclusively that steps must have been there to get to the floor of the nave. It is part of Sir E. Beckett's plan to restore these steps in their entirety, which will certainly add much to the dignity of the western entrance. I believe the alteration to the higher level was made in the 15th century by Abbot Whathamstead, who cut off the bottom rail of the present great western doors to suit his new arrangement. Abbot Trumpington also inserted Early English windows, since altered, in the north aisle of the nave, and also two fine windows in the south transept, which, in 1873 I opened and repaired after their having been blocked with rubble walling for centuries. The same abbot also inserted the beautiful windows (of course I speak of stonework only) in the south aisle of the choir, and it is curious to observe the effective adaptation of his pointed inner arches to the semi-circular Norman groining. He also raised a lofty lantern on the tower, and I infer from a sketch which the late Sir Gilbert Scott left at his death, that he would have reinstated this lantern had funds sufficient been provided. It was during the rule of the succeeding Abbot, John de Hertford, that it was found necessary to repair, or rebuild the east end of the church. For this purpose, in 1256, the whole of the eastern apse from the chord of the arc was pulled down, and in its place a lofty building erected with a square end—in fact, as we see it now to the eastern wall of the Saints' Chapel, in which the shrine of St. Alban's stands. Henry III. had just completed the Chapter House at Westminster, in which the principle of traceried windows had been carried out to a perfect ideal, and we cannot suppose that the first in rank among English abbeys should fall short in advancement of style of the second Abbey, only some 20 miles distant. Accordingly we find the work of John de Hertford and his immediate successors to be among the finest productions of the period. The re-constructors of these eastern portions of the Abbey seem to have commenced, not only the sanctuary of the church with the chapel which contained the shrine of St. Alban, but also the chapel east of it (through which there was a public way for three centuries prior to 1878), in which was placed the shrine of St. Amphibalus, the proto-martyr's friend, with the chapels on either side of it, and yet further eastward they commenced the Lady-chapel itself, though its completion was left to a later date. These were never perfected according to their original design, but what was done was as perfect in art as anything which its age produced. Its window tracery is carried to a high state of perfection. Its style carries us on to the last decade of the 13th century, agreeing in character with the Eleanor crosses, one of which was erected near to where the clock-tower now stands in St. Alban's. This cross was taken down in 1702. The body of Eleanor, Queen of Edward I., rested at St. Alban's in progress from Herdeby near Lincoln, where she died, to Westminster. In the year 1201 Abbot Reger

de Norton died, and his body was buried in front of the high altar, and his heart was interred in the front of the altar of St. Mary of the Four Tapers in the antechapel alluded to. In excavating during the recent repairs we found the little stone sepulchre, cylindrical in form, which contained the Abbot's heart. The sepulchre with its stone cover remains *in situ*, but in the glass case which I now produce are the fragile remains of a cover of a wooden box which contained the heart. That distinguished scholar, Sir Henry Rawlinson, on examining the inscription on the cover pronounced it to be of Kufic character, and that the word "God" was distinguishable. It is presumed that this box was a precious relic brought from the East by one who had returned from the Crusades. John de Berkhausted succeeded Roger de Norton as Abbot in 1291, and ruled until 1302. His body is buried in the presbytery under a large Purbeck slab which has an incised inscription in Norman-French. The succeeding Abbot was John de Marins, who ruled from 1302 to 1308. During his rule the magnificent marble shrine was constructed, the restored remains of which now stand on their original site in the Saints' Chapel. In his time when King Edward II. visited the Abbey, the Abbot caused the tomb and feretory of St. Alban to be removed from the place where it stood temporarily, for repairs to the church; and the marble tomb or shrine which we now see to be constructed, at a cost of 820 marks. The Lady-chapel appears again to have engaged the attention of the builder, for Abbot Hugh de Eversden, who ruled from 1308 to 1326 is said to have recommenced the work and carried it to completion. It was also during this abbacy that a great catastrophe befell the nave. In the year 1323, one day during the time of the celebration of divine services, two of the Norman piers on the south side, supporting the roof, fell with a great crash, and within an hour the roof for a length of nearly 100ft. had fallen in, and the cloisters built against the south wall shared the same fate. The work of rebuilding this portion was soon commenced, and we find that the whole was reinstated at the expiration of ten years from the time of the catastrophe. Great as must have been the havoc effected, there is compensation to us who live in these times, at least, from the fact that the re-erection of the fallen building has left to us one of the most magnificent pieces of Decorated architecture to be found in this or any other country. Five bays were rebuilt, a worthy monument to those whose exquisite taste enabled them to design so grand a structure. It is very singular that these Decorated piers which support the work of Abbot Hugh have been the first of their kind to show signs of fracture. During the past year Sir E. Beckett has caused them to be repaired at a great expense. Their failure arose from the circumstance of small stones having been used in their construction, thereby giving them no proper bond. In fact, not one stone passed absolutely through the pier or was tied to its opposite neighbour. The clunch or Tottenhoe stone is a casing only, filled with flint and rubble concrete. This has been remedied as far as practicable. Another cause of failure arose from interments having taken place between the piers, such interments necessitating on the part of the sexton the removal of all the foundations from pier to pier. With the enormous weight above it, it is a matter of surprise that a second catastrophe had not happened. Abbot Hugh was twice besieged in his abbey by the townsmen on the question of rights and privileges. They desired to be acknowledged to the king rather than to an inferior lord. His successor, the Abbot being obliged to submit to the King's writ, commanding the Abbot to place all the liberties, privileges, &c., of the same establishment as recorded in Domesday Book. During, however, the rule of the successor Abbot, Richard de Waddington, who was popular with the townsmen, surrounded their royal charter, returned all the privileges of the town, and proved that it might be considered that the Abbot Waddington was too much inclined to the town and in astronomy. His successor, Abbot de Waddington, which was the first of the south transept. The old charter of Henry VIII., speaks of the church as being in his time, and noted the decay of the church and the ruin of the walls and flow of the tide. I believe that some portions of this church are now in existence in St. Alban's. Michael de Montaigne, 20th

Abbot, repaired the cloister which had been destroyed in 1323. The remains of such so-called repairs, which amounted to reconstruction, may now be seen against the south wall of the Abbey, affording a good idea of the perfection of the Decorated work of the period. Edmund of Langley, fifth son of Edward III., born at King's Langley, was afterwards baptised by this Abbot in the royal palace there, 5th June, 1341. Philippa, the Queen, went over to St. Alban's Abbey to be churched, and her offering was a cloth of gold. Abbot Thomas de la Mare ruled from 1349 to 1396, and was a remarkable man in his time. He rebuilt the Abbey gateway, which is the building now standing, with its chambers, prisons, and dungeons. When I had charge of the repairs of this gateway in 1870, the workmen opened the crown of an arch in the north part of the building, which disclosed one of these dungeons in size about 10ft. square and 2ft. deep in the earth. In olden times this hole was approached only from the floor above, thereby making the depth some 40ft.; telling a tale of the habits and customs of our forefathers in the good old times. This abbot was in high favour with Edward III., and when Edward the Black Prince had won the battle of Poitiers in 1356, and had taken the French King, John, prisoner, the captive monarch was for a time resident in the Monastery of St. Alban's in custody of the Abbot. There is also a tradition that the King was lodged for a time at the hostelry known as the Fleur de Lis, now standing in French-row, near the Clock Tower. In the year 1381, the 4th of Richard II., the insurgents under Wat Tyler and Jack Straw threatened destruction to the Abbey. They forced the great gates and extorted charters from the Abbots. The remains of these gates are now deposited in the Abbey slype. After the insurrection, the King came in person to St. Alban's with his chief justice, by whom fifteen of the leading rioters were condemned to death, and hung outside the Abbey Gateway. The beautiful engraved brass to the memory of this Abbot, which is now placed for preservation in what is known as Abbot Wheat-hampstead's chantry, was evidently wrought during his lifetime, for a space is left for the date of his death, which has never been filled up. When I happened to be at Lübeck, in North Germany, in 1876, I saw in the Dom Kirche there, a brass, twice the size of this one of Abbot de la Mare, and after examination I became convinced that the same hand which engraved the brass in our Abbey had also executed the one then before me. I communicated with Sir Gilbert Scott in England, and he informed me that he had ascertained the artist had been lent from Bruges to execute the work, both at St. Alban's and at Lübeck. I brought home some careful engravings of this latter brass, and in comparing them with this at St. Alban's there could be no question that the information as to the artist which Sir Gilbert had received was correct. The succeeding abbot, John de la Morte, had a severe contest with the Abbot of Westminster as to his priority of seat in Parliament, and it is recorded that on one occasion, finding the latter had taken the place of honour before his arrival, he deliberately sat down in his rival's lap, thereby asserting his prior right.

TEWKESBURY ABBEY.

AT a meeting of the Restoration Committee of Tewkesbury Abbey on the 9th inst., Sir E. A. H. Lechmere, M.P., in the chair, the chairman having called attention to the allegations contained in recent letters to *The Times* as to the supposed intention of the committee to remove the present west window, it was decided to publish what had passed at meetings held in January and March last, as the best means of showing the groundlessness of these allegations, and at the same time of allaying any anxiety which might be felt by those really interested in the preservation of this well-known feature of the abbey. At the first meeting it was resolved:—

"That there being conflicting opinions on the part of the architect and members of the committee with respect to the restoration of the west front, the further consideration of the same be postponed until an opportunity arises for the architect and the committee to have a personal conference."

"Mr. Scott having attended the second meeting in March and advised the committee to confine their efforts to getting good glass, which was greatly wanted inside, and which would redeem the defects in the tracery, the committee resolved to be guided by the advice of Mr. Scott."

"While giving publicity to the only decision of the committee in reference to this particular matter, the committee desire to record their conviction that, instead of 'irremediable damage having been done by the present restorers,' as has been alleged, not only have all historical features of the building been carefully preserved, but many details of architectural and antiquarian interest brought to light during the progress of the work, which, but for the restoration, would have been unknown and undiscovered."

THE CHURCH OF ST. JOHN THE BAPTIST, BERKSWELL.

ON December 21, Mr. J. A. Cossins read a paper to the members of the archaeological section of the Birmingham and Midland Institute, on the Church of St. John the Baptist, at Berkswell. Mr. Cossins said it appeared to be probable that the present fabric of the church, though dating from the twelfth century, stood on or near the site of a much older oratory, or chapel. The known facts of early Christian settlements lent some support to this view, and the fact of the church having a crypt was of itself a strong indication of an earlier building, as there were reasons for believing that, except there was some structural motive for a crypt, they were very rarely built after the eleventh century, unless an earlier crypt had previously existed on the spot. He had formed the opinion that the tank at Berkswell was an ancient holy well, and that a chapel or oratory stood near it; and further, that the present church stands on the original site, the presence of the crypt adding much to the probability. The church was very interesting, and possessed some unusual features. The plan was the very ordinary one of a chancel, nave, north and south aisles—the north aisle having been prolonged beyond the nave to the east, probably to form a chantry chapel. There was a low square tower at the west end, which, though dating from the seventeenth century, was in its proportions and the great thickness of its walls more like a tower of the Norman period. There was a picturesque wooden south porch with a room over it, and underneath the chancel and a part of the nave a remarkably interesting, and, in some respects, singular Norman crypt. It consisted of two parts—an octagon under the nave communicating by a very fine arch with an oblong under the chancel. He had thought that the octagon part of the crypt had been an ancient baptistery. The circular or octagon plan seemed to have been a favourite one for such a structure; and if the well had been for a long time an object of reverence and perhaps of emulment, it would be natural to suppose that after open-air celebrations had ceased to be customary, they would endeavour to connect the venerated associations of the ancient well with the church. He could find no evidence in support of this conjecture. The crypt was now used as the family vault for the Eardley Wilmot family, and the north side was fitted up with slate shelves like a wine cellar, on which about a dozen coffins rested. The other remaining Norman portions of the building were the chancel and the north arcade, the south door and some small fragments of the walls of the nave. The chancel was an extremely interesting example, the half-columns serving as buttresses. Mr. Cossins exhibited an old engraving from the *Gentleman's Magazine* of 1824, showing the appearance of the church before the chancel was restored. It was apparent from this that there was a window of three lights at that time in the south side. The window now there was a modern one, but accurately copied from the old ones. The proportions of the chancel were good, and the corbel table effective, the corbels being curiously-cut grotesque heads. The openings of the eastern triplet formed an arcade in the interior. The arches were all plain throughout the church, and the capitals mostly of the scalloped kind. Those of the eastern window were carved with stiff conventional foliage, and the terminals of the labels were grotesque heads, and formed a

very good and characteristic example. The chancel-arch was plain, with a bold shaft carrying the inner order of the arch and a smaller nook shaft on the western side. The capitals had been renewed or restored, but there was no doubt of their having been scalloped like the present ones. It was probable that the church at the end of the Norman period consisted only of a chancel, nave, and north aisle of two bays; but the plan was puzzling, and the history of its successive alterations and transformations difficult to read. He considered the time of the building of the Norman parts of the church to have been during the last twenty years of Henry I., or perhaps early in the reign of Stephen, and whilst the manor was in the possession of Ralph de Mandeville. It having been given to him about that time by Henry de Newbrough, the Earl of Warwick, it was probable that he would be disposed to be liberal under the circumstances, and might have rebuilt the parish-church. Ralph was succeeded by Nigel de Amundeville, who, Dugdale believed, had his seat at Berkswell. It was likely enough that Nigel might have rebuilt the chancel and eastern part of the crypt during his residence at Berkswell. This was mere conjecture; but it was, he thought, nearly certain that the whole of the Norman parts of the church were built in the time of Ralph and Nigel. Another feature of the church in point of date was the small triplet window at the west end of the north aisle. This was very likely added in the 13th century or 14th century, possibly about 1320 or 1330. The aisle appeared to have been re-roofed about 100 years later, as the corbels to carry the principals were of the 15th century. The present roof was modern. The north aisle was of the latter part of the 15th century, and was built on a part of the foundations of the original Norman north wall. Mr. Cossins went on to refer to the peal of bells, observing that it was seldom that they found all the bells of a peal so old as those at Berkswell. There used to be in the church an oak pulpit of the 15th century, and it was much to be regretted that it had been removed and destroyed. Mr. Cossins, in conclusion, read extracts from some of the old records of the church.

The chairman, in moving a vote of thanks to Mr. Cossins for his paper, said that that gentleman had given a new interest to a church with which most of the members were more or less familiar. Mr. Cossins's paper was unrivalled in interest, unsurpassed in novelty, and would form a valuable part of the society's records.

METROPOLITAN BOARD OF WORKS.

THE weekly meeting of this board was held on Friday last, Sir J. M. Hogg, M.P., in the chair. A very numerous deputation representing the timber trade in London attended to present a memorial against the 18th clause of the proposed Amendment Bill of the board—a clause providing that no stacks of timber of wood on a timber stage more than 25ft. high shall be erected within 30ft. of any highway without the written consent of the board. Mr. A. W. Pratt, the spokesman of the deputation, declared that no accidents or injuries had yet occurred from such stacks of wood, and that the proposed clause would necessitate the removal of the trade to the outskirts of the metropolis, and would inflict much injury, not only on manufacturers, but also on artisans. The memorial was referred to the works committee.

It was agreed to lend the guardians of St. Marylebone £1,000 for works at the Southall Schools, and £4,500 for the purchase of a plot of land in Ruckham-street, facing the new workhouse infirmary.

The works committee recommended that a proposal by the Plumstead district board—for the draining of the southern portion of the parish of Eltham into the main sewer of the West Kent sewerage board in lieu of into the board's southern outfall sewer—be adopted. Sir Joseph Bazalgette, the engineer to the board, explained that this would be the more convenient and cheaper course to pursue, as the land lay very low, and was nearer to the West Kent sewer than to the board's; but objection being raised to the size of the connecting-pipes, the matter was referred back. The same committee was instructed to consider the whole question of extending the area of the board's jurisdiction. It was agreed to contribute one-half the cost,

estimated at £2,131, of an improvement in Little Chapel-street by the Westminster district board, and a similar proportion of the cost, estimated at £1,650, of a further widening of Pear-street about to be carried out by the same board.

The Building Act committee reported that they had considered a letter from Mr. Robert Walker, district surveyor of St. Martin-in-the-Fields and St. Anne, Soho, requesting the board to hold a formal inquiry with respect to certain points in connection with reports he has officially made relative to the Royal Comedy Theatre, Pantion-street, Haymarket, and the Avenue Theatre, Northumberland-avenue, and inclosing drawings showing the construction of portions of the Avenue Theatre, and copies of correspondence with the superintending architect on the subject; and, after hearing the statements of the district surveyor, the superintending architect and the assisting architect, they had arrived at the following conclusions:—

(a) That the committee regret that the examination of the Avenue Theatre by the assistant architect, on behalf of the superintending architect, on the 26th November last, was not more carefully made, and under more favourable circumstances; and the committee also regret to find that in some few particulars the statements contained in the letter of the superintending architect to the lessee of the theatre, dated 1st December instant, have required modification. (b) That, in the opinion of the committee, the district surveyor committed an indiscretion in writing to the superintending architect the letter dated the 20th November last; and that the district surveyor ought not to interfere between lessor and lessee in any case in the manner in which he did; and (c) that the committee regret the publication by the district surveyor of his letter of the 9th December instant, addressed to the superintending architect, before the board had an opportunity of inquiring into the facts; and are of opinion that this was a great impropriety on the part of the district surveyor.

And recommended that the clerk be instructed to communicate the foregoing resolutions to the district surveyor.

Mr. Deputy Saunders moved the adoption of the report. Mr. Jones complained that the committee should censure the district surveyor, an officer who simply defended himself when his conduct was unjustly impeached. Mr. G. B. Richardson strongly condemned the conduct of the district surveyor, and declared that his conduct must be characterised as unprofessional and most ungentlemanly. Mr. Freeman thought Mr. Walker was deserving of some of the censure pronounced upon him in this report; but the board should bear in mind that that which provoked him was the report of their own officer, which had turned out to be inaccurate and altogether incorrect. Mr. Fell concurred in this, adding that it took the officer only a quarter of an hour to examine the theatre in question, and to decide as to the safety of the public in respect to it. Mr. Selway said Mr. Freeman had done an officer of the board a great injustice, for that official had simply to see that the rules of the board in regard to theatres were complied with, and such an investigation could be completed in a very short time. Mr. Deputy Saunders, in replying, said that the error of the officer of the board, if it was an error, consisted in showing too great a regard for the public safety; and the report was approved.

SHORTNESS OF LIFE AMONG ARCHITECTS.

IT is only a short time ago, remarks the *Saturday Review*, that any one conversant with the artistic politics of the day would, if asked to name the architects who had in the course of the competitions, official or unofficial, which were at that time in higher favour than they have since become, taken the foremost position as competitors, if not as combatants, have undoubtedly put in the front line Digby Wyatt, Scott, Edward Barry, Burgess, Street, to name them in the order of their departure. Now all of these are dead, Scott only just an old man, and the rest in middle age. Every one of the men, in fact, over whom any real battle at that time raged has, with the exception of Mr. Waterhouse, left the scene. The *Times* attempted to sketch, with a keener eye to faults than merits, the difference between the old and the new taste in architecture by pairing off Mr. Street with Mr. D. C. Burton, who had died a few days before, aged eighty-one. The comparison might have been more telling if it had included a third architect, who died on the very day before Mr. Street, and who was, although a year older than Mr. Burton, rather the first of the new than the last of the old school.

More than forty years ago, when prominent men of the Gothic school who have since been famous and died were still unheard of, Anthony Salvin seemed destined to lead the revived school of Mediæval art. But he was rather tepid in the important matter of ecclesiastical architecture, and so, while making proof of his mastery of castellated construction at the Tower, at Windsor, at Alnwick, and in his own modern castle of Peckforton, as well as of considerable taste in country-houses, he practically became an outsider in the animated conflict of styles which has filled up the intermediate years.

There is never an effect without some cause, and it is better to seek what explanation can be given for the remarkable shortness of life among conspicuous architects than idly to lament the losses. No doubt, as the phrase goes, it is the pace which kills; but there is something more than the mere speed to account for the dangers and the casualties of the architectural race. The nature of the broken country which has to be crossed tells against safety as much as the mere speed. Some men kill themselves by over-devotion to an art, and others by over-devotion to a profession. But it is the hard and peculiar fate of an architect to be following both an art and a profession. His education in composition matches with that of a painter in painting. His education in construction matches with that of an engineer in engineering. Once he is in practice, the thought needful to marry beauty with utility in his designs is only the beginning of troubles. He has to settle his accounts with employers, who may be stingy and overreaching, exacting and capricious, ignorant and prejudiced, vain and half-instructed, with contractors too often incompetent, dishonest, or insolvent, with workmen too stupid to understand and too obstinate to obey. Add to this the wear and tear of railways, the severities of weather, and it will be seen that the career of a successful architect is one which tells with unusual severity on the human frame. Yet there is no remedy which could be thought of which would not be worse than the disease. To separate the professions of artistic and of constructive architect would be to extend and to perpetuate a system which has already, in the hands of speculative builders, worked so much woful mischief to the national taste.

BOOKS RECEIVED.

Album of Decorative Figures, by J. MOYR SMITH (London: Sampson Low and Co.), is a varied collection containing subjects to suit all tastes. We like best some of the tile-decoration subjects and some of the more ambitious subjects least. The frontispiece—"The Summer of Civilization"—intended to represent Hellas in its prime, seems to us alike unsatisfactory in conception and execution, though the last-named defect may be due to the process by means of which it is reproduced. The few Scriptural subjects in the book do not seem to us at all suitably rendered. The best of the larger illustrations is the double page representing "Terpander Singing in Lesbos," a composition fairly full of life and spirit, and in which the accessories of costume, &c., seem to have been fully studied.—*Practical Geometry for Art Students*, by JOHN CARROLL (London: Burns and Oates), is the second edition of a cheap and simple course of lessons on the construction of plane figures and scales, pattern-drawing, geometrical tracing, and elementary solid geometry, adapted to the second-grade art syllabus of the Science and Art Department.—*The Garden Oracle*, by SHIRLEY HIBBERD (London: *Gardener's Magazine* office), has reached its 24th annual issue.

An inquiry was held at Barton-on-Trent on Thursday week before Mr. Arnold Taylor, an inspector of the Local Government Board, respecting an application from the town council for sanction to borrow £21,600 for market-hall, gas-works and street improvements. The inspector expressed a doubt as to whether the market-hall would be found large enough for the wants of the rapidly-growing town.

Another section of the South London Tramways system, about 1½ miles in length, was opened on Monday. It extends from Chelsea Suspension-bridge, via Victoria-road and Queen's-road, Battersea to Lavender-hill.

OUR LITHOGRAPHIC ILLUSTRATIONS.

GAYTON MANOR HOUSE.

A SMALL view of this house is given in Baker's "History of Northamptonshire," published in 1812, but the only information afforded is, that it was "built in the time of Elizabeth or James," that it stands at the north end of the village, and that it has now become a farmhouse. The walls are built of a beautiful grey stone, common in the locality; and the fact that so many of the windows are bricked up, rather adds to, than detracts from, the beauty of the building, the red and orange of the brickwork forming a most pleasing contrast with the grey of the stone. The building at present appears to have escaped almost entirely from the hands of the modern workman. Right in front of the house stands the village-church, a most interesting structure, containing several fine tombs and some good woodwork. I believe this is now being restored by a clever local architect, who, it is to be hoped, will refrain from doing more than is absolutely necessary for putting the fine old place into an efficient state of repair, many of the churches in the neighbourhood having suffered deplorably from over-restoration.—ED. W. MOUNTFORD.

DESIGN FOR A CERTIFICATE OF MERIT.

THIS design was placed first and adopted in a competition originated by the Committee of the Midland Counties Art Museum, Nottingham Castle, some months ago. The certificate itself is intended to be awarded to successful picture exhibitors at the autumn and other exhibitions held annually at this building. The conditions require that the drawings should be prepared in pen and ink, and that the design should have represented in it the Castle Museum itself. The author of the design is Mr. Arthur Marshall, architect, Cauldon-place, Long-row, Nottingham.

POLESWORTH VILLAGE HOUSE.

ADJOINING the parish-church of Polesworth there were, many years ago, a group of buildings, a portion of which had been used for religious purposes, the other part being in use as a manor-house, the walls of the principal rooms were lined with oak paneling. The site and buildings having been given to the parish, a vicarage-house was built on the site of the old manor, a portion of the ancient walls and all the oak paneling being preserved. The site of the old library or parsonage, which was formerly the refectory, has been preserved, and also the old stone chimney in the room. The manor-house was destroyed a few years ago by the late Mr. G. E. Street, R.A.

HOUSE AT EWHURST.

THIS house is to be built at Ewhurst, in charming country, near Cranleigh, in Surrey. The principal aspects are south and west, with views over Sussex to the sea. The external walls will be built hollow, of local stone of a brownish colour, with brick lining, the roof covered with tiles and chimney-shafts of red brick. Special instructions were given for the battlements and low roofs which have been employed. The internal joinery will be of oak, felled on the estate for the purpose. The billiard-room is over the kitchens and heated by hot water therefrom. The illustration is from a drawing in the last Royal Academy Exhibition.

MURAL TILES FROM GREAT AND LITTLE MALVERN ABBEY CHURCHES.

AMONG the very many valuable remains existing at Great Malvern of Medieval tiles, those illustrated by one of our lithographic pages to-day may be taken as good typical examples. Those shown *in situ* are from the reredos screen on the north side of the high altar. The colours are built on a dark background, softened and toned; the mellow character of which is necessarily lost in a black and white reproduction. The spirit of the drawing is worthy of remark, specially in the heraldic figures of the shields. Fig. C is a large tile from the sacristy of Little Malvern Church. Fig. D is a copy of an old Dutch tile in blue, and the remaining Figs. E and F are from France.—M. B. A.

NEW CATHOLIC CHURCH AND CONVENT, DUMFRIES.

THIS building, now in course of erection, is being built for the nuns of the Perpetual Adoration, at the cost of the dowager Lady Herries. It is situated on the top of Corbelly-Hill, Maxwell Town, Dumfries. The site is a most beautiful one, being the highest point in the neighbourhood, and commands a view of the country for many miles. It is built with the local stone, the dressings being polished and the facings rock-faced. The colour of the stone harmonises well with the surrounding scenery. The whole of the church, but only a portion of the convent, is now being built. It has been designed and is being carried out under the superintendence of Messrs. Pugin and Pugin, of Westminster. The contractor is Mr. John Dowlin, of Glasgow; Mr. Ely is the clerk of works. The illustration we give was in the Royal Academy, but in colour.

IN our sheet, published last week, of sepulchral monuments, by Messrs. Brindley and Weatherley, our lithographer omitted the title of the well-known incised slab of "lairs" stone, which we illustrated from Châlons sur Marne, France. Its date is about 1338. The other two examples shown were from Italy.

COMPETITIONS.

WEST KENINGTON CONGREGATIONAL CHURCH.—Messrs. J. Cubitt and J. M. Brydon's design has been selected in limited competition. A thousand sittings are provided in a nave with unusually wide bays and with little obstruction to sight. There are a central tower and shallow transepts. Schools, class-rooms, and a lecture-hall are also provided for on the site.

A new Primitive Methodist chapel was opened on Christmas Day in Station-street, Newport, Mon. It is built of hewn local stone, with Bath stone dressings and measures 63ft. by 57ft. A gallery surrounds three sides of the building; the roof is octagonal and open, and is constructed of pitch-pine; the seats and rostrum are of the same wood. The chapel is seated for 520 persons, and beneath it is a school-room for 120 children. Messrs. Habershon and Fawcner, of Newport, are the architects; and Mr. John Linton, of the same town, is the builder. The cost has been about £5,000.

The railway-station at York, the largest provincial station in England, is being repainted and decorated; the ironwork in two shades of Woolston's Torbay blue, and the woodwork in white, with vermilion line round the panels. The contract has been taken by Messrs. Adams, Robertson, and Sons, of Alwick and Newcastle-on-Tyne, and Mr. Frank Plenty has inspected the work under the superintendence of Mr. Coppertwaite, the North-Eastern Railway Company's engineer.

THE CITY CHURCHES.

THE following account of the cost of the fifty churches built in London by Sir Christopher Wren is taken from the *Gentleman's Magazine* of July, 1734:—

	£	s.	d.
St. Paul's	736,752	2	3½
Alhallowes the Great	5,641	9	9

St. Vedast's, Foster lane	1,553	15	6

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

MANCHESTER SOCIETY OF ARCHITECTS.—The annual report of this society, which has been issued, contains an expression of regret on the part of the council that the responses of students in connection with competitions for which valuable prizes were offered, even with an extended allowance of time, were very far from reaching the standard desired. The council, however, are unwilling to come to the conclusion that the small number of students who come forward is in consequence of indifference or want of interest in the profession. They have decided to continue the prizes for the present session, and to leave the choice of subjects in the hands of the students themselves, in the hope that by so doing many may be induced to compete who would not otherwise do so. The council again arranged to give a prize to the students of the Building Trades Institute, and the response was very satisfactory. The council considers that, so far as the students themselves and their work are concerned, the money devoted to prizes by the Institute is well spent, and it has pleasure in recommending that they be continued. Referring to a paper read by the president of the society (Mr. J. Medland Taylor) at a conference of architects in London, in May last, upon the important question of quantities, the committee stated that opinions differed as to whether an architect should himself take out the quantities for his own works, or should delegate that part of the work to an independent surveyor, and until the question was settled the Council considered that each architect should act upon his own judgment as to what is best for the interest of his clients. The Council recommended (and it was now required under the by-laws of the Royal Institute of British Architects) that quantities, if taken out by the architect, should be so done with the full concurrence of the client, to whom the question of quantities should be properly explained, and that the payment of such services should be made direct by the client, and not as heretofore through the builders.

Mr. A. Holt has been elected first borough surveyor of Lewes, at a salary of £200 a year.

[illegible]

FUNERAL OF MR. G. E. STREET, R.A.

IN the presence of a vast congregation, the remains of the late highly-gifted leader of his profession were yesterday (Thursday) afternoon interred in the nave of Westminster Abbey. The cortege started from Mr. Street's residence, 14, Cavendish-place, Cavendish-square, about 2 o'clock, and proceeded via Regent-street, Waterloo-place, Cocks-pur-street, Whitehall, and Parliament-street, to the Abbey, which was reached just as Big Ben was striking three. The procession consisted first of the body, in a plain unpolished oak cased coffin, covered by a purple pall with scarlet cross, and resting upon a funeral car; seven mourning coaches, containing the relatives and private friends, the chief mourners being Mr. Street's only son, Mr. Arthur Edmund Street, M.A., A.R.I.B.A., and his brother and sister; and the office staff. After these followed the members of council of the Royal Academy in four carriages, and after these nine carriages, in which were the following past-presidents, vice-presidents, and members of council of the Royal Institute of British Architects:—1st, Professor T. L. Donaldson, past-president, now the sole survivor of the founders of the Institute; Messrs. John Whichcord, past-president; Charles Barry, past-president; and Geo. Godwin, F.R.S., past vice-president. 2nd carriage: Messrs. Horace Jones, V.P.; Ewan Christian, V.P.; F. C. Penrose, M.A., P.V.P.; David Mocatta, P.V.P. 3rd carriage: Messrs. A. W. Blomfield, M.A.; James Brooks, David Brandon, Arthur Cates. 4th carriage: Messrs. Joseph Clarke, John Gibson, H. Curry, and O. Hansard. 5th carriage: Messrs. J. T. Knowles, Alfred Waterhouse, A.R.A.; E. G. Paley, Lancaster; Thos. Worthington, Manchester. 6th carriage: Right Hon. W. H. Smith, M.P.; Col. Sir Andrew Clarke, R.E., C.B., K.C.M.G.; and the secretaries of Institute. 7th carriage: Sir P. Cunliffe Owen, C.B.; Mr. P. C. Hardwick, M. Emile Trélat, Paris (representing the hon. and corresponding members of Institute); Mr. J. Abernethy, Past President of Institution of Civil Engineers. 8th carriage: Messrs. J. G. Symons, F.R.S., President of the Meteorological Society; C. L. Eastlake, Keeper of the National Gallery, and ex-Secretary of Institute; Joseph Goddard, President of Leicestershire Society of Architects; and J. P. Seddon. 9th carriage: Messrs. T. M. Rickman, J. Tiltman, President of Northern Architectural Association; and J. W. Connor, President of Leeds Architectural Association. To these succeeded a carriage containing the President and Secretaries of the Architectural Association, Messrs. Aston Webb, Eales, and Berry. Following these were the private carriage of the Prince of Wales and many private carriages. The procession entered the Abbey by the west cloister door, and proceeded through the nave and choir to the lantern, beneath which the body rested on tressels, while the first portion of the service was read by Canon Duckworth. The pall-bearers were the Right Hon. A. J. B. Beresford-Hope, M.P., past President of the Institute, and also representing the Royal Architectural Museum; Sir Frederick Leighton, P.R.A.; the Right Hon. G. Shaw Lefevre, M.P., First Commissioner of Works; Mr. W. H. Gladstone, M.P., representing his father, who was a personal friend of the deceased; Mr. Edmund Freshfield, representing the Society of Antiquaries; Professor T. Hayter Lewis, F.S.A., senior vice-President of the Institute; the Bishop of Winchester, Dr. Harold Browne; and the Hon. Justice Kay, representing her Majesty's judges. The long procession completely filled the space under the central tower and the transepts, and overflowed into the sacrum, which was already densely occupied. It would be manifestly impossible to find space for the names of many of those present, but the number included the following members of the Academy, in addition to those already mentioned of the Council:—Messrs. Alma Tadema, E. Armistead, Vicat Cole, Hodgson; and members and Associates, Messrs. J. E. Millais, C. Herbert, P. Calderon, W. Oulss, R. Horsley, E. Long, W. Calder Marshall, H. S. Marks, T. McQuoid Whirter, T. O. Barlow, W. Q. Orchardson, G. Aitchison, Marcus Stone, E. J. Boehm, Birch, and Eaton, secretary; and among architects, other than those already named, may be noted Professors Kerr and Roger Smith, Messrs. J. Fergusson, F.R.S., E. P. Anson, W. White, E. R. Robson, W. Woodthorpe, R. W. Edis, R. Phené Spiers,

teacher of drawing at the Academy; H. Jarvis, J. D. Matthews, B. A. Paice, H. H. Stannus, T. E. Colcott, Bloomsbury; G. D. Oliver, Carlisle; W. Wood Bethel, Westminster; H. G. W. Drinkwater, Oxford; the latter four former assistants; Tanner, Gaudy, and S. Vacher, from Mr. Street's office; Wallis, clerk of works at the Law Courts; H. G. Margitson, principal stone-carver at same; W. T. Creed, a former clerk of works; Mr. Thomas Hawkesley, past-president, and members of the Institution of Civil Engineers, and many clergymen, builders and contractors. At the conclusion of the first portion of the burial service, and the singing by the choir of the anthem, "How Blessed are the Departed," the procession reformed and followed the body to the place of sepulture. This is on the north side of the nave, close to the new pulpit, and beside those of Robert Stephenson, Sir Charles Barry, and Sir Gilbert Scott. While standing around the open grave it was impossible to avoid recalling the last funeral at this spot, in April, 1879, when Mr. Street, with evident emotion, acted as one of the pallbearers to his great predecessor, whose chairs at the Academy and Institute he has subsequently filled, and whose memorial brass he designed. Here Dean Bradley read the latter portion of the service, and the anthem, "His body is buried in peace," having been sung, the friends pressed forward to take a last look at the coffin, which was nearly hidden by the wreaths of flowers thrown in, while the great organ pealed forth the "Dead March" in *Saul*.

THE LATE MR. ANTHONY SALVIN.

THE following additional particulars of the career of the late Mr. Anthony Salvin have been sent to us for publication:—

The late Anthony Salvin was the son of General Anthony Salvin, of Sunderland Bridge, in the county of Durham, and the representative of that branch of the ancient family of the Salvins of Croxdale. He was born October 17th, 1799, was educated at the Durham School, and lived many of his early days with his uncle, the Rev. Wm. Nesfield, at Brancepeth Rectory. The restoration of Brancepeth Castle was then going on, and the youth, much interested in the operations, doubtless at that time acquired the taste for architecture which determined his choice of the profession he followed during the remainder of his long and active life. He came to reside in London about 1820, and with his future brother-in-law, William Nesfield, the painter, mixed in the society of the art-world of that time, Turner, Prout, and others, and was for a short time in the office of Nash, when the elder Pugin was in the office. He joined the Society of Antiquaries in 1824, and lived to be the oldest member. Salvin began practice at an early age, as in 1828 he built Mamhead, near Exeter, for Sir Robert Newman, at a cost of about £20,000; and in the same year Morby Hall, for Mr. Henry Preston, at a cost of £40,000; and in 1829 had the gratification of being called in by Mr. Russell to restore the Great Hall at Brancepeth Castle, the building which inspired his career.

Then followed in quick succession such works as Methley Hall in 1830, for the Earl of Mexborough; Parham, for the Honourable Robert Curzon; and many others of equal importance. Mr. Salvin was consulted for many years on all matters relating to Government castles, and his skill and knowledge of Mediaeval fortresses well warranted the confidence reposed in him. His careful studies of the remains of English and Welsh castles in all their details is shown by his sketches, which are admirable both for their artistic merit and archaeological knowledge. Amongst the most successful of his works may be named Peckforton Castle, which was built from the foundation for Lord Tolemache, also the restoration of the Beauchamp Tower and Traitors' Gate at the Tower of London. The careful manner in which Caernarvon Castle has been kept from ruin may be credited to Salvin's influence in high quarters, and his enthusiasm for our ancient work.

At Wind-or Castle he was somewhat controlled by the late Prince Consort, as in the restoration of the Curfew Tower, but in all things he earnestly endeavoured to be Conservative. Alnwick Castle was restored by Salvin for Algernon, Duke of Northumberland, between the years 1852 and 1861. This was his great work, and the outlay was princely. The

decoration of the interior was controlled by the Duke, who insisted on its being carried out in the Italian Cinque-cento style, and for this purpose Cardinal Autonelli, at the Duke's behest, persuaded Commendatore Canina to come from Rome with a number of Italian artists and carvers; but the whole of the internal work was under Salvin's direction.

Keele Hall, in Staffordshire, near Newcastle-under-Lyme, built for Mr. Ralph Sneyd, between 1855 and 1862, is probably one of the best planned houses in England, from its clever adaptation to the ground. In planning Salvin was an adept. The court-yard is on a low level, and, a flight of stone steps, similar to the ancient arrangement of Parham Court, approaches the great hall on the first floor, on which the principal apartments are arranged, the basement being occupied by servants' offices. The whole is most artistic and a model of attention to old work. Amongst his later works Thoresby Hall, in Notts, commenced in 1864 for Earl Manvers, and finished in 1875, is conspicuous; and the restoration of Dunster Castle, for Mr. G. T. Luttrell; Petworth House, for Lord Leonfield; Longford Castle, for Earl Radnor; Encombe Hall, for Earl Eldon; and Birdsall House, for Lord Middleton, are all works of first-rate importance. Salvin may be said to have died in harness, a wholesome and good thing for a man of 82 years.

As late as last year he was building a house in Chesterfield-gardens for Lord Leonfield, when the growing infirmity of age compelled him to relinquish the task. But his work did not end here, for within the last few months, and greatly at his own expense, he interested himself in the restoration and enlargement of the church in the village of Fernhurst, Sussex, near which he lived during the last 17 years of his life. His anxiety at the last was that the bells which he had bestowed should be hung in the new tower and toll his departure. He died on Dec. 17th, 1881.

Salvin was a true gentleman that the profession may be proud of. A man of business and courteous, as all who knew him, employers and employed, will acknowledge.

W. E. N.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual dinner of this Association took place on the 22nd inst., Mr. John McLachlan, architect, president, in the chair.

After the usual loyal and complimentary toasts, Mr. John Honeyman, president of the Glasgow Institute of Architects, proposed the toast of "Success to the Edinburgh Architectural Association" in the following terms:—

Mr. President and Gentlemen,—I feel highly honoured by being called upon to propose the next toast, "Success to the Edinburgh Architectural Association." You have much reason to be gratified with the result of your past labours, especially in recent years, and much reason, too, to be encouraged by such success to attempt something more. I feel that I cannot refrain from alluding to that sad event which has come upon us so suddenly. Knowing Mr. Street as I have done for many years, although too seldom privileged to associate with him, both his words and his works have more and more impressed me with admiration for the greatness of his genius and the true nobility of his mind, and I realise with the added poignancy of personal sorrow, the greatness of the gap which his removal now leaves in the ranks of our profession. Enthusiastic yet practical, devoted to his art and not without ambition, yet unselfish—valiant, yet tenderly sympathetic—he was indeed, as Mr. Christian so well expressed it last Monday evening, "a prince and a leader" among his brethren.

In Mr. Street's address at the opening of the Institute he alluded to the difficult problem of how best to promote a closer union among the many architectural societies scattered over the country. This problem remains for us to solve, not to shelve; and it is on this subject I should like to say a few words before resuming my seat, believing that it has an important bearing on the responsibility of all architectural associations. Surrounded by men whose zeal I admire, whose abilities I respect, and whose esteem I covet, and who have so cordially extended to me the right hand of fellowship, I feel that it would be

difficult to find a more fitting occasion for alluding to this subject, and advocating the wide extension throughout our profession of those elevating sentiments, which, I may say, are at once the motive and the result of its effective unity. If we could only honestly say that we have surmounted those stumbling-blocks of prejudice and misconception which cumber our path, and that we have got the length of treating our brother-architect exactly as we would desire to be treated ourselves, we would clearly see how common aims, common hopes and fears, trials and triumphs, friends and enemies, and—shall we not say?—common devotion to a noble art, should bind us together, and beget within us a jealousy not merely permissible, but beneficent—a jealousy of ourselves and of our brothers lest we bring dishonour on the name we bear.

Now, undoubtedly, proper organisation must greatly contribute to such results; but hitherto we have hardly tried to turn it to the best account. You gentlemen, at least, have proved that you appreciate the advantages of meeting together in an association, the influence of which is, I am sure, not confined to those who are members of it. We in Glasgow have done the same. There are many such associations throughout the country, but I think I am right in saying that there are only these two societies in Scotland; and it is very sad to think that hitherto they have, to all intents and purposes, stood to each other very much in the relation that the Jews did to the Samaritans of old. I am sure that all who are here will agree with me in thinking that this state of matters is hardly creditable to us, and that a more cordial relationship would not only be agreeable and helpful to us as individuals, but that it would strengthen our influence as a profession in Scotland; and, taking a wider range, and considering the relations of all architectural societies to each other, it seems to me that one of our greatest wants at present is some scheme for bringing them all together in closer alliance, and facilitating intercommunion. Far be it from me, however, to advocate anything in the shape of amalgamation. We want federation, but I don't think we want to be called confederates; and both theory and experience point to the advantage of a proper division of labour and responsibility. Some of you may remember that a bold and, for a time, successful attempt was made to gather into one society everyone in Scotland—east and west, north and south—who was interested in architecture. It is exactly thirty years since I was admitted a member of the Architectural Institute of Scotland. I felt much interested in its work, and had little doubt about its success. Its professed object was exactly the same as yours—exactly the same as that of the present Glasgow Institute. This, indeed, is expressed in the laws of the old Institute and in ours exactly in the same words—"The advancement of the art and science of architecture." The Institute did good work for a few years, and then it gradually began to show signs of weakness; there were twists and ugly separations, indicating something wrong with the foundations, and at last it suddenly collapsed. This collapse had one bad result: it caused alienation between the architects of Edinburgh and Glasgow, and I think I may safely say that they have never been such good friends since, but on other grounds the split was not to be regretted, and it would certainly be entirely wrong to say that it was caused by the petty jealousies and animosities of the professional members. The causes of the Institute's dissolution were inherent in its constitution. Being a national institution, it was right that its headquarters should be here; and it was natural, though not right, that a majority of its council should belong to Edinburgh. The Glasgow section was thus controlled by the Edinburgh section, and as the former comprises a majority of the Fellows, and of the other members, the situation soon became irksome, and of long standing. Now, doubtless, if the Institute had confined its efforts to the promotion of the union of the profession in Scotland, with the elevation of the qualification and status of its professors, or to the enlightenment of public opinion on matters architectural through the agency of its mixed membership, more skilful management might have averted its fate, but, when, as themselves a considerable in the last stage of such pursuits are but a small portion of the work of any architectural

society worthy of the name. Your own experience, gentlemen, as members of this Association, must bear me out in this—that an architectural society must have much work to do of merely local interest—work educational, deliberative, or, it may be, actively defensive or offensive (not using the word offensively), the importance of which men at a distance cannot realise, and in the conduct of which their interference would be impertinent. And so we should not be surprised to find—indeed, it is exactly what might have been expected—that it was differences of opinion about enterprises of local utility which brought matters to a crisis, and led to the disruption of the Institute. Its history has, I think, a lesson for us now, and I therefore trust you will not blame me for saying so much about it.

That lesson seems to be this—that provincial societies are most likely to be useful in their respective spheres—to be vigorous, influential, and long-lived—if they are responsible for the management of their own affairs, and entirely free from any extraneous interference.

I have not the least fear that such independence will lead to selfish isolation and indifference to matters affecting the profession as a whole; on the contrary, independence, if it does not beget benevolence, and all charitable emotions, acts well as their foster-mother; and without doubt it is the parent of respect—respect for our fellow-workers, respect for ourselves, and hence a reciprocity of goodwill and esteem, the solid and only permanent basis of that union which is strength.

But, gentlemen, if we desire our profession to obtain what I may call national recognition, and to stand out among others in its true position and dignity; if we wish, as a profession, to give authoritative expression to our opinions, to encourage the highest culture, and to provide the most excellent facilities for education and research, to maintain friendly relations with our brethren in other countries, to be intrusted by the Legislature with certain useful functions; and by our Sovereign with the distribution of honours, the gracious bestowal of which testifies to her continued interest in our art—I say, if we desire as a profession to perform such duties and to enjoy such privileges, you must be perfectly sensible that it is impossible for us to do so through the agency of independent isolated local associations; and hence on the one hand the fitness and the need of one great national association, and on the other the duty which rests upon every architect to give it a loyal and hearty support. The want of this too generally, the want of it I may say specially, in the good city of Edinburgh is the only reason why the Royal Institute of British Architects is not a still greater power in the country than it is. Its influence during the past years (now nearly 50 since its establishment) has been great and beneficial, and it gives every promise of increased usefulness.

If I have not already exhausted your patience, I should like to add that there is one reason or excuse for keeping aloof from the Institute which has always seemed to me to be most inequent and foolish—namely, an objection to certain of its by-laws and regulations. Now it is surely evident that if a large section of the profession object to anything of the kind, and yet admit the utility of the Institute, their duty is to join it, and take some pains by their advice and by their votes to bring about improvements and promote efficiency. Of this I am very sure, gentlemen, that as you go on perfecting your organisation here, and doing diligently the important work which you alone can profitably undertake, your thoughts will often wander beyond the verge of your own field of labour, and the conviction will grow upon you that, with all your energy and all your influence, there is still beyond the scope of your endeavours valuable work to be done for the profession which the Institute alone can accomplish; and if this conviction induces you to join its ranks—as I hope, and indeed believe, it will—you may rest assured of this, that the effect of this more formal alliance with brethren in every part of the country will be felt by you to be at once an incentive and an aid, strengthening your position and expanding your sympathies, and thus, in the most direct and marked manner, contributing to that lasting success of the Edinburgh Architectural Association which we all here so sincerely desire, and to which I now call upon you to pledge a flowing bumper.

PRACTICAL NOTES ON PLUMBING.—XXIII.*

By P. J. DAVIES, H.M.A.S.P., &c.

(Continued from page 823.)

INSIDE WORK, OR SANITARY PLUMBING—TWIN CLOSETS—FIXING AND WIRING CLOSETS.

A REFERENCE to Fig. 126, chapter XX., of this article will show the necessary traps and pipes to be fixed to twin closets, and Fig. 136 illustrates the two closets as fixed. Both

these closets are supplied with water through service boxes and submerged valves, from the cistern above. When such valves are used they

are generally actuated by means of a strong copper wire, CW, 1/4 in. in diameter, and by the use of the cranks BA; also the ball lever D,

* All rights reserved.

which answers, as its name implies, as a lever, to change the direction of the wire, and as a weight to bring up the wire. When fixing these closets it must not be overlooked that it is essential in all cases, without exception, to fix them over a proper lead safe, M, fitted with a good overflow pipe.

Though to some experienced hands in the trade it may appear superfluous, it is necessary to remind the younger ones that it is very requisite to use great care when bedding down, or as it is better known in the trade, when setting the closet, so that, when screwing it to the floor, the bottoms of the lugs and lead-work are well painted before the putty is applied; also that the closet must be properly bedded on good putty before the screws are put in. In the upper part of this diagram is shown a Bramah closet fixed over a U-trap, and there is also shown the old method of fixing the overflow of the safe into the side or cheek of the trap. There are plumbers even to this day who adopt this style, and I think that they are in this point decidedly in error.

Fig. 137 is a diagram of a pan-closet as fixed over a U-trap. This kind of closet I have long since condemned, but as there are thousands of plumbers who think otherwise, and will insist on fixing the old pan-closet, I deem it almost a matter of duty to apprentices in the trade to describe the proper method of fixing them. Some of my readers will probably more easily recognise this diagram under the title of "wired closet," which means that the valve in the cistern is actuated by the use of a wire C W (closet-wire). The cistern should be lined with 6lb., or, better still, 7lb. lead, and the valves fixed over a service-box properly wired.

WIRING AND CRANKING CLOSETS.

The best method of doing this is to fix the cranks so that they may pull in a line one with each other. Use side cranks, M A, Fig. 138, for changing horizontal directions, as also at B, Fig. 137, and upright cranks W X, Fig. 138, for

changing the pull-line from a horizontal to a perpendicular, as shown at A, Fig. 136.

Fig. 139 shows the method of fixing cranks to a pan-closet without the use of a side crank, and which gives underhanded motion. P is

where the power is applied from the lever of the container, and W the end working the weight. It will very readily be seen that if you pull up the first crank at A, that this power will be communicated to that corresponding point of the second crank C, and affect whatever is at the end of the wire W. Now suppose you cannot go in a straight line with the wire W, but have a wall to pass through, as at E, Fig. 140, you must, under these circumstances, connect the wire W, Fig. 139, to N, Fig. 140. In this case the crank is shown to work back or with crossed wires, which allows the wire N to work close up against the wall E. Here notice the difference with the crank H. M G, as it is now fixed, throws the wire F at least 6in. away from the wall, and is a clear indication that the person who fixed it did not know his business.

The proper way to fix the foot of this crank is lower down at about S, so that the wire may pull from above the rivet line or about T, which would throw the crank to work backwards as K J I, and thus allow the wire to come near the wall.

By turning Fig. 140 upside down, and joining F on to P, Fig. 139, the whole of the work may be reversed. That is, pull at N, and you actuate

W, Fig. 139, and by turning Fig. 139 upside down, you at once get an overhead motion, or in other words, pull the wire, and you actuate W. The above is the method of fixing cranks to the bottom of joists or ceilings, and will answer

in situations where ball levers cannot be employed. Of course, in instances as here described, a weight must be fixed on the wire W to draw the wire back, or a check-spring may be employed.

In the selection of cranks it is always necessary to see that they are not put together with an iron rivet; they must be brass and work loosely.

If by any chance they have become clogged up and stiff through the use of oil, place them over a moderate fire and so burn out the oil; but remember that if you put them over too hot a fire you will most probably melt the rivet.

HINTS ON HOME SANITATION.*

By H. H. COLLINS, F.R.I.B.A., F.I.S. (Hon. Sec. of the Health Department, Social Science Association).

ALTHOUGH we cannot always select, yet we can all discriminate, with regard to the amenities and surroundings of the locality of the house we intend occupying. Given a certain number of residences from which to determine, we may choose that one which, from various reasons, is the one most free from objections, and which possesses the fewest defects. For example, we may endeavour to avoid a too-crowded locality—one surrounded by narrow and ill-ventilated streets, alleys, or lanes, the devitalised air of which would be sure, sooner or later, to prejudice the one we are about taking. We may give the preference to a detached or semi-detached house well bathed in air, to that of a terraced house, cribbed, cabined, and confined. We may choose between two sides of a street, so as to obtain the best aspect, say a south or south-westerly one in lieu of the other points of the compass. We may select a gravel, loamy, or well-drained subsoil in lieu of a damp, ill-drained clay one, and we may carefully refrain from dwelling in a house the foundations of which rest on fetid debris or former dust receptacles. We can easily ascertain if illness has been prevalent in the locality. We can see if roads are made, and with what materials, and we can easily ascertain if the same have been "taken to" by the parish, sewered, lighted, and supervised by competent responsible authority. Before entering into the occupation of any house we may protect ourselves against the incalculable evils arising from bad drainage, or roofs not watertight, by obtaining a verbal or written assurance that the same are perfect and the house consequently fit for habitation. It would be advisable to secure such a guarantee in writing, or such assurance given in the presence of witnesses. Quoting from the judgment of Mr. Baron Pollock, it will be seen that if such assurance is given, ignorance or carelessness upon the part of the landlord will not excuse him. "If persons take upon themselves to make assertions as to which they are ignorant, whether true or untrue, they must, in a civil point of

view, be held as responsible as if they had asserted that which they knew to be untrue." Mr. Justice Kay, in another judgment, said, "Now, what is enough in law to make a man liable for an action for deceit? It is enough that either he knew the statement he made was not accurate, or he made it recklessly, without having knowledge about it one way or the other." Lastly, with respect to exterior considerations, we should give the preference to that house which has the thickest walls, the greatest amount of light, and appears to be the most substantially constructed, carefully avoiding being led away by a showy exterior, however picturesque, or overlaid with (too often) meretricious ornament, for most of these so-called advantages are the means of retaining dampness, garnering filth and dirt, and preventing the escape and evaporation of the natural humidity of our climate. The dust-bin should not escape our notice; we should take care that it is so positioned as not to prove a nuisance; properly ventilated and moved as much away as possible from any of the ingresses to the house; nothing but dust and ashes should be allowed to be placed in it—vegetable and matter liable to decay should be burnt each day. The first consideration with regard to the interior of the house is its sanitary condition. Assuming that its external drainage is guaranteed and perfect, we must carefully see that there does not exist any connection with the main sewerage and the house proper. This is not difficult. See that the waste pipes from the sinks are open at their ends and pass outside; also that the overflow-pipes from cisterns are similarly treated. A simple plan for keeping waste and overflow-pipes clean is to obtain a cane and bind round its end a piece of rag or sponge, wet the same, and pass it up the pipe once or twice. See that sinks are placed against external walls and under window openings. Ascertain the position of w.c.'s; if situated in the centre of the house, give the preference to that house where the conveniences are positioned against an external wall, and lighted and ventilated from the outside; recollect that w.c.'s off staircase landings are the best. Take care that the w.c.'s are supplied from a separate cistern, so that no communication exists between the drinking-water cistern and themselves; this can easily and economically be effected by interposing a small waste-preventing cistern if it be necessary. See that the soil-pipes are of lead, and carried up their full bore above the roof, away from all windows or other ingresses to the house. It is an ordinary practice to make common light east-iron rain-water pipes serve both for soil and rain-water; this should not be permitted, but if the landlord objects to substitute lead for iron, then take care that the joints of the iron pipe are thoroughly air and watertight, and that the pipe is carried up above the gutter as just mentioned, and a branch put in to take the rain-water. In any such arrangement it is essential that the soil-pipe be exterior to the house. If possible it is very desirable that an open trap, Potts' Edinburgh or Buchan's, should be inserted at the feet of these soil-pipes. Pan-closets should be avoided; simple earthenware hopper closets are much preferable and more economical in first cost. If safes or trays are placed under w.c.'s, take care that the overflows therefrom pass direct into the open air. Let me recommend you to always close down the flap of the w.c. every night, shut the door and slightly open the window, and once or twice a week to have the basins washed out with dilute spirits of salt. There exists no reason why the basins of the w.c.'s should not be as clean and the water as pellucid as that of a drinking-fountain. Ascertain the position of the eisterns; these should be accessible, so that they may be cleaned out frequently, as if placed in roofs, under stairs, or jammed into sculleries, they soon become neglected and sources of disease; all eisterns should be covered. All drinking-water should be boiled and filtered, and if charcoal be employed as the filtering medium the same should be renewed at frequent intervals. Several filters worthy of attention are to be found in the exhibition, notably the Carferal and Maignen's "Filtre Rapide." If the bath forms, as it should do, a portion of the fixtures, take care that its overflow and waste-pipe discharge into the open air, and I should advise that means be taken to carefully shut off draughts by placing indiarubber seatings between the wood and metal work (the same

* Paper read at the Brighton Health Congress, December, 1881.

observations apply to w.c.'s). Similar remarks apply to all fixed lavatories, slop-sinks, &c., which should always be placed next external walls, and not in the centre of houses, where they are most productive of prejudicial effects. Let your preference be for that house which has an amplitude of light, is free from dark and unventilated passages; cupboards, closed dressers, nooks and corners are not always the conveniences they appear to be; they form, as a rule, receptacles for all the neglected dirt of a house to congregate in, and are fruitful sources of danger; every housewife will recognise that by exposing to the full light of day the pots, pans, and household requisites, she will be better able to preserve them clean, and what is equally necessary, whole, unbroken, and fit for use. Never use as a bed-chamber an apartment without a fireplace, for here it is that "the death of each day's life" occurs when vitality requires all the assistance which can be afforded to it. Ventilation is of vital importance to the hygiene of house and occupant. Guard yourself against the inconvenience and annoyance of smoky chimneys by special agreement with your landlord, but a smoky chimney is even better than having none at all. A simple and cheap means of obtaining ventilation without draughts is the insertion of a board about 3in. wide between the bottom rail of the sash and the sill of the window; but if you can obtain from your landlord fireplaces having hollow chambers formed round same, so that in winter air may be admitted in a warmed condition, and in summer in a cooled state, so much the better; many such are to be seen in your exhibition. I have hitherto spoken of the admission of pure air, but it is equally, if not more, necessary to extract, or at least to allow egress of, the foul air. This can be readily obtained by means of Sheringham's ventilators, Arnott's valves, and contrivances of a like nature being inserted in the outer walls, or in special flues, or in the chimney breasts, and at very little cost. It is very desirable that all halls and staircases during winter should be warmed; a good gas-stove will, if there be no other way, be a simple means of procuring this; but never adopt gas as a heating medium without the stove or apparatus is furnished with a flue to permit of the escape of the impure air: nothing can be more dangerous to health than the neglect of this hint. Attention should also be given to the state of the gas service: it should be examined and tested with a taper to see if there be any escape. As regards the appropriation of rooms, of course this depends on the class of house; but as a matter of common-sense, and consequently of sanitation, there is no difficulty in any class of house to select proper aspects for each apartment, bearing in mind the purpose for which they are to be devoted, thus: the dining-room, as probably the least used room in the house, may have a northerly aspect; the sitting and drawing-rooms, southerly and westerly; the kitchens, westerly; the larders, &c., northerly; nurseries, the same as sitting-rooms, and so forth; so that the largest amount of health and enjoyment may be extracted from even an ill-planned and ill-arranged dwelling. A "hint" as to paper-hangings will not be amiss: take care that they are not arsenical in colour and composition. One "hint" more with regard to the house and its belongings, worth all the rest: do not imagine that when structure, drainage, water supply, and the various appliances appertaining thereto, are left in perfect condition, that they will always remain so, and that, unlike every other production, they will last unimpaired for ever, or even that period of "for ever," a few years. If you desire health, you must work for and deserve it; constant supervision to insure great and continual cleanliness is essential. You cannot "nag" your domestics too much on this score; you cannot be too watchful, whether the house be large or small, whether it belongs to peer or peasant, if you wish to preserve it as a pure wholesome dwelling in which to live, instead of to die in. This is a duty you owe to society quite as much as to yourself, bearing in mind that public sanitation is mainly, if not entirely, dependent on private hygiene, and that the law declares in unalterable accents, "Secutur non tuum alienum non lodes." "That people must make use of their own property in such a manner as not to injure that of others." But there are other hints equally necessary to glance at—such, for example, as food. I am

afraid, as a rule, it is exceptional for the lady of the household to pay that attention to the kitchen department as was the honoured custom of the last century. In aristocratic families the duty devolves on the housekeeper, who delegates it to her assistant, who hands it on to some underling. In middle-class life, the cook, whether she be skilled or unskilled, reigns supreme. In the less elevated classes, an utter ignorance seems to prevail of dietary necessities. Goldsmith tells us that "Heaven sends us good meat, but the devil sends cooks"; and if this latter gentleman have an existence, I am sure a large proportion of my audience will be of the same opinion. How can "good digestion wait on appetite, and health on both," when the elements of the chemistry of food and cooking are absolutely unknown to the housewife? The hint here is to practically make yourselves acquainted with "what to eat, drink, and avoid." How much thrift may be engendered; how much household saving effected; how much good-humour secured; and how much health preserved by a little knowledge and some care given to this subject! First, as in all chemical operations, absolute cleanliness is required in pots, kettles, and utensils. Due weight—this will not suit the butcher! Purity of concomitants—a wail from the grocer! Economy in their use—warning from the cook! The meat weighed and washed; the vegetables cleansed, salted, and soaked; the fish carefully examined and well cleansed; the cloths free from impurities; the knives, spoons, &c., &c., clean and fit for use. Lastly, the result, a delicious meal, effected at half cost, productive of comfort and replete with health-giving properties. Sanitation is so wide a subject, and embraces so much that is essential for the welfare and comfort of mankind that "hints" might be multiplied "ad infinitum"; but I cannot conclude without calling your attention to one other matter of every day but yet of equal importance with the other subjects to which I have directed your attention, namely, "clothing." Dr. Max von Pettenkofer, Professor of Hygiene at the University of Munich, writes: "One of man's principal defensive weapons in his struggle for existence is his clothing; the place it takes in the history of civilisation and its connection with physiology are not often thought of; it is spoken of from a moral and æsthetic point of view; its main purpose is a purely hygienic one." He adds that "the forgetfulness of this is to be deemed a great misfortune, inasmuch as small and frivolous considerations have subjected mankind to many ills, and have often acquired an ascendancy over better and fitter hygienic clothing." The seeds of grave disorders and chronic illness are frequently—very frequently—promulgated by the neglect of well known principles with regard to clothing. This is a large subject, and I would refer you to Pettenkofer's work, wherein you will find much instructive and interesting matter; but I would mention that he calls attention to the fact that we generally consider clothing as an apparatus for keeping air from us, whilst in truth we could not bear any garments which did not allow of a continual ventilation of our surface. It is therefore necessary that we should make ourselves acquainted with those textures which being most permeable, afford us the warmest clothing. It is not the densest, thickest, or heaviest material which is best suited for our purpose. My "hint" on this head is that, as our health is so intimately associated with the economy of our dress, you should begin to think for yourselves with regard to it; emancipate yourselves from the tyrannical dominion of fashion, and study to obtain a deeper insight into those laws of clothing which will inevitably tend to increase the longevity of the community and to enhance its comfort and enjoyment. There are, as I have said, a host of other subjects connected with domestic sanitation, such as those relating to furniture, &c. On this head I would "hint" at the desirability of taking care that it should be of such form and character as to prevent the lodgment of dirt and dust; all hollows should be filled in, and all unnecessary ornamental projections dispensed with; under any and all circumstances a continual application of elbow-grease is very advisable. Too much caution cannot be exercised with regard to various matters external to the house, but often productive of serious consequences internally, such as the selection of the laundress, char-woman, scum-tree, tailor, &c. It is a "hint"

worth attention if the lady of the house would visit, or at least ascertain the character and surroundings of, the homes and workshops belonging to these people before availing herself of their services; good in countless ways would result from such knowledge. As my pen writes these concluding observations, I seem to hear a murmur that I have quite lost sight of the remark with which I commenced this paper, and the question inevitably arises, "That since life can little more supply than just to look around us and to die," is it worth the trouble of practically adopting the many hints laid down for our guidance? Cui bono? Has ever a people so lived, and if so, with what results? My answer is, Yes, and with the happiest and best of results; results which were intended for all, and which all may attain. Without entering into any polemical disquisition as to whether the laws to which I am about to refer were of Divine origin or not, or whether they have been acted upon by religious or superstitious motives; that they were wise and beneficent, if we judge only by results, there can exist no doubt. The Laws embraced every matter upon which I have lightly dwelt—household, dietary, personal, sumptuary, and every conceivable sanitary question affecting the happiness and life of mankind. Explained and amplified by the sayings of the Jewish race, they have acted as their guiding star for over 5,000 years, and have preserved them in health under unexampled difficulties up to the present day. Dr. Richardson thus writes:—"Facts show that from some cause or causes this race presents an endurance against disease that does not belong to other portions of the civilised communities. The resistance to those influences which tend to shorten the natural cycle of life is singularly instructive." He gives statistics which show that amongst infants 10 per cent. die amongst Jews, and amongst other denominations 14 per cent. That the average duration of the life of the Jew is 48, of others only 36. That a quarter of the Jews live beyond 71 years, and of others 59 years and 10 months. That the extracts from the civil state papers of Prussia show a mortality of the Jew 1.61 per cent., as against the mortality of the whole kingdom of 2.62. That the annual increase of the Jews is as 1.73 to 1.36 amongst other denominations. He adds the Jews escape great epidemics more readily than other races. The mortality of cholera, for instance, was so slight that the fact of its existence was even disputed. He attributes the main causes to what he calls "sobriety of life," thus interpreted by him—sobriety, better food, carefulness in the rearing of children, thoughtfulness for their aged and infirm, general care of their poor and also of themselves. Whilst in no way disputing the conclusions which Dr. Richardson has arrived at, I venture to assert that most of these beneficial effects have been the results of continuous and unremitting attention to the sanitary and hygienic laws laid down by Moses and amplified by his disciples—Laws which, for the first time in the history of the world, proclaimed that "Prevention was better than cure"; that the real science of medicine lay in the direction of prophylactic rather than therapeutic measures. That by the laws he laid down—not as a monopoly for Jews alone, but open to all who desired to live by them, admittedly onerous but undeniably efficient—he not only prevented disease, but if, unhappily, it arose, he took all those measures which modern science has revived to stamp it out.

NOTES FROM EDINBURGH.

THE lack of enterprise which characterised most departments of industry at the commencement of the year has continued to the close. The course of unseasonable weather, which set in after the month of June, adding another to the list of bad harvests, has given the depression of the agricultural industry an absorbing interest: and till matters look more hopeful in that quarter, the return of busier times for the builder will be unlikely to occur. Wages continue at the lowest point: masons getting 6d. to 6½d. per hour, and others in proportion. A fair amount of work has been sanctioned by the Dean of Guild Court during the year—mostly alterations on existing property; and in the extremities of the city chiefly, instal-

ments of speculative schemes have been carried out. In the farthest north, in Ferry-road, a lot of eight small, "self-contained" houses has been built, which may be noted as presenting an agreeable variety and a much-desired improvement on the sadly stale monotony of the door-and-bow-window style. These are built in the cottage style of the Queen Anne period, but with simple details suitable to the character and prospects of the property. They are small houses specially in request by those who like to have only their own house over their head. The architect's hand is apparent in the detail and proportions, which is more than can be said for the houses which have been erected during the year in furtherance of the scheme for building on the Warrender Estate. No respect has been paid here to the character of neighbouring houses, which are all of a superior class, nor to the character of the street, which is one of the main approaches to the city. The tenements are not out a story too high, but the details and proportions of doors and windows betray the absence of architectural design, where a little thought and a little extra cost can do so much to help what must be the uniformity of a street. The whole has the pauper aspect of a third-rate tenement. In the extreme west, amid green fields and within about a stone-throw of the Water of Leith at Coltbridge, a very lofty range of tenements, with commodious shops, presents a striking contrast to all the neighbouring edifices, which are suburban villas or cottages of very moderate size. Albert-street, in Leith-walk, is now completed; but building in this direction has not been very active, owing probably to the exorbitant feu duties. In view of these additions made of recent years at the outskirts, a Bill is being prepared for extending the municipal boundary.

The electric light was introduced on the 25th August, the evening of the National Volunteer Review. The wet weather, and damp condition of the vault under the new bridge, where the generating apparatus was placed, prevented its working after a few hours' trial. The lamps are about 50 yards apart, and have never given a very strong light, owing to the tension of the wires, which are exposed to the action of the wind overhead. The period of trial (three months) is about to expire, and the Gas Company have been experimenting on the South-bridge, with lamps having Bray's triangular arrangement of lights. The relative cost of the electric light as compared with that of the present and improved method of lighting Princes-street with gas, is thus given in the *Scotsman*, 4,000 hours being the yearly amount of light:—

Ordinary light, £203; best method of gas lighting, £500; and the electric light, at 2d. per hour per lamp, £1,100.

The wood-pavement of Queensferry-street has proved a failure, and has been replaced with the causeway laid in other streets. In rough weather it was always dirtier-looking than the stone, and more so as it began to exhibit irregularities of surface, when it rapidly disintegrated under the heavy and continuous traffic to which it was exposed. The very uniform level of the street may have been against it. No experiment in the way of street-paving, hitherto attempted in the city, has proved, in respect of durability, equal to the Val de Travers road-way, laid about twelve years ago, in the Kirkgate of Leith, a very narrow but very level thoroughfare. It has undergone, in several places, the torture and disturbance inseparable from the system of pipe-laying adopted, but is still, to all appearance, as intact and serviceable as at first. In wet weather the inequalities appear but trifling compared with the hollows which are seen in causewayed streets, even when bedded in cement. Curiously enough, the Val de Travers of the footway in the North Bridge has had to be relaid within the same period, and this time it is done with Limmer asphalt.

In street architecture of more ornamental character there has been little done. The most noticeable is the very extensive frontage built by the publishers, Messrs. Nelson, as a screen for their works in the Dalkeith-road. The design provides a large central entrance, with a range of offices on either side. The whole is executed in the Scottish Baronial style of ornate type, not without some resemblance in details to the Perpendicular or Elizabethan. The range is in one story, but the gateway has two floors and lofty pyramidal roof, flanked with corner

turrets, and finished with parapet and ornamental details peculiar to the style. It was designed by the architect, Mr. Lessels, to harmonise with the mansion-house, built for the proprietor in the adjoining park. This edifice, as well as Salisbury-green, beside it, is a good sample of the Florid Baronial, and strikes the eye by its picturesque appearance and happy adaptation to its site, having the "crown of the causeway" to itself.

Two rather ambitious-looking alterations in George-street make prominent objects, of some novelty in their design. The one in what may be considered Greek Classic, with porticoes at either end, and window-spaces carefully studied in their proportions for the several floors. The other is Italian; but in this case the frontage is too narrow and too lofty for the character of the detail, which cuts up the whole surface into meaningless strips, with piers, pillars, and pilasters. The doorway is in the style affected by some of the Queen Anne architecture. It has a low lintelled door and an absurd-looking little square hole for transom-light, where all the light that can be got is wanted.

The masonry of the north front of the University extension is now complete, and the roofing timbers are being placed on it. Internally it is in the confusion of a state of progress when many trades are busy. The same may be said of the work of restoration in St. Giles. The work here was begun immediately after the term, as the congregation were provided by Dr. Chambers with accommodation elsewhere till their new church was ready. Galleries and old plaster were speedily removed, and for a while a glimpse of the fine proportions of the vaulted nave could be had; but at present the interior is a forest of scaffolding, the heavy work of removing Mr. Burns' pillars and substituting new ones being now in hand.

The Tower of Free St. George's is nearly complete, and its outline easily seen through the scaffolding. It is of good altitude, 180ft. more or less, and will be a notable landmark in the city, in excellent contrast to its neighbours, the dome of old St. George's, the Perpendicular tower of St. John's, and the massive spire of St. Mary's Cathedral. The church itself is Classic Italian, of ponderous details, massive pillars, pediments and cornices. The new addition has nothing in accord with it, and may be described as a very plain tower, with open belfry stage and lantern above it in the emasculated and eclectic Classic of Queen Anne. The little sculpture employed is flat and of the monumental order, heads alternating with honeysuckle, &c. The pilasters at the angles of the tower are finished off at base of the belfry stage as buttresses, with weatherings having a section of double curvature. Over these the base mouldings project slightly, and these in their turn are carried back with large cavetto sweep to the piers of the belfry stage, which stand considerably back from the lines which form the tower, giving a quaint bell-cast outline to this portion of the edifice. The belfry-stage is Greek, i.e., it has on each face three lintelled openings, the angle piers being carried up above the upper details, to a moderate height, when they have pyramidal tops. The lantern stage is still lighter in design, and is octagonal or circular, with eight circular-headed openings, and conical roof boarded for lead or slate. The outlines for distant effect are all happily proportioned, and the only questionable arrangement is the treatment of the pilasters, which seems to intensify the change from the heavy to the lighter style, the belfry looking more discontinuous in its aspect than if the pilaster projection had been diminished, the apparent bulk of the tower reduced, and the ordinary treatment employed. The merit of the design lies in its simplicity.

Church-building has been, as hitherto, considerably greater as the building trade has been decreasing. Five or six churches have been opened in the course of the year, and as many more are in progress. They are mostly built for the accommodation of outlying districts of later growth, with exception of the church at Dumbiedykes, which is in an old quarter of the town, but one very densely populated. This edifice has been fortunate in finding funds for the completion of its spire, which, although a modest erection, has a fine effect of much greater altitude, arising from its being built on a site midway in one of the steepest streets of the city. It is a galleried church, and with Early

Gothic detail and aspidal end. The Free Church, of Granten and Wardle, in the north outskirts of the city, follows the modern arrangement of the Gothic nave, with narrow passage aisles and transepts. It has a completed tower, and was erected at a cost of about £5,000. It is an anti-galleried design. The U. Presbyterian body have erected a large church in Eyre-place, occupying a splendid site forming the centre, of which a large crescent is the circumference. This church is also ante-galleried—i.e., it has only an end gallery, and by far the greater proportion of the audience are in the area, which is a plain rectangle of rather ungainly width. The congregation are admirably placed as regards the pulpit; but in order to give something like a tolerable appearance to the walls, they are pierced with so many and such large windows on all sides, that the interior is more like a conservatory than a church, and the largest or gable windows face the congregation. The front exhibits the usual arrangement, the gable being reduced in breadth by tower (not finished), and staircase at the other side, "all vertical lines," suggesting something very different from what meets the eye around the corner. The cost of erection was £7,000. The most noticeable sample of an attempt to improve upon the old galleried system, is a very large church built by the U. Presbyterians for the Merchiston district. This was opened lately, and no expense apparently has been spared to make it what it is, one of the most commodious and comfortable churches in the city, in which all the members are placed in the best position as respects the pulpit. The cost was about £13,000. The proportions of the church as to width are much greater than those of the edifice previously mentioned—not less than 45ft. within the piers of the nave. The task of making this interior something better than a railway-shed, even with plenty of funds at command, was not an easy one. But it has been fairly accomplished, and with good proportion as to height, it carries its waggon-boarded ceiling well, the base resting on hammer-beams, or struts of Norman character, which have groined pendentive attachments to the walls. The plan is rectangular, the piers of the nave being massive, of square and quatrefoil section. The arches are low compared with height of clerestory wall, and would have had more pleasing aspect if the ornamentation had been more varied, with more of Norman moulding and less of the Norman billet. The aisles are used only as passages. A vestibule stretching across the front gives access to the interior. This has groined vaulting, very well designed, but its convenience is purchased dearly at the expense of light for the greater portion of the church beneath the gallery. The pulpit is a rostrum, with organ-loft over a lofty wall-screen behind. This serves effectually to dispose of the blank wall-space, but the detail is too flat, and the choir arrangement has too much of the look of a secular orchestra. The building is not so happy in its exterior, which is, perhaps designedly, somewhat of a medley. The Norman chevron adorns the principal openings. The principal doorway in the north gable is profusely decorated, and has a rather shallow interlacing arcade over it, with three lofty lights above. The ordinary method of masking the true proportions as to width has been resorted to, and had it not been for the buttressing, and especially that employed to convert what should have been a Norman bell-turret into a Gothic tower, this north elevation would be a very good specimen of the old Norman front. The tower, however, is a strange mixture of Early Gothic and Perpendicular in the management of its details, till it gets up to where the belfry-stage becomes Norman, with a pyramidal roof of stone. The belfry openings are very short, and look shorter, owing to the absurd length of the opening immediately below. The clerestory is very high over the aisle, and has an uncompleted look, as it is topped with a heavy row of corbels, which carry nothing but a thin line of iron gutter. The windows are lofty gable triplets, in the unbroken surface of the wall, and of purely modern Italian design. The church looks best from the eastern side, where the proportions as to length are better; and the tower appears as a bell-turret over the gable.

The fifth church was opened lately at Dalroy. It is a galleried church. The site was inconveniently small, and no attempt has been made to combine it with the hall built beside it, or

improve upon the popular Nonconformist Gothic of thirty years ago. A large number had to be accommodated in the least possible cubic space; and gallery beams are carried across the pointed windows at the side. The small clock-turret is built at the angle of the front, which carries a spirelet of very ambitious altitude. The cost was about £5,000.

THE HEALTH OF NAVVIES.

IN view of extensive canalisation soon to be done in France, the Minister of Commerce lately consulted the Academy as to measures that should be taken to preserve the health of workmen engaged. A report by M. Colin is the result. In it he notes the persistence of a depressed vital state in certain parts of the country, especially the coast departments, which are chiefly concerned in the works projected. Marshes by their mix-ma are not the sole cause of this "impaludism" (as he calls it); but virgin soil, newly turned, emits morbid germs, whence arise intermittent fevers, &c. With regard to precautionary measures, the report specifies the following:—1. Fragmentation of work, not attacking too many points at once, not entering on a piece of work before the piece next to it, begun previously, is finished. 2. Choosing strong, vigorous navvies, by preference inhabitants of the region; and 3, diminishing the time of contact with the soil. The work should be stopped at times when it is known to be dangerous—viz, July, August, and September, and in the extreme morning and evening hours. Evening vapour on plains and low lying parts is very dangerous. Large fires should be lit in the works morning and evening. 4. Lodging of the navvies in neighbouring centres of habitation, as much as possible in the heart of towns and villages, and on high ground, or where near the sea in pontoons moored at some little distance from the shore. Fevers do much less injury among workmen who reach their homes at night, than among those who remain on the works. 5. A special diet: before his work the navvy should have a substantial hot meal; preventive medications (such as arsenic, extract of nux-vomica, and sulphate of quinine) have not yielded such results as recommend their use. 6. Immediate conveyance to the hospital of a navvy attacked by fever, and caution as to premature re-engagement of men discharged from hospital. 7. Early filling of the excavations, admitting water, in urgent cases, to parts which prove peculiarly infectious, and stimulating vegetation on ground newly upturned.

CHIPS.

We omitted to state last week that the solid parquet floors in the two drawing-rooms, dining-room, library, breakfast-room, boudoir, billiard-room, hall, ante-hall, &c., at Rousdon, the new seat of Sir Henry W. Peck, were laid to special designs by Messrs. A. J. Arrowsmith and Co., of 83, New Bond-street.

At a meeting of the restoration committee of Church Down, near Cheltenham, held on Wednesday week, Mr. H. Philpott, of Cheltenham, was appointed architect, and it was decided that the second section of the work to be carried out in 1882 shall consist of the re-roofing of the nave, south aisle, and parvise-chamber over porch, and the repairing of stonework on tower and battlements. The chancel was restored last year.

A temperance café was opened at Bourn, Lincolnshire, on Wednesday week. Mr. Wilcox, jun., was the architect, and Mr. Topham, of Bourn, was the contractor.

Amongst the new Common Councillors for the City of London elected on Thursday last week was Mr. Alexander Peebles, F.R.I.B.A. Mr. H. H. Bridgman, A.R.I.B.A., was defeated at the poll.

A serious landslide occurred last week at Andoversford, in the deepest cutting on the Cheltenham and Banbury Railway. About 10,000 tons of saturated clay were displaced, and a gang of 100 men will be occupied for a fortnight in restoring the line.

At the meeting of the Chelsea board of guardians last week, it was proposed that Mr. Harcastle be appointed quantity surveyor for the workhouse extension; but, after a discussion, it was resolved to invite several surveyors to tender for the work.

Holton St. Mary Church, Suffolk, was reopened on Friday after restoration.

Building Intelligence.

BURSLER.—On Tuesday afternoon the new building erected at Burslem for the guardians of the Burslem and Wolstanton Union, as a board-room and offices, were opened. The building has been erected from the designs of Mr. G. B. Ford, architect, of Burslem, by Mr. J. Bowden, at a cost of £1,818, in addition to the purchase of the site, costing £112. The style is Queen Anne, and the building is constructed almost entirely of red bricks, with moulded strings. The ground-floor contains board-room, 27ft. 6in. by 10ft. 9in. and a relieving-office, collector's-office, waiting-room, &c.; and the upper story has offices for the clerk, registrar, overseers, &c.

CHURCH EXTENSION.—The usual monthly meeting of the Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels was held last week. Grants of money were made in aid of building the new churches of St. Barnabas, Caneway Lake, in the parish of St. James', Wolverhampton, £250; and St. Chad's, West Cosely, Sedgley, Stafford, £350; enlarging or otherwise improving the accommodation of the following churches—viz., Greatworth, St. Peter, near Banbury, £20; Halstead, St. Andrew, Essex, £60; and Walkern, St. Mary, near Stevenage, £10. Under urgent circumstances, the grant formerly made towards re-seating and restoring the church at St. Pinneck, near Liskeard, Cornwall, was increased from £25 to £10. Grants were also made from the Special Mission Buildings Fund towards building the mission churches of St. Clement's, in the parish of St. Andrew's, Fulham, Middlesex, £20; and Acton-green, in the parish of South Acton, Middlesex, £30.

DARLINGTON.—The usual Christmas decorations at St. Cuthbert's Church, Darlington, are this year supplemented by a piece of decorative work of a permanent character. The ancient panelling at the back of the chancel-stalls, which was destroyed in 1748, has, through the liberality of the Duke of Cleveland, lay rector of the church, been restored from the drawings of Mr. J. P. Pritchett, who about 15 years since carried out the main restoration of the chancel. As every particle of the old panelling was destroyed, the restoration has been imitated from that now existing in the chancel of Staindrop Church, where the stalls, and especially the ends, are so exactly like those at St. Cuthbert's, that they must have been executed from the same drawings, if not by the same hands. This is the more interesting, as at that time one of the Neville family, who owned Raby and Staindrop, was Bishop of Durham, and changed the constitution of Darlington Church from a vicarage to a deanery. By Mr. O. borne, contractor, of Darlington, the work has been executed out of beautiful old English oak, which, after being in the roof of Middleham Church for 300 years, was taken down and replaced lately by a modern roof of foreign oak, during a so-called "restoration" of the church. The carving is an excellent reproduction of the old work at Staindrop. Two of the stalls—the place of honour—viz., the "return" stalls on north and south sides facing east, are enriched by having the coats of arms, crests, mitre, and coronet respectively of the Lord Bishop of the Diocese and the Duke of Cleveland blazoned in colour by Mr. Low Heral, printer, of Darlington. A further improvement in the chancel is the removal of the coils of hot-water pipes, which for about fourteen years had disfigured the chancel. This has been done by the churchwardens.

OUNLEE.—The structure being erected at Oundle, for the Grocers' Company, for the grammar-school, is now drawing towards completion. The buildings are in the Tudor style. The principal front stands back about 9ft. from the street line, and is about 130ft. in length, and 30ft. high to the top of the parapet, with an octagonal bell-turret at the corner about 48ft. in height, and a tower 20ft. square in the centre, on the top of which is the flag-turret, reaching to a height of about 60ft. The external facings are of finely-axed stone from the Sutton pits; the dressings to windows, arched, &c., are of Ketton stone; and the strings, plinths, copings, &c., are of Clipsham stone. The whole

of the internal finishings to windows, doors, &c., are of wainscot-oak, and all the floors to classrooms, corridors, and masters' rooms, are of the same material, with plastered walls and ceilings, and cement dados. The roofs are covered with green slates, with ornamental red tile ridges. The whole of the works are being very satisfactorily carried out by Mr. John Thompson, mayor of Peterborough (who has been ably represented constantly on the works by Mr. Wm. Bradford), and from the designs, and under the personal superintendence, of Mr. J. Sebastian Gwilt, architect to the Grocers' Company, London, aided by Messrs. Shoppee, his surveyors.

"To a practical man with a taste for mechanics, and the hums of constructive fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion;—*The Brightonian*. Price Two-pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph Advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—B. on T. U.—W. B.—T. L. B.—T. L.—W. A.—V. of K.—P. G.—S. and P. L. B.—V. T.—W. F.

F. Write the Secretary, at 12, Great George-street, S.W.

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—Sigma, H. F. S., Eclipse, Rollo, Just my Luck, Othello, That's my Idea, Beta, K., Spes, Eos, Fred, Good Luck to Your Fishing, Confido, Ambition, Semper Paratus, Gramgram, Bean Stalk, Try, "Crescam" in crescent. One of Them, June, Deva, H. A. G., S. W. R., H. S. L., L. S.

THE LATE MR. GEO. CHILDS.

Is addition to the sums acknowledged last week, we have also received the following:—

Mr. Thomas Archer 3 3 0
Mr. C. J. Fergusson 1 1 0
We have forwarded the amounts sent to us to Mrs. Childs, and are requested by her to tender her grateful acknowledgments to those who have assisted her.

Correspondence.

PROVINCIAL ARCHITECTS AND THE INSTITUTE.

To the Editor of the BUILDING NEWS.

SIR,—As Mr. Thomas Drew appears to be so very anxious for argument, I have again perused his letters which appeared in the BUILDING

News of December 2nd, 9th, and 23rd inst., and divesting them of eloquent padding, and feeling conscious of my inability to grasp their transcendently practical conclusions, I am only able to thus summarise them.

"Not to seek unduly for the increase of the numbers of Fellows of the Institute."

Required "a United Kingdom list of registered members of the Institute," and into this to "sweep every provincial architect of decent repute, competency, and irreproachable professional conduct, admitted by the recommendation of trusted Fellows of the Institute, by ballot or examination," or as Mr. Drew afterwards proposes, "Every fairly competent and qualified practising architect in the three kingdoms held in his locality of practice in honest and honourable repute."

The "annual subscription maintaining such registration to be one guinea, or even a more moderate fee." Now what is there in Mr. Drew's suggestions worth the consideration of Institute? The present constitution must not unduly seek its increase; but when the register is open it may "sweep" (as Mr. Drew euphemistically terms it) every decent architect into it. And, so far as I am able to read, just about on the same conditions as Associates, and Fellows are now admitted. Mr. Drew knows that after the 31st inst., an applicant will not be put up for admission, unless he undergoes an examination, and, judging from his description of the examination for admission to the dentists' association, the R.I.B.A., will not fall short in that respect. What, then, becomes of the grand movement of Mr. Thomas Drew? Where are his suggestions of practical value? Where are his "definite propositions" which are now in force at the Institute?

It appears to me that the important alteration which Mr. Drew desires is that funny little notion about election by, I presume, local brethren—very pretty in conception it no doubt is—but would it be an improvement on the present system? Perhaps, though, from the point of view of a local architect, it would be thoroughly satisfactory. One can well imagine half a dozen local practitioners assembling some evening at the local "pub" or meeting-house, and, after exchanges of mutual admiration, they decide that they are all "honest and of honourable repute"; they each and all determine to place themselves on the "register" at the price desired by Mr. Drew, viz., half a guinea (certainly not exceeding one guinea); they elect each other, and half a dozen names are added to the list of provincial architects. Surely this is sufficiently "encouraging," and would, no doubt, "sweep" every provincial architect into the Institute; but whether or not the dignity of the body would be thereby increased, must be left for Mr. Drew to determine.—I am, &c.,

WM. WOODWARD.

SIR,—As there has been much discussion lately as to the value of the letters "R.I.B.A.," any facts relating thereto will be of interest. A short time ago a work in London was intrusted to me, and I found (which is not surprising) that my name had not been the only "Richard in the field." I also learned that one of the arguments used in favour of my employment was that I did not happen to belong to the Institute. Those concerned, of course, had their own reasons for avoiding members of that body; these, however, did not include a desire to also avoid the payment of the usual five per cent. (The full commission was paid with high compliments thrown in.) I can hardly think that my experience stands quite alone; it, however, certainly goes to corroborate the too-patent fact that, with the mass of the public, membership of the Institute at present counts for little. Even in London some of the most gifted, as well as most distinguished architects, have never belonged to it. But with proper management, a future generation may see a different state of things, and to this end I think that suggestions for judicious reforms, especially from our brethren in the country, should be respectfully received, and carefully weighed by those who are responsible, at least to some extent, for the future status of the Institute.—I am, &c.,

A LONDON ARCHITECT.

CLERKS OF WORKS.

SIR,—It is good news to hear that "Another Clerk of Works's" experience is that the appoint-

ments of ratepayers' associations are only the exceptions to the rule, though the advertisement columns of the BUILDING NEWS scarcely bear out the assertion, and my experience of these associations is that the reputation of the architect, or the efficient carrying out of his views, are entirely subservient to the gaining of a victory in a paltry petty squabble among the doubtfully favoured few who hold honorary office under the vacillating sufferance of an electorate.

But I cannot agree that my position is altered, because a clerk of works and jobbing carpenter may take an office that a builder's foreman might decline. Possibly a poor struggling architect, did his pride permit, would often be glad of the regular earnings of a clerk of works, or even of this jobbing carpenter.

In the neighbourhood from which I write, there is a notable instance of an architect in practice entering the lists in the manner I have indicated, as a quasi clerk of works, and carrying out board-schools in the very teeth of the Board's architect, who, moreover, is a well-known school builder, and a prominent F.R.I.B.A. I think these anomalies of grade all tend to prove the clerk of works is of the profession, and not in the trade, where trade-unionism drags (or lifts, if you prefer the word) all its members to one uniform level, and most zealously guards against any such infringements. Neither does it signify that a man may be at one and the same time a bricklayer's labourer by trade, and a tin-whistler by profession.

Then as to the mutual advantages of association. A Landseer may, to his professional profit, ally himself with a Frank Buckland, or a keeper at the Zoo, or even with a "dawg"-fancier; but who would think of starting a society for their mutual benefit? So may a young doctor chum in with the chemist, or his pupil, or assistant, and circumstances may even force them to exchange situations, but through all, one is a profession and the other a trade. And although the individuals may continue the best of friends, the duties are inimical. The Custom House officer may get useful hints from the merchant's clerk, and so may the policeman from a thief; but society will never allow them to combine in associations for their mutual advantage. No, let us as a class stand by our employers, who are or should be the architects, and keep professionally aloof from the foremen, who are one with the contractors. The "builder himself" should be the last man on the face of the earth to make the selection to recruit the ranks of the clerks of works. We and the architects should take sufficient leaves out of the book of trade-unionism to arrogate to ourselves the choice of recruits, and there may come a day when a board would no more think of dictating to an architect who his clerk of works shall be, than they would, who shall be his perspective draughtsman.—I am, &c.,

ONE C. W. MORE.

SIR,—Continuing the subject relative to the establishment of a society composed of clerks of works and builders' foremen, allow me to say that it is most urgently needed. It is useless for your correspondent to say otherwise, or to try to instil into the minds of others that they should be separate; he is separate, no doubt, if he takes his stand as before even the architect, and I very much wonder indeed that he should condescend to notice my communication from his elevated point of view. As to the remarks made, that distance from his architect favours the builder to become dishonest, and that the chances are largely that he will, I do not assent to that at all; it is not to the builder's interest in the long-run to act so; usually he has to maintain the building some time after it is finished, and scamping work would then tell against him. Nothing whatever is said as to the unjust manner in which some clerks of works will act towards the contractors under them, which, in some cases that I have known, was tyrannical to a degree.

But we cannot establish a society by bickering amongst ourselves; rather should we hold together, those who are in the mind to go forward, having a bond of unity amongst us, and striving to pull together, with a determination to do and accomplish the purpose in view.

The position in which we at present stand, and as depicted by another of your correspondents in this week's issue of your paper, is, to

say the least, deplorable. That we should be obliged to go begging for work in the manner described is not at all satisfactory to my mind. Now, a society established, and in working order, one of its objects should be to take account of those members who may happen to be without employment and further their interests by placing them in work as early as possible. I am sorry for anyone who may be struggling to keep his head up and happens to be without an engagement. It may be urged, we shall degenerate into trade-unionism; but such is not in my thoughts. What I seek is the social well-being of my fellow leaders-on in the trade, and my best efforts shall be brought to bear for that purpose.

Should a meeting in London be arranged, I would endeavour then to propound a course of examinations that I think might very profitably be held. In the mean time, I hope others will come forward and give their views.—I am, &c.,

CHARLES SHORE.

7, Salisbury-terrace, West Fields, Newbury.
Dec. 27.

FULHAM INFIRMARY COMPETITION.

SIR,—We have little time—and less inclination—to answer the criticisms of unsuccessful competitors, except when they state what is not true. This is the case with a Mr. M'Lachlan who tells your readers that in our plan patients must go into the cold air to reach the w.c. and bath-rooms. The most cursory examination of the plan ought to have shown him that the balconies are not open, but glazed.

On the question of estimate it may be useful to this gentleman to know that ours is no guess-work, but the result of experience in recent tendering for similar works; and our views of cost were endorsed by the arbitrator, himself a man of great experience. The difference of 50 per cent. alluded to no doubt represents the difference likely to arise between one who *knows* and one who *guesses*.—We are, &c.,

JOHN GILES AND GOUGH.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.

SIR,—As assessors should, like Caesar's wife, be above suspicion, would not that desirable condition be more assured if others than Mr. Barry and Mr. Carrick were appointed to adjudicate on the final competition? It is to be presumed that in the preliminary selections a strict incognita will have been preserved; that Mr. Barry was unable to identify designs submitted by his London brethren, and that Mr. Carrick was equally ignorant of the identity of Scotch designs. If, however, the same assessors are to adjudicate on the same designs in a matured form, it is evident that the authorship of each one will be known to them.

Assessors, or even city architects, are only human, and as, under such circumstances, a predilection of some one or other of the selected competitors may possibly be suspected to have some weight in the final selection, it would be only considerate to relieve these gentlemen from a position which might leave their action open to misconception.

In the Manchester Town-hall competition, for which preliminary sketches were first submitted and a selection from them made, the same assessor was not employed in the final competition.—I am, &c.,

"TORUS."

P.S.—If the services of Mr. Barry and Mr. Carrick are to be retained throughout, I think the adoption of your correspondent "A. B. C.'s" suggestion, that in the preliminary competition the order of merit of the designs selected should be declared, would afford some assurance to competitors, for then, any departure from this order should account for itself.

KNIGHTLEY v. LETT.

SIR,—With reference to this case I beg to call attention to an inaccuracy in your report. In your last issue you say that "The plaintiff did not attend the trial, and the defendant, after asking for and failing to obtain an explanation from the plaintiff, wrote to the Metropolitan Board of Works." No explanation was refused. The facts are as follows:—Lett sent a messenger asking me to take up the business for him, as he had commenced an action of ejectment against Miss Hambridge, which I declined; he then wrote

me that a letter was written and would be sent by a time he named to the Metropolitan Board of Works, exposing me unless I consented to do what he had asked me. To that I replied "I decline all private practice in my district," whereupon the letter was sent, subsequently withdrawn, and then returned with additions.

I wish it to be understood that all the parties were strangers to me, and that at no time had I had any business transactions with either.

The conclusion of your report is also not quite accurate: a rule only has been obtained.—I am, &c., T. E. KNIGHTLEY.

VALVE-CLOSETS AND THEIR TRAPS.

SIR,—I entirely disagree with Mr. P. J. Davies in his assertion on p. 822 that:—"Under all valve-closets, a properly-constructed ∞ -trap is the only one at present invented that will prove thoroughly efficacious." For my part, I consider "a properly-constructed" siphon-trap much better. The only case where the ∞ -trap might be better would be where there was no allowance for a ventilating-pipe being put in; and experiment has yet to prove the value of improved siphon-traps relatively to the ∞ -traps under such exceptional circumstances.

The siphon-trap Mr. Davies shows at Fig. 129 under his valve-closet is undoubtedly a badly-shaped one for the purpose; but he might have shown a well-shaped one—viz., one with its out-go more perpendicular, as it is often made, and with a deeper water-lock.

I here show one designed and used under a Bramah valve-closet by myself, which I believe won't momentum out, and neither will it siphon out if properly ventilated, and especially if applied under valve-closets led into a 4in. soil-pipe. The section at tongue at bottom may be ∞ .

In practice, where baths, basins, and sinks are frequently branched into the same soil-pipe as the valve-closets, it is often not the trap of the closet itself that gives the trouble, but the traps of the other appliances that empty when the valve-closet is let off; this bad effect being often caused by want of sufficient ventilation, both on the soil-pipe and the branch-pipes.

Of course I don't approve of this plan, and have often to rectify matters where it has been carried out.—I am, &c., W. P. BUCHAN.

21, Renfrew-street, Glasgow, Dec. 26.

THE LATE MAJOR MANT, R.E.

SIR,—Mr. Fotheringham, in your last week's issue, asks permission, *in justice to himself*, to say a few words relative to your report of my communication to the R.I.B.A. on the 5th inst.

Mr. Fotheringham seems only to substantiate what I said, except in one particular—viz., that he joined Major Mant in the middle of 1875, instead of in 1876, as I said.

Perhaps you will allow me also to state, *in justice to myself*, that I read over the whole of my paper to Mr. Fotheringham a week previous to my delivering it at the R.I.B.A.; that I added the paragraph respecting him at his dictation; and further, that on the Thursday following, December 1st, I placed the printed *volume* in his hands to read, the *volume* which you give in full, in which "1876" is printed, and not "1875." That Mr. Fotheringham did not correct it on these occasions is surely his fault—not mine.

I am very glad to hear that Mr. Fotheringham has been instructed by the Baroda and Kolhapur States to complete the working drawings of these palaces. There is none so capable as he is of carrying out these works.—I am, &c., R. PHENIX SMILES.

Carlton Chambers, 12, Regent-street,
London, W., Dec. 25.

ON THE TESTING OF CREASOTE OR DEAD OILS USED FOR "PICKLING" OR PRESERVING TIMBER.

SIR,—The oils used for the purpose of pickling or preserving timber are obtained in the dis-

tillation of coal-tar. That portion of the distillate which has a specific gravity ranging from 1.000 to 1.060 is collected in separate receivers, and after a portion of it has been treated for carbolic acid, the remaining oil is considered as creasote or dead oil. But commercial creasote oil does not consist of this portion of the distillate alone; all the oils obtained in the distillation of coal-tar, after they have been exhausted of their commercial products, if not otherwise saleable, are mixed with the creasote oil. Creasote oil is used in immense quantities by the railway companies for pickling railway "sleepers." Some idea of the extent to which this oil is used may be gathered from the fact that the probable annual produce of creasote oil, in Great Britain, exceeds 30 millions of gallons, and the great bulk of this is used by the railway companies and a few large timber establishments. Contracts for the supply of the oils are let by the railway companies and secured by tar-distillers for periods of from six to twelve months, certain conditions as to the quality of the oils supplied being specified in the contract,—the following conditions, drawn up, or laid down, by Dr. Letheby some 20 years ago, being the most general.

"It should have density between 1.045 and 1.055. It should not deposit any crystalline matter at a temperature of 40° Fahr., it should yield not less than five per cent. of crude carbolic acid to a solution of KHO, caustic potash, of the density 1.070 (14 Twaddell), and it should furnish 90 per cent. of liquid oil when distilled to the temperature of 600° Fahr."

The condition to which I wish especially to draw attention is that relating to the yield of carbolic acid. Many analysts, who have had disputed samples of oils submitted to them, have stated in their reports that the oil contained so many per cents. of tar acids, of which so many per cents. consisted of crude carbolic acid. Now, since there is no known method of estimating or separating crude carbolic acid from other tar acids, when dealing with such small quantities as are obtained in the testing of creasote oils, it would be instructive, and, no doubt, interesting, if some one of these analysts would kindly state the method adopted in determining the quantity of carbolic acid present in the crude tar acids. Again, the question arises, What is meant by crude carbolic acid, since crude carbolic acid is not a definite compound, but contains varying percentages of water, carbolic, and cresylic acids, and other higher homologues? The condition, also, that it shall yield not less than 5 per cent. of crude carbolic acid "to a solution of caustic potash of 1.070" is very indefinite, for it is well known that varying volumes of alkali will extract varying quantities of tar acids; and not only is this so, but the yield of acids depends also on the length of time during which the solution is agitated. Discrepancies may also arise from the fact that the solutions of alkali and oil have densities (especially after agitation) so nearly alike that it is impossible to get a fair result, owing to the imperfect separation of the alkali from the oil. This may, however, be obviated by the addition of petroleum or coal-tar naphtha after agitation.

It is usual, I believe, with many analysts to state the quantity of crude tar acids present as that shown by the increase in volume of the potash solution; but this is not so, since the water always present in creasote oils will, of course, during agitation, be taken up by the caustic potash, and would increase the volume, thus reading as tar acids. Some really remarkable results have been thus obtained by analysts, it being a usual occurrence for them to report that the oils contain 5 per cent., 12 per cent., and 25 per cent. of crude carbolic acid. One eminent analyst some years ago reported a sample of oil as containing 75 per cent. of carbolic acid. The remarkable nature of these results may be understood when we note that the price of creasote oil in bulk is about 2d. per gallon, whilst the price of ordinary crude carbolic acid in bulk, as made in the tar-works, is from 2s. to 3s. per gallon; thus the presence of 10 per cent. of crude carbolic acid would increase the value of the oil at least 11d. per gallon, and with the present high price of tar it is not to be expected that the tar-distiller is so blind to his own interest as to leave a 45 note in every 1,000 gallons of oil he sends from the works, which, figuratively speaking, he would be doing if he left 10 per cent. carbolic acid in the creasote oil.

Again, in regard to the quantity of naphthalene deposited on cooling to 10° F., there is no stipulated time during which this exposure to cold shall continue. Hence another reason for discrepancies.

It has never yet, I believe, been practically demonstrated that the presence of carbolic acid is essential for pickling purposes. The preservative property of creasote oil is probably solely due to the fact that the wood saturated with oil is more impervious to water, and in consequence of the pores on the outer surface being filled with oil, is better able to resist atmospheric influences. In my humble opinion, it would be to the interests of the railway companies to institute a series of experiments on the creasoting or pickling of timber

with oils of varying specific gravities. If the timber was first pickled with ordinary creasote oil, half the usual quantity, and afterwards with a heavier oil containing, in solution, coal-tar pitch, good results would, I believe, be obtained, though the wood would not absorb so large a percentage of oil. This would be compensated for by the greater length of time the oil would remain unvolatilised in the wood. The oils containing pitch on the surface evaporating on exposure would leave the pitch in the pores of the wood, and would thus, as it were, hermetically seal them, preventing the oil in the interior from reaching the surface and evaporating.—I am, &c., CHEMISTIANA.

Entercommunication.

QUESTIONS.

[6383].—**Estimate.**—Will some kind reader of the BUILDING NEWS kindly tell a young architect the mode of estimating the cost of a building at so much the cube foot? Thus I see in the BUILDING NEWS notice of the Fulham Infirmary Competition the following:—"The estimate is £33,750, calculated at 51. per foot." How is the 51. per foot got at? An answer would greatly oblige.—H. F. S.

[6389].—**Floors.**—I am about to design a floor, and have two methods suggested. A sample floor 81 sup. ft. area is taken, 9ft. by 9ft. No. 1 is made with 12in. rough deal boards, ploughed and tongued, resting on 8 joists, 9in. by 3in. thick, with 9in. bearings on walls, 12in. between joists. No. 2 floor is made with rough deals, 9in. by 3in., ploughed and tongued, with 4in. bearing on walls at ends, and in the centre resting on a beam 9in. by 9in., with 9in. bearing on walls. Are these floors of equal strength? What is the cost each? All the timber used is deal.—CARVITO.

[6340].—**Fir and Pine Timber.**—I have read numerous answers and articles in the BUILDING NEWS on the subject of fir and pine timber, and many books on the same subject; but unfortunately am still confused as to the nomenclature. "White deal" appears to be applied indiscriminately to the wood of the trees of two distinct species—viz., to yellow deal (*Pinus sylvestris* or Scotch fir), which has been tapped in the tree of its turpentine and resin, as well as to the wood of the spruce (*Abies excelsa*). Would some of your readers kindly inform me what are the ordinary London market names for each of the following:—(1) "Yellow deal" (or the red wood of the timber merchant, Scotch fir, botanically *Pinus sylvestris*)? (2) The same, tapped in the growing tree of its turps and resin? (3) The wood of the spruce fir, botanically *Abies excelsa*? To this kind of white deal the best Petersburg and Onega white goods are said to belong. *White deal* the South Kensington "Notes on Building Construction," Vol. III. If the 2nd is distinguished in name from the 1st in the market, surely it should also be distinguished from the 3rd, instead of being designated with the 3rd under the common name of white wood or white deal.—L. R.

[6841].—**Reservoirs.**—Will some one kindly inform me which is the best and cheapest way to cover in two reservoirs, 120ft. long, 50ft. wide, and 10ft. deep—one of them "puddled," the other a stone-walled reservoir?—RESERVOIR.

[6842].—**Water Distribution.**—Will some reader inform me of any reliable publication on the distribution of water to towns, &c., also giving details of fittings and general waterworks machinery?—MAXNESSEA.

[6843].—**Building Regulations in Ipswich.**—Can any correspondent inform me whether there are any special restrictions as to height of rooms, drainage, &c., of small houses in the borough of Ipswich; also as to the main points of a sheet of drainage instructions, published by Mr. Buckham, the surveyor of that borough, three or four years since, and favourably reviewed at the time in your columns? I have a small job to carry out in that town, and shall be glad of information.—MAX or KENT.

REPLIES.

[6324].—**Norman Woodwork.**—Mr. A. Nesbitt, in a current number of *Notes and Queries*, refers to the timberwork in the hall of the Bishop's Palace at Hereford as probably dating from the latter part of the 12th century. Can some reader of the BUILDING NEWS give further particulars relative to this ancient oak work?—HARRY HEMS.

[6726].—**Girdler.**—OMISSIONS AND MISPRINTS.—Page 809, second column, 29th line from top, after "From the upper," read "point C" &c.; 4th line from bottom, after "direction," read "to that they had," &c.; third column, 22nd and 24th lines from top, read "40 C" and "C C H" instead of "KGC C" and "C C H K." The letters or signs to the diagrams of the simple trusses to be considered as omitted. In the other diagrams, single lines represent tensile forces or pieces under a tensile strain, double lines represent compressive forces or pieces under a compressive strain, the treble line in the diagram of forces represents both tensile and compressive forces.—HUGO McLACHLAN.

[6760].—**Sp. G. and Crushing Weight of Stones.**—I thank Mr. Hems for his information as to the fact that there is a difference between "Corshill" and "Dumfries" stone. I however guarded myself by saying "probably the same" in reference thereto, being not quite certain of the fact. The fact that I gave in my answer as to the same stone being called by the two names is, I assure him, quite true. This is confirmed by a letter from Mr. Trickett to the BUILDING NEWS, July 30, 1875, when he says, speaking of Red Corshill stone, "sometimes called Northfield Red and sometimes Dumfries Red, with which latter stone it is frequently confounded." Not having seen this letter before, and know-

* Since making this trap I find it is not a brand new modification of Mr. S. S. Hellyer's Anti- ∞ -trap.

ing "Corsehill" stone to come from the county of Dumfries, my mistake was a very natural one. Mr. Harry Hems does not appear to have noticed my exception to the theory of the use of working stones increasing with their strength and hardness. I did not intend to imply that the labour of working Corsehill stone is about three times as great as working Portland, yet I believe it is the case that it is more difficult to work on Corsehill stone than Portland, notwithstanding the fossils and veins in the latter. Now Mr. Hems has again called my attention to the Corsehill stone, I fancy I was wrong in referring to it as having veins "like grain in timber," the stone I was then thinking of comes I believe from York-shire. Should be glad to know where any true Dumfries stone is to be found in London. I am not so much a native of Scotland as some imagine, having been born within three miles of Mr. Hems's birthplace.—HUGH McLACHLAN.

[6778].—**Drain.**—MISPRINT.—For "only" at end of second line read "also."—HUGH McLACHLAN.

[6785].—**Selection by Architect.**—An architect should in all cases avoid ordering goods which he selects, for in the event of client or contractor refusing to pay, or in case of bankruptcy of the latter, he would be liable for payment, though perhaps without chance of recovery. When he selects goods, he should state that they are to be ordered by the contractor and set aside for that purpose, at the same time writing to the contractor to order the goods, giving him a description or number to ensure correctness. If the contractor refuses to order, the architect can withhold certificate. An architect can only select goods according to specification and conditions unless the contractor agrees to his doing so. "Nodmel" should read the case on "Broken Bricks," reported in the "Legal Intelligence" of BUILDING NEWS, Dec. 2.—HUGH McLACHLAN.

[6787].—**Breaking Weight of Girder.**—The formula given by Mr. A. C. Hurley on p. 773 is a good and simple one. He, however, makes one mistake when he says "the safe load for wrought-iron girders is $\frac{1}{4}$ the B. W." This is only the case when the depth of the girder is one-fourteenth of its span or less. In the case given by "Indoctus," the depth being one twenty-fourth of the span, the safe load is $\frac{W}{16}$ or $\frac{B. W.}{16}$; a list of these safe

loads is given in Hurst's "Architectural Surveyor's Handbook." This formula allows for rivet-holes. That by Mr. W. J. Christie is similar to one in Molesworth's Handbook; the result is nearly the same as that given by Mr. Hurley, but it gives a smaller breaking weight. Is not Mr. C.'s allowance for rivet-holes too great? What formula of Molesworth's does Mr. Robinson refer to? Certainly, neither of the two to be found in the handbook.—HUGH McLACHLAN.

[6789].—**Scantling for Tile Roof Rafter.**—Five inches deep by two and a quarter inches broad.—HUGH McLACHLAN.

[6790].—**Clubs.**—The Travellers', Reform, Carlton, United Service, and other clubs in Pall-mall, are all generally considered to be well arranged, but I cannot say where plans are to be found. Plans, &c., of the following have been published:—Manchester Conservative Club House, BUILDING NEWS, Aug. 27, 1875; St. Stephen's Club, Westminster, BUILDING NEWS, Sept. 17, 1875; City Liberal Club, Wallbrook, London, BUILDING NEWS, Jan. 11, 1878; and Conservative Club, Preston, THE ARCHITECT, May 17, 1879. Many others have been illustrated without plans. I have not referred to them.—HUGH McLACHLAN.

[6792].—**Chancel Screen.**—In the Middle Ages Perpendicular screens were often erected in churches of earlier date, though they were then always carried out according to the style in vogue. This argument does not apply in the present day, when the furniture of a church should be in accordance with the style of the church itself, if style is considered. A practical reason for a Perpendicular screen in a modern Early English Church may be given, that it can be carried out in a lighter manner than if it were in accord with the style of the building.—HUGH McLACHLAN.

[6794].—**Problem.**—The answers to this seem to increase the difference of opinion as to the correct solution. One is obliged to say, with W. S. Daws, "all different but all wrong," and might add "some also very confusing." Is not the following the simple and correct answer?

Price paid by A. for lease	£1050
Increased rent last four years	200
	£1250

$\therefore 1250 \div 14 = 89\frac{3}{7}$ nearly, the proportionate amount each year. $\therefore 89\frac{3}{7} \times 4 = £357$ approximately as the amount B. should pay.—T. R. H.

[6797].—**Villa.**—A really good book on house-planning is "The English Gentleman's House," by Prof. Kerr.—HUGH McLACHLAN.

[6805].—**Bath.**—Neither Parian cement nor plaster of Paris will stand the water, as they are not hydraulic cements. I was, however, informed by Messrs. Hoig & Butler, of East Greenwich, who had a stand at the Brighton Exhibition, that there was a process now being brought out whereby cement could be coloured right through the surface. "Alba" had better communicate with them.—LEWES.

[6813].—**Water.**—The water by which "Urgent's" cellars are flooded is evidently subsoil water, the level of which will rise and fall according to the wetness or dryness of the season. The only satisfactory way of dealing with the case will be to drain the site, so as to permanently lower the level of the subsoil water. If that will ultimately be practicable, but is not at present, it is possible to raise the floors temporarily? To attempt to prevent the annoyance with cement, &c., in such a case would fail.—J. S. Manchester.

[6813].—**Water.**—I will guarantee the success of the method proposed by me in a former reply. I have cemented cellars near a river which were flooded in every high tide. Have also built them in gr and full of land-springs, and they are as dry to-day as when made, years ago.—LEWES.

[6813].—**Water.**—In this reply on p. 887, the illustration necessary to render the text comprehensible was omitted and placed by the printer in our article on "Ancient Floors," on p. 816, with which, of course, it had no connection.—E. B. N.

[6816].—**Cracked Sewer Pipes.**—It is the experience of most persons who have constructed and reconstructed pipe sewers of the sizes named by your correspondent "Obliged" at depths of 8 ft. and upwards, that frequently, from unknown causes, the pipes have afterwards been found to be cracked, even when the greatest care has been taken in the selection of the pipes. I have in some cases found the following causes at work. I. Laying pipes on rigid foundations such as rock, compact clay, and hard gravel, without cutting holes for the sockets. II. Lying on yielding foundations as upon sand or made ground. III. By laying them at too great a depth, and not taking sufficient care to insure the consolidation of the earth as it is filled in upon them, so that as soon as the cutting gets thoroughly saturated with water a sudden settlement takes place, and the pipes are instantly injured. IV. As well as by laying them at too shallow a depth. When it becomes necessary to insure the safety of the pipes by covering them with sin or 12 in. of concrete, it is advisable to consider whether brickwork should not be substituted.—J. S. Manchester.

[6817].—**Damp Wall.**—There are several solutions that render brick walls waterproof without concealing the bricks. Some, such as the petrifying process, are patented, others are simple applications, viz., soft soap and alum, size and boiled oil, &c., and appear to be effective when properly done. Brickwork must be set fairly dry, and holes stopped with putty. In very exposed situations several applications are necessary. It is better to make provision in building south west walls than depend on any solution; nevertheless, I have found solutions very useful in several cases.—T. R. H.

[6831].—**Damp Wall.**—If "J. D." will try three or four coats of transparent duresco, made by the Silicate Paint Co., 46, Cannon-street, I think it will have the desired effect, without altering the colour of his brickwork, except to a slight extent.—LEWES.

[6832].—**Soil Pipe.**—I should say that a galvanised iron soil pipe is superior to one not galvanised, provided the spelter used is pure and properly applied; because even if the zinc becomes corroded by sewage vapour, &c., it would be the work of time, whereas unprotected iron exposed to moisture and the free access of air is liable to rapid decay from rust. I am supposing that the soil pipe will be tolerably well ventilated, for zinc in an atmosphere polluted by sulphuretted hydrogen or vitiated by dilute acids, is soon destroyed, no matter whether it stands alone or forms a coating to another metal. The galvanic action between the metals will be to the loss of the zinc and to the benefit of the iron, inasmuch as it will tend to protect the latter from oxidation. The durability of a galvanised iron soil pipe seems to me to depend first upon its quality, the absence of minute cracks and pinholes, and an unbroken and uninterrupted hold between the iron and zinc; and, secondly, upon its occasional external painting and thorough internal cleansing and ventilation.—W. J. Christie.

[6834].—**Damp Walls.**—Possibly no wet comes in, and the indications of damp are caused by a humid atmosphere, especially after a sudden rise in atmospheric temperature, acting on new walls. Possibly the walls are disintegrated or pored, in which case the animal matter of the size and the vegetable matter of the paste having affinity for moisture, cause alarming patches, which, however, are only superficial. A little time for the walls to season, and this action will gradually cease.—T. R. H.

[6836].—**Damp Walls.**—If your cementing has been properly executed you should have no damp. There are probably some small cracks through which the rain penetrates. The wet, no doubt, goes right through brickwork of chimneys. If you do not care to cement them, try three or four coats of transparent duresco.—LEWES.

LEGAL INTELLIGENCE.

COVENANT TO REPAIR.—THE GOLDSMITH'S COMPANY AND THEIR TENANTS.—An inquiry as to alleged dilapidations in certain property of the Goldsmiths' Company was brought to a close on Thursday, Dec. 22nd, before Mr. T. Chaffield Clarke, F.R.I.B.A., to whom it had been referred by Mr. Justice Field. The inquiry arose out of an action for ejectment, in the Court of Queen's Bench, in which the question arose whether the defendant had properly performed his covenants to repair, or whether he had by his neglect sufficiently to carry out the repairs needed by the plaintiffs, rendered himself liable to ejectment under the terms of his lease; and there was the further question whether the repairs which the plaintiffs required the defendant to execute were such as came properly within the covenants he had entered into. The plaintiffs were the four trustees of the Cotton estate, Mile End, Middlesex, and the defendant was Joseph James Grinyer, the tenant of the premises, 146, Turner's-row, on the estate. The statement of claim by plaintiffs set forth that the lease under which the defendant had possession of the premises contained repairing covenants which defendant had failed to observe; that he had allowed the house to get into a state of dilapidation, and that in consequence of this neglect on defendant's part the plaintiff served him with notice to repair on March 15th, 1880, together with a schedule of dilapidations, and that notwithstanding that, the defendant had failed to repair up to the present moment. This action was accordingly brought to recover possession of the premises. The defence was that, although the premises were somewhat out of repair before, they were not so at the time of the commencement of this action, that every-

thing had been done by defendant that he was bound to do by the requirements of his lease, and that he had spent a considerable sum in carrying out such repairs as were actually necessary, that he could not reasonably or legally be called upon to do more, and that, therefore, the plaintiffs had no power to eject him. Mr. Chaffield Clarke was directed by Mr. Justice Field to inquire and report as to the fulfilment of the covenants to repair, the cost of the repairs specified in the plaintiff's notice to repair, whether those repairs were such as the defendant was liable to do under the covenant of the lease; whether at the time of the commencement of the action the premises were in repair in accordance with the notice, and what was the cost of the repairs which had actually been done by the defendant. Evidence was given on behalf of plaintiffs as to the dilapidated state of the premises, and as to the repairs mentioned in the schedule to the notice served upon the defendant being such as he was bound by the terms of his lease to carry out. The witnesses called to support plaintiffs' case were Mr. T. Holmes, John-street, Adelphi, surveyor; Mr. C. Dunch, Clemeut's-lane, architect and surveyor; Mr. J. W. Penfold, Great George-street, Westminster, surveyor to the Goldsmiths' Company, and Mr. H. Beadel, of Messrs. Beadel and Sons, Gresham-street, surveyors and land-agents. Rebutting testimony was given on defendant's behalf, to the effect that all the necessary repairs which defendant was legally called upon to perform had been carried out, and that at the date of the action there was no such neglect as would entitle the plaintiffs to exercise the powers of re-entry given by the lease in case of non-performance of the covenants. The witnesses called on defendant's part were Mr. H. T. Freshwater, Maldon, formerly of the Adelphi, architect and surveyor; and Mr. R. A. Edwards, Devonshire-chambers, Bishopsgate-street, architect and surveyor. The defendant himself also examined and cross-examined at considerable length, and a number of tradesmen were called upon to depose to the work they had done on the premises. The arbitrator having heard the addresses by counsel on both sides, intimated that he should take time to consider his decision.

IN RE WILLIAM ALLPORT.—(Before Mr. Registrar Pepps.)—The debtor, described as of Queen Anne's-gate, Westminster, architect and surveyor, had filed a petition for liquidation; and Mr. Bigham applied for registration of the resolutions passed by the creditors. The debts were stated in the accounts at £1,134, and assets £291. It was resolved that the estate should be liquidated by arrangement, and Mr. T. S. Evans, accountant, was appointed trustee. After some opposition by Mr. McIntyre on behalf of creditors, the registrar on Tuesday ordered the resolutions to be registered.

WATER SUPPLY AND SANITARY MATTERS.

CARNOUSTIE, N.B.—The new works of water supply for this village were inaugurated by Mr. Barclay, M.P., on Monday week. Mr. McCulloch, C.E., of Dundee, made the preliminary investigations and report, and Mr. J. F. Bateman, C.E., of Westminster, was consulted, and approved of the proposed source of supply. The works are situated about two miles north of Carnoustie on the lands of the Earl of Dalhousie, to the south of Panmure House. The scheme is an underground one—that is, the water instead of being obtained on the surface in the usual way, is all collected in a novel manner below ground. The nucleus of the supply consisted of the Brax Spring, one of the feeders of the Lochy Burn, and by means of some 1,500 lineal feet of adits cut into the upper bed of the old red sandstone formation at an average depth of 12 ft., an abundant supply has been obtained, the adits serving as natural reservoirs for the storage of about 7,000,000 gallons of water. Besides this, a reservoir, with a capacity of 6,000,000 gallons, being 20 ft. square by 20 ft. deep, is provided a quarter of a mile away. The springs yield about 300,000 gallons per day, and the water passes by gravitation into the village. Offers were invited for the construction of the works in five separate contracts; but the tenders of Mr. George Mackay, contractor, Broughty Ferry, were accepted for the whole of these. Messrs. Robert Maclaren and Co., Eglinton Foundry, Glasgow, supplied the iron pipes, and the Glenfield Company, of Kilmarnock and Paris, supplied the special castings, sluice, and air-valves. Mr. Robert Gellately, Loches, acted at the outset as inspector of works, but resigned from ill-health, when Mr. David Peter, Dundee, took his place. The total outlay has been about £7,000.

NEWHAVEN AND SEAFORD.—The experimental borings for a supply of water to the districts of Newhaven, Denton, Seaford, Blatchington, and Bishopstone by a private company have just been crowned with success. The well was sunk some

months since on the Bullock Hill, Blatchingdon, to a depth of 175ft., and was pronounced on analysis to be of excellent quality, but the quantity yielded was quite insufficient for the purposes of a scheme. The engineers then had headings driven in various directions for total lengths of 500ft., with heights varying from 6ft. to 26ft., but the supply was still insufficient. It was, therefore, resolved to continue the boring, and at a further depth of 116ft. an abundant supply was struck, and has been shown to give, on pumping, some 400,000 gallons per 24 hours, four or five times the quantity required. The directors last week accepted the tender of Mr. Lutley for laying the mains within four months. Messrs. Easton and Co. are the engineers.

Our Office Table.

THE *Times* concludes an article in its issue of yesterday on Mr. Street, by declaring that "there are already indications of a general dissatisfaction with all architecture in which some purely ideal beauty leads the way. Are we," asks our contemporary, "to go on for ever hampering or blocking our Christian auditories with pillars, aisles, and deep chancels? Are we to impress on the building itself the distinctions of rich and poor? In no other kind of building do we retain pillars if they can be avoided; and in the present state of the constructive art they can always be avoided at a slight extra cost. There can be no reason for so neglecting the form of the basilica, certainly the first form of the Christian church. That, of course, involves a row departure as to style, but it need not be either elaborate or expensive. Indeed, the simpler the basilica the better."

THE works in connection with the Channel Tunnel experiments at the new heading in Shakespeare's Cliff, Dover, have been so successful that the first quarter of a mile is now completed. The engineers have been able to gradually increase the rate of progress, and have now attained the average of 36ft. per day. The soil is quite dry in this boring, there being a total absence of the springs which occasioned so much delay and expense in the Abbot's Cliff heading. About 80 men are employed on the works. They are at work in two night-and-day shifts; but it is proposed shortly to have an extra shift, all working eight hours each, to expedite the work. No boring is done on Sunday, the men being chiefly employed on that day in lengthening the double line of metals on which the trolleys carrying the output travel. The tunnel has now advanced several yards under the sea in the direction of the Admiralty Pier.

THE leaning tower of the church of St. Lambert at Munster, in Westphalia, is being pulled down, as several large cracks were discovered at its base, and the inhabitants of the neighbouring houses have been obliged to leave. The scaffolding used for the completion of the towers of Cologne Cathedral has been erected, and the first part taken down was the wooden cupola, beneath which stood for upwards of three centuries the iron cages in which were exposed the bodies of the three Anabaptist leaders who had been put to death on the 22nd of January, 1536. One of these was John of Leyden, the fanatic who proclaimed himself king and prophet, and who, after having been taken prisoner by the Bishop of Munster, whom he had dispossessed, was carried about from town to town, and eventually put to death with two of his associates at Munster. The bodies were then placed in iron cages, and the cages were hoisted up to the top of the tower of St. Lambert's Church, where they remained until last week. They will, together with many instruments of torture, be exhibited in Munster until the completion of the new tower, which is to be built out of the materials of the old one.

THE surveyor to the vestry of St. Luke, E.C., Mr. A. Allen, jun., has reported that after careful inspection of the wood-paving in Bunhall-row, he finds evidence of a somewhat rapid deterioration. This he attributes to the fact that the levels of the thoroughfare have so little variation that the water cannot escape so readily as in a case where a moderate gradient exists. Hence the wood becomes charged with an undue proportion of moisture, which, combined with the heavy traffic to which the paving

is subjected, materially assists in the deterioration observed. The work reported upon was executed in the winter of 1875-6. The surveyor suggests that to prevent this deterioration, boys be stationed in the thoroughfare during the day to sweep up and collect the horse-droppings, as in many of the City thoroughfares. The vestry has resolved to call upon the Asphaltic Wood Paving Company, under their maintenance contract, to execute works of re-instatement in the thoroughfare, but has deferred the consideration of the surveyor's suggestion to employ boys to keep the paving constantly swept.

IN 1800 (remarks the *Farmer*) there were 564 inhabitants to every 100 houses. In 1880 there were 537 inhabitants to every 100 houses. We take no note, in either case, of houses uninhabited or in course of building. In 1800, the uninhabited houses in England and Wales amounted to 3.1 per cent. of the inhabited houses. In 1880, the proportion had risen to 7.8 per cent. When we compare the visible improvement in size and accommodation which has taken place in both urban and rural domestic architecture with the fact that there were 4.8 per cent. fewer inhabitants in every average house, and that there are more than double the proportion of empty houses from which to choose a residence, it will, we think, be tolerably clear that the accommodation for the individual now offered is in advance of that which was the case at the commencement of the present century; and, where an architect has been employed, an advance also in the direction of comfort.

IN a gloomy, ill-lighted, and somewhat evil-smelling booth at the corner of Blomk-street, Sheffield, according to a local paper, is a model of Ely Cathedral, carved in English oak three centuries old, by M. G. Strapps and Son, of Wisbech. The writer asserts that the model is marvellous, and it is a shame that so choice a specimen of patient toil should be shown in a place so unworthy of the work. It is 8ft. 4in. long, 4ft. wide, and 3ft. 6in. high. More remarkable than the size is the carefulness of the detail in every part.

AT the last meeting of the British Association, at York, in September last, Dr. Phené, F.S.A., &c., read a paper before the Anthropological Section on "The Serpent Mounds on the Scottish Border." A Scottish gentleman (Mr. Allan Cochrane, manufacturer, Fairknowe) had his attention directed to Dr. Phené's paper, and, aware of the existence of a seemingly artificial mound in Gala Park, near Galashiels, communicated with Dr. Phené, who last week came down from London to make a personal examination. It was a circular, flattened mound, 27ft. in diameter. The proprietor, Mr. Scott, of Gala, was made aware of the circumstances, and readily consented to the opening up of the mound, giving the assistance of his workmen for the purpose. Dr. Phené said if sacrificial or other barbarous forms of worship had been practised a deposit of charcoal would be found in the centre. A cutting was made, and exactly in the centre and 3ft. below the surface, the expected charcoal deposit was found. Dr. Phené's report will, no doubt, be awaited with interest.

THE "Wandering Exonian" gave his usual Christmas feast to some of the aged poor of his adopted city on Monday last. The gathering partook also of the nature of a "house-warming," being the first day of a new residence being used by its owner Mr. Harry Hems. The "Wandering Exonian" occupied the head of the table, and was faced by W. Daniel Ross, of Dix's-fields. The ancient guests assembled at one o'clock, and did justice to the substantial joints of beef, and the roasted turkeys, geese, fowls, &c. The host gave "The Health of the Mayor and Mayoress," and the Mayor, in responding gave, in very complimentary terms, "The Health of the 'Wandering Exonian.'" Dancing followed in the evening; the mistletoe bough which hung from the centre of the ceiling was well patronised, and all the ancient dames present, some of whom were particularly comely—kissed the blushing "Exonian" beneath its berries.

DEALING with Mr. Street's more personal characteristics, a correspondent of the *Times* remarks that it may be said that the mediæval spirit which gives such life to all his works was no less conspicuously present in his way of working. His independence of others was

absolute, his reliance on himself implicit; as far as he, indeed, from putting himself in the least degree in the hands of his assistants that was probably a standing grievance with him that any such assistance was required. For considerable time he drew all his full-size details in brown ink, in order that the time spent by his clerks in inking in his pencil lines might be economised. In this way, also, he insured getting absolutely what he wanted. The deviation of a hair's breadth from his own pencil line caught his eye at once, and he would say instantly, "That was not my drawing." This points to a self-reliance and trust in his own powers which, justified as it was, must have had no small share in impressing others with his masterly qualities. His complete personal superintendence of every smallest and least important detail has been equalled only by those predecessors whom he set himself so earnestly to emulate. But in one important particular he did differ widely from his prototypes—namely, that, whereas they had, as a rule, devoted a lifetime to one building, he was enabled by the times he lived in to attend most minutely to the Courts of Justice, Christ Church Cathedral, Dublin, and other large works at one and the same time, without any detriment to them.

M. MASPERO, the director of the Egyptian Museums, has determined on opening all the Pyramids that have not yet been explored, and on further searching those that are not thoroughly known. Among the Pyramids situated on the borders of the Libyan desert is that of Meydoum, said to be the most mysterious of all. It appears that its entrance had never been discovered. It is to this Pyramid that M. Maspero is now devoting his attention. By removing some of the ground on the north side of the artificial mound which surrounds the Pyramid he has succeeded in uncovering all the points where an opening might be revealed, and the result has shown that his calculations were well founded. Thirteen days of active labour, with skilled workmen, have sufficed for the discovery of a secret which was believed to be undiscoverable. The spades of the fellahs have exposed to view the opening, which is situated nearly at the top of the artificial mound. On entering the Pyramid the visitor passes through a corridor, admirably constructed, which takes him about forty yards in a gentle decline, as is the case in the great Ghizeh Pyramid. Here, for the moment, he is stopped by the debris, which is being rapidly cleared away.

THE timber of the pear-tree is of a yellow colour. Gerard says the timber of the wild-pear is so very firm and solid, and good to be cut into moulds. The plates for his "Herbal" were cut out of this wood, as were, says he, breast-plates for English gentlemen. In the present day, according to *Science Gossip*, it is much used by the turners and pattern-makers; the blocks with which the designs for floor-cloths are painted are made from pear-wood. When dyed black it can scarcely be distinguished from ebony. Handles for carpenters' tools, measuring rules, &c., are made from this wood. The wood of the pear makes excellent fuel, giving out an intense heat with a bright flame.

THE mural decoration of the sanctuary at Hughenden Church, which has been in hand since October 11, has been completed. The work consists of a dado of dark red, bearing a vine pattern in lighter red with golden grapes; above the string-course are the four Greater Prophets, then a band of pomegranates, and then the four Evangelists on gold ground in rich canopy work, while round the head of the window are medallions, with the nine orders of the angels and the seven gifts of the Spirit, all the figures looking towards the central figure of the east window, our Lord in Majesty, surrounded by the glorious company of the Apostles; the goodly fellowship of the Prophets; the noble army of Martyrs; the four Latin Fathers; the four Greek Fathers, and the British Bede and Edward the Confessor, as representing the Holy Church throughout all the world. Around the altar runs a band of gold on which is represented the wheat and the passion-flower, while the reredos is a mass of elaborate decoration in gold and black inclosing three panels of sequoia wood, bearing the lily, frankincense, and rose, exquisitely painted. The rest of the wall is covered with the vine, pomegranate, olive, frankincense, hyssop, lily, and fig.
